feet, three on the hind ones, and a yellowish belly. It is a native of Brazil, Surinam, and Guinea. 3. The leporinus has the same characters with the former; only the belly is white. It is found in Java and Sumatra. 4. The citellus has a short tail, an ash-coloured body, and no ears. It is found in Bohemia, &c. below ground. 5. The lemmus, has a short tail, five toes on both fore and hind-feet, and the body is variegated with green and yellow. They are found in the Lapland mountains under little hillocks, and feed solely on vegetables. 6. The paca, has a short tail, five toes on each foot, and there are three yellowish lines on each side. It is a native of Brazil. 7. The marmota has a short hairy tail, round ears, and gibbous cheeks. It digs deep holes in the earth with amazing quickness; sleeps profoundly during the winter; lifts its food to its mouth with the fore-feet; often sits erect; it is easily tamed, and is found in Switzerland. 8. The monax has a hairy tail, an ash-coloured body, roundish ears, and four toes on the fore feet and five on the hind ones. It is a native of America. 9. The cricetus has a tail of a moderate length, round ears, a black belly, and reddish sides, with three white spots. This animal digs deep caverns in the earth, divided into many different cells, in which it deposits and preserves large quantities of fruits and grains. The female brings forth six young ones twice in the year, each of which lives in a separate cell. They are hunted for food, for their skins, and even for the quantity of grain found in their cells. It is a native of Germany. 10. The terrestris has a hairy tail, with four toes on the fore-feet, and five on the hind ones, and ears shorter than the hair. This animal, which is about half the size of a rat, digs in the gardens like a mole, and eats the bark off the roots of trees, &c. It swims in ditches, and devours young ducks in the ponds. It is a native of Europe. 11. The amphibious has a long hairy tail, with palmated feet. It digs in the banks of ditches and under the roots of trees, and feeds upon vegetables. It is found both in Europe and Africa. 12. The rattus, or rat, has a long naked tail, four toes on the fore-feet, and five on the hind ones, and a claw on the large toe. This animal infests the houses every where through Europe, and is devoured by cats and other animals of the same class. It is reported by several authors, that rats were originally transported from America in a ship belonging to Antwerp. 13. The musculus, or common mouse, has a long naked tail, four toes on the fore-feet and five on the hind ones, but has no claw on the large toe. This animal is a native of Europe, feeds upon grain and flesh of all kinds. 14. The avellanarius has a long hairy tail, a reddish body, a white throat, and the hind toes have no claws. It frequents the woods of Europe, feeds upon nuts, which it lays up in the earth, and sleeps during winter. 15. The quercinus has a long hairy tail, with a black ring under the eyes. It is a native of the fourth of Europe. 16. The gregarius has a tail about one third of the length of its body, and somewhat hairy; the body is of a greyish colour, and the legs are white.

It is a native of Germany. 17. The *fyriaticus* has a tail of a middling length, four toes on the fore feet, and five on the hind ones; the body is grey, interspersed with black hairs, and the belly is white. It is found in the gardens and woods of Europe. 18. The *striatus* has four toes on the fore-feet, and five on the hind ones; it has longitudinal streaks on the body, with white spots. It is a native of India. 19. The *longipes* has a long covered tail, four toes on the fore feet, five on the hind ones, and very long thighs. It is found in the torrid zone. 20. The *jaculus* has a long fleecy tail, with very long thighs, and short fore-legs. It walks on its hind-feet only, and has a jumping motion. It is found in Arabia, Egypt, &c. 21. The *volans* has a long hairy tail, four toes on the fore feet and five on the hind ones, and the skin from the ears to the tail is extended like wings, by which it is enabled to fly. It is a native of Virginia and Mexico.

MUSA, the PLAIN-TREE, in botany, a genus of the polygamia monœcia class. The calix is a spathe: the corolla consists of two petals; one of them straight and toothed; and the other is concave, short, and furnished with a nectarium. It has six filaments, and one stylus. There are four species, all natives of the Indies.

MUSCA, in zoology, a genus of insects belonging to the order of diptera. The mouth is furnished with a fleshy proboscis, and two lateral lips; it has no pappi. There are 129 species, principally distinguished by peculiarities in their feelers.

MUSCADINE, a rich kind of wine, of the growth of Provence and Languedoc, in France.

MUSCLE, in anatomy. See *ANATOMY*, p. 192.

MUSCLE, in natural history. See *MYTULUS*.

MUSEUM, a name which originally signified a part of the palace of Alexandria, which took up at least one fourth of that city. This quarter was called the Museum, from its being set apart for the muses and the study of the sciences. Here were lodged and entertained the men of learning; who were divided into many companies or colleges, according to the sciences of which they were the professors; and to each of these houses or colleges was allotted a handsome revenue. The foundation of this establishment is attributed to Ptolemy Philadelphus, who here placed his library. Hence the word Museum is now applied to any place set apart as a repository for things that have an immediate relation to the arts.

The Museum at Oxford, called the Ashmolean Museum, is a noble pile of building, erected at the expense of the university, at the west end of the theatre,

at which side it has a magnificent portal, sustained by pillars of the Corinthian order. The front, which is to the street, extends about sixty feet, where there is this inscription over the entrance, in gilt characters, *Museum Ashmoleanum, schola naturalis historie, officina chymica.*

It was begun in 1679, and finished in 1683, when a valuable collection of curiosities was presented to the university by Elias Ashmole, Esq. which were the same day deposited there. And several accessions have been since made to the Museum; among which are hieroglyphics and other Egyptian antiquities, an entire mummy, Roman antiquities, alars, medals, lamps, &c. and a variety of natural curiosities.

The British Museum in London is a large, beautiful, and magnificent building, and the noblest cabinet of curiosities in the world. This edifice was erected in 1677, and was called Montague-house, from having been the town residence of the dukes of Montague. In the year 1753, the British parliament having passed an act for purchasing the Museum of the late Sir Hans Sloan, and the collection of manuscripts of the late lord Oxford, called the Harleian Library, for the use of the public; 26 trustees were appointed and incorporated, to provide a repository for those and some other collections, which repository was to be called the British Museum. These trustees elected fifteen other trustees; and having bought Montague-house, fitted it up for the reception of these collections: they also appointed officers to superintend the museum; and having ordained certain statutes with respect to viewing the collection contained in it, the public were admitted to view it in 1757.

MUSES, certain fabulous divinities amongst the pagans, supposed to preside over the arts and sciences: for this reason it is usual for the poets, at the beginning of a poem, to invoke these goddesses to their aid. Some reckon the muses to be no more than three, *viz.* Mneme, Aœde, and Melete; that is, memory, singing, and meditation; but the most ancient authors, and particularly Homer and Hesiod, reckon nine; *viz.* Clio, which means glory; Euterpe, pleasing; Thalia, flourishing; Melpomene, attracting; Terpsichore, rejoicing the heart; Erato, the amiable; Polyhymnia, a multitude of songs; Urania, the heavenly; and Calliope, sweetness of voice. To Clio, they attributed the invention of history; to Melpomene, tragedy; to Thalia, comedy; to Euterpe, the use of the flute; to Terpsichore, the harp; and to Erato, the lyre and late; to Calliope, heroic verse; to Urania, astrology; and to Polyhymnia, rhetoric.

MUSHROOM, in botany. See *FUNGUS*.

M U S I C K.

MUSICK is one of the seven sciences commonly called liberal; and is comprehended also among the mathematical, as having for its object discrete

quantity or number, but not considering it in the abstract like arithmetick, but in relation to time and sound, in order to make a delightful harmony: Or it is the art of disposing

disposing and conducting sounds considered as acute and grave; and proportioning them among themselves, and separating them by just intervals pleasing to the sense.

Mr Malcome defines it a science that teaches how sound, under certain measures of time and tune, may be produ-

ced; and so ordered and disposed, as either in consonance (*i. e.* joint-sounding,) or succession, or both, they may raise agreeable sensations.

From this definition, the science naturally divides into two general parts, *viz.* theoretical and practical.

PART I. THE THEORY OF MUSICK.

CHAP. I. OF MUSICAL SOUNDS.

AXIOM I. The ear is the sole judge of sound. Every sound is not a musical sound. For to this two things are required: first, That the sound please the ear; secondly, That it be within a certain compass. A musical sound is clear, uninterrupted, and uniform; and ought not to exceed the power of the ear to judge of it.

For sounds, very deep or very high, are not easily distinguished, but by an ear very conversant in musick.

Sound being a simple idea, cannot be defined but by an imperfect description of its cause; which is an undulatory motion of the air, communicated by the vibration of the parts of bodies to the organ of hearing.

The diversities of sounds, and their proportions, are perfectly discerned by the ear, are the object of the theory of musick, the grounds and principles of the practice, as well as the causes of pleasure in the sense and imagination.

These diversities of sounds are expressed by the terms high and low, acute and grave, or sharp and flat. Hence, from any given sound, we can conceive a succession of them; wherein the last in order is more acute than the foregoing; and this series is called notes ascending.

Or, on the contrary, when, in a succession of sounds, the last in order is more grave than the former; this series is called notes descending.

AXIOM II. From this order of notes ascending and descending are deduced all the proportions of sounds; the properties of the same proportions; and the relations which arise out of their various combinations and successions. These include the whole business of harmony and melody; and the knowledge of them is the ground work or basis of the science of musick.

COROLLARY I. Hence nothing can be admitted in musical composition which doth not immediately depend on the foregoing axiom, and which cannot be demonstrated from it.

SECT. 2. Of the DIVERSITY of SOUNDS.

THE diversity of sounds succeeding in the natural order is not however extended through any number of sounds which may be expressed by a musical instrument, or even by the human voice. For universal experience, conducted by the judgment of the ear, hath demonstrated and ascertained the number seven to comprehend all the variety that musick is capable of affording. Therefore, the number eight is the bound or limit of the materials of musical composition; and this eighth note or sound is called an octave.

This octave may be conceived as unity, or the first note of another series ascending or descending.

This series, though it may be repeated at pleasure, must still come under the restriction above mentioned; which is, that it must not exceed the power of the ear to judge of it. The greatest compass of the human voice will scarcely reach above two octaves, or fifteen notes. Instruments are framed with more, to answer the most interesting purpose of musick, which is variety.

The seven sounds in music are named from the first seven letters of the alphabet, *viz.* A, B, C, D, E, F, G.

The distance between any two of those, whether immediate or remote, is called an interval. And every interval is named from the natural numbers; beginning at unity.

In naming of an interval, it is always understood of the ascending notes; and both terms are inclusive. Thus AB is called a 2d, AE a 5th, BE a 4th, EG a 3d, AA an 8th or octave; and so of the rest.

We proceed now to lay down an exact description of all the intervals in music. For from the knowledge of these are discovered all the proportions which constitute harmony; and upon which the whole superstructure of musick is raised.

First, of the intervals of sounds lying in their natural order. Of these there are seven intervals, named either the greater tone, the lesser tone, and the half-tone or semitone. See the *Musick Plates*, N^o. 1, 2.

N ^o . 1.	Interval of a					
	Major	Minor	Semitone	Major	Minor	Semitone
N ^o . 2.	Interval of a					
	Major	Semitone	Minor	Major	Semitone	Minor

In this series of 8 notes are contained 5 whole tones; three greater, and two lesser; and 2 semitones. Reducing them therefore to the lowest denomination, they will be found to contain 12 half-tones; and inclusively 13. Every octave then contains 13 half tones; out of the various combinations of which arise the several concords and discords, as will be shewn in its proper place. The lesser tones are alike divided into half tones, as are the greater. We shall therefore, for brevity sake, hereafter use the distinction only of whole tones and half tones: the reason for which shall be assigned below.

From the inequality in the order of these intervals we draw the following corollary.

COR-

COR. II. Harmonical proportion is of a species different from all other proportions, and can be demonstrated only from principles peculiar to itself. This will be seen when we come to shew the method of dividing a line harmonically; as well as from the proportion stated in numbers.

The first of the notes in the examples above is called the key-note, or key. Notwithstanding the intervals may be reckoned from any given note; yet it will answer our purpose better to begin with the key.

In the first example,

The first interval, or distance between the key and second,	contains 2
Between the 2d and 3d	2
3d and 4th	1
4th and 5th	2
5th and 6th	2
6th and 7th	2
7th and 8th	1

In the second example,

The first interval, or distance between the key and second, contains 2 semitones.

Between the 2d and 3d	1
3d and 4th	2
4th and 5th	2
5th and 6th	1
6th and 7th	2
7th and 8th	2

From this comparison of the two series, it is evident there is but one difference, and this arising from the order of the notes, or place of the semitone. For if you begin to read the second series at the interval between the 3d and 4th, the semitones will be found exactly in the same order as in the first example.

In the first example, the first semitone falls on the 4th note, or that which is next above the 3d to the key; which 3d is 5 half tones above the key inclusively. In the 2d example, the half-tone falls on the 3d note; and is therefore itself the third to the key, and is four half-tones above the key inclusively.

This distinction of the place of the semitone is most worthy of observation, it being the only essential difference of tune, the ground-work of all that beautiful variety which may be introduced in the air or melody, as well as it is the principle or hinge on which turns the resolution of every discord. The key-note of every tune is that whereon the tune ends; which though it may be altered for variety in the upper part, yet the last note of the bass is ever the key.

When the 3d to the key is 5 semitones to the key, as in the first example, that tune is said to be composed in a sharp key. When the 3d to the key is 4 semitones to the key, as in the second example, the tune is in a flat key. And this, as was said before, is the only difference in tune.

This distinction of flat and sharp third holds good, not only in relation to the key, but likewise to every note in the scale of music. And in this light it is the foundation of composing in different keys, of changing the key in the same tune which introduces the so much desired variety in music; and of writing the same tune in

divers keys, which is called transposition. Hence we establish the following axioms.

AXIOM III. As the difference of the flat and sharp third to the key constitutes the key, and is essential to the tune: so no tune composed in a sharp key can be composed into a flat one, nor a flat into a sharp; for that would be altering the permanent nature of things.

The truth of this axiom will most evidently appear, when we shall, in the second part, or practice, have learned the art of transposition.

AXIOM IV. The great and constant object which must be sought after in music, whether in composition, or performance of thorough bass, is variety with uniformity. For the proportions already laid down, and the prodigious variety emerging from them, as they lie in the order of nature, before they are modified, divided or combined by art, do not only point out this variety to us; but the concords and discords likewise made out of these, and arranged by art, will not only not suffer us to recede from the established precept, but by a kind of sweet violence constrain us to pursue this darling object.

On the truth of this axiom is grounded the reason for the mixture of discord with harmony, and the occasion of this precept in playing thorough bass, namely, that the hands should as much as possible move in a contrary direction.

As to the place of the other semitone, which in the flat key is on the 6th, the reason shall be told in its proper place. And moreover, it must be observed, that the greater 7th in the sharp key, which causes the second semitone to fall on the 8th in that key, is also common to the flat key in many passages, but unexceptionably at the end of the tune, or close.

SECT. 3. Of the CONCORDS and DISCORDS.

OF the intervals standing in their natural order are compounded the greater intervals, namely, the concords and discords.

These are the next things to be considered. Now, to investigate the order of these, and their proportions to each other, we must have recourse to the original cause of sound; that is, to the tremulous motion of the air, excited by the percussion of some solid body, as a bell, string, or pipe.

This trembling of the air is in proportion quick or slow as the impression given it by the voice or an instrument. The quicker the trembling is, the more acute the sound; the slower, the more grave or flat. The same sound is the effect of the same degree of quickness of the air's motion continued. Hence a string sounding the same note to the end of its vibration, proves, that the vibrations are in equal times, from the greatest to the least ranges of its motion.

The shorter a musical string is, the quicker are its vibrations, and therefore the more acute the sound.

The longer a string is, the more slow are its vibrations, and so the more grave the sound.

Therefore, from the division of a musical string, the proportions of acuteness or gravity are computed. Hence we raise the following axiom.

AXIOM V. The quickness of the vibrations is reciprocal

4 L

↑

procal

proportional to the lengths. Thus in two strings of the same matter, and equal diameters; if one be double the length of the other, it will give half the quickness of pulses; that is, half the number of pulses in the same time: or, the lengths being as 2 to 1, the vibrations are as 1 to 2. On this axiom are demonstrated the order and proportions of the concords, as follows.

Proportion of the Octave.

C

A ————— B

Let AB, a musical string, be divided equally in C, and stopt there: CB will found an octave to the whole or open string AB. Now, CB, AB, are as 1 to 2: therefore, the vibrations are as 2 to 1; that is, the proportion of the octave or diapason is double, or 2 to 1. Q. E. D.

Proportion of the 5th.

C

A ————— B

Let AB be divided into three equal parts, and stopt in C; CB will found a 5th to the whole or open string. Now, CB is to AB as 2 to 3: therefore the vibrations are as 3 to 2; that is, the proportion of the 5th, or diatense, is sesquialteral, or 3 to 2.

Proportion of the 4th.

C

A ————— B

Let the string be stopt in C, which is a 4th part of the whole: CB will found a 4th to the whole AB or open string. Now, CB is to AB as 3 to 4: therefore the vibrations are as 4 to 3; or, the proportion of the 4th, or diatessaron, is 4 to 3.

Proportion of the sharp 3d.

C

A ————— B

Stop the string in C, the 5th part: CB will found a greater 3d to AB. But CB is to AB as 4 to 5. Therefore the vibrations are as 5 to 4; or, the proportion of the sharp 3d is as 5 to 4.

Proportion of the flat 3d.

C

A ————— B

Stop in C the 6th part: CB will found the lesser or flat third. But, &c. Therefore the proportion of the flat third is as 6 to 5.

Proportion of the greater or sharp 6th.

C

A ————— B

CB $\frac{2}{3}$ ths of AB will found the greater 6th. Therefore the proportion of the sharp 6th, is as 5 to 3.

Proportion of the lesser or flat 6th.

C

A ————— B

CB, $\frac{4}{5}$ ths of AB, founds the lesser 6th. Therefore the proportion of the flat 6th is as 8 to 5.

If these divisions of the string, whose numerators are the same, or unity, be set down in fractions, in the natural order of numbers, thus $\frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}$, &c. and reduced to a common denominator, the harmonical proportions will appear in the same succession of concords, as investigated by found in the division of the same line; and the numerators, being by this reduction as whole numbers, will stand thus, 60, 40, 30, 24, &c. For the common denominator, 120, answering to the whole or open string; the relative proportion of the same to the first fraction, and the relative proportion between each two successive fractions, will express the proportion of the harmonic chords. Thus $\frac{1}{2} : \frac{1}{3} :: 2 : 3$ or 8th. $\frac{1}{3} : \frac{1}{4} :: 4 : 3$ or 5th. $\frac{1}{4} : \frac{1}{5} :: 5 : 4$ or sharp 3d. Hence we discover relative harmonical proportion in numbers: which is, As the first is to the third; so is the difference of the first and second to the difference of the second and third. For, reducing the first three numbers to the lowest terms, and inverting, they will be 2, 3, 6. Now 2:6::1:3. Again, reducing the second three, they will be 3, 4, 6. Now 3:6::1:2. Wherever this proportion obtains, the numbers bear harmonical or musical relation. Further, the rectangle, or quotient of the first and third numbers multiplied, being divided by the excess of twice the first above the second, finds a fourth proportional. Thus 3, 4, 6, given as above; 3 multiplied by 6, gives 18: which divided by 2, the excess of twice 3, the first above 4 the second, gives 9, the fourth musical proportional. Thus 3, 4, 6, 9: And of these, the first is to the fourth, as the difference of the first and second is to the difference of the third and 4th. So 3:9::1:3.

The harmonic proportion of three numbers in this natural succession of fractions, extends as far as the chord of the flat 3d. Which third, being $\frac{2}{3}$ of the whole number, limits this equality of proportion, seeing that the number 7 is no aliquot part. But as to the fourth proportional, it cannot be found even from that number which expresses the sharp 3d, which is still of shorter extent. This limitation of proportion then explains the extent of harmony, and likewise becomes the principle of the same; as will be seen in the definition of harmony.

Hence it is evident, the remaining concords of the sharp 6th, which is $\frac{5}{3}$, and of the flat 6th, or $\frac{8}{5}$, are not included in this equality of proportion.

These are the concords, their order and proportions; any one of which sounded together with the open string, is concordant with it, and produces harmony.

Example of the names and order of the intervals in concord with the open string or bass, and the semitones contained in each, *Musick Plates*, No. 3.

Again, two of these concordant intervals, namely, the
5th and ——— 8th
Sharp 3d and ——— 8th

Flat

Flat 3d and — 8th
 Sharp 3d and — 5th
 Flat 3d and — 5th
 Sharp 3d and Sharp 6th
 Flat 3d and Flat 6th
 6th and — 4th
 Flat 6th and — 4th

sounded with the open string, or bass note, are concordant all together; and therefore produce harmony.

Example of two concurring with the open string or bass. No. 4.

Next follows an example of three concurring with the bass. No. 5.

Having thus discovered the concords, their order and proportions; it is worth remarking, that the first concord, or 8th, which arises from the most simple division of a line, is the most perfect concord; the 5th is the next perfect concord; and so of the rest, in the order they have been found by the division of the string. For the nature and perfection of the 4th, accounted by some a very imperfect concord, shall be explained in the corollaries of the demonstration of the harmony, in Part II. on practice.

The 8ths and 5ths then are called the perfect concords. The 3ds and 6ths imperfect concords. The 4th, of a middle nature between the others, may be called an improper concord; for this reason, that with the 6th, with which it is always accompanied in harmony, though it make perfect harmony with the given note, yet they change the chord into that of the 4th to that note.

Likewise the 6th, whether joined with the 3d or 4th to the given note, tho' it make perfect harmony with either, yet they change the chord into that of the 6th or 4th to the same note.

Hence the reason why the 6ths are more imperfect concords than the 3ds.

From the order and perfection of the concords thus discovered; we deduce the following corollary

COR. III. The most perfect harmony is that which will be produced by the perfect concords, namely, the 3d, 5th, and 8th. Thus No. 6.

From the foregoing corollary, we are able to give a just definition of harmony. HARMONY consists in one certain invariable proportion of distance of four sounds performed at the same instant of time, and most pleasing to the ear.

These proportions of the first series are called simple concords. If the notes of a second series be added to the first octave, the proportion of any two concurring notes compounded with the octave retains the name and nature of the simple concord; as a tenth, compounded of an octave and third, is called a third; a twelfth, compounded of an octave and 5th, is called a fifth; a fifteenth, compounded of two octaves, is called an octave, or double octave. And so on to a third series.

These are the compound concords.

All other proportions sounded together are harsh and disagreeable to the ear; and are for this reason called discords.

From the compounding and dividing the proportions delivered, not only the harmonical intervals are computed, but the discords likewise.

And this the following calculations demonstrate.

The proportion of the octave is the proportion of the 4th and 5th: for, by compounding $\frac{4}{3} = \frac{16}{12}$, or $\frac{2}{3}$ the proportion of the octave.

Again, it is the proportion of the sharp 3d and flat 6th: for, $\frac{8}{4} \times \frac{4}{3} = \frac{40}{12}$ or $\frac{10}{3}$ in its lowest terms.

Again, the flat 3d and sharp 6th: for, $\frac{6}{3} \times \frac{4}{3} = \frac{24}{9}$ or $\frac{8}{3}$ the proportion of the octave.

Now, since the 4th and 5th, the 3d and 6th, as also the 2d and 7th, compounded, make the octave; that is, any two numbers making 9, the middle term or note being repeated, or common to both; it follows, that to fall a 4th or rise a 5th, as also to fall a 3d or rise a 6th, and to fall a 2d or rise a 7th, and the contrary, answers the same purpose of harmony; for they meet in the octave.

This observation will be of great use in setting the bass, and figuring the same, by producing that variety and contrary motion demonstrated necessary in the 4th axiom.

Proportion of the 5th.

The proportion of the 5th is the proportion of the sharp 3d and flat 3d; for by compounding $\frac{4}{3} \times \frac{2}{3} = \frac{8}{9}$ or $\frac{1}{9}$ the sesquialteral and known proportion of the 5th.

Proportion of the Sharp 6th.

The proportion of the sharp 6th is the compound proportions of the fourth and sharp 3d; for $\frac{4}{3} \times \frac{4}{3} = \frac{16}{9}$, or $\frac{4}{9}$. Of the flat 6th, the proportion is of the 4th and flat 3d; for $\frac{4}{3} \times \frac{2}{3} = \frac{8}{9}$ or $\frac{8}{9}$.

By the same manner of compounding are found the proportions of the concords of the 3ds; which shall be shewn when we shall have got the tones and semitones; which, as being discords, arise by dividing the harmonic proportions as follows.

PROPORTIONS of the DISCORDS proved.

Proportion of the Greater Tone.

The proportion of the greater tone is the difference of the 4th and 5th; for $\frac{4}{3} \times \frac{2}{3} = \frac{8}{9}$ the proportion of the greater tone.

Proportion of the Lesser Tone.

The proportion of the lesser tone is the difference of the 5th and sharp 6th; for $\frac{4}{3} \times \frac{4}{3} = \frac{16}{9}$ the proportion of the lesser tone.

Proportion of the Semitones.

The proportion of the semitone is the difference of the sharp 3d and 4th; for $\frac{4}{3} \times \frac{4}{3} = \frac{16}{9}$ the proportion of the semitone.

Having now the proportions of the tones and semitones, we are enabled to prove the proportion of the semitone, or flat 2d and sharp 7th to the 8th; as likewise all the remaining proportions, whether discord or concord: For, the 5th and sharp 3d, $\frac{4}{3} \times \frac{4}{3}$, give $\frac{16}{9}$ the greater 7th; and the sharp 9th and semitone $\frac{16}{9} \times \frac{16}{9} = \frac{256}{81}$ in its lowest terms $\frac{2}{3}$ the proportion of the octave.

To go on; The proportion of the sharp 3d is that of the greater

femitone, and one tone to the 5th; and thence by two tones and a femitone to the 8th. This is the order in a sharp key; where note, that the femitones are in the 4th and 8th places. No. 8.

In a flat key, the notes ascend according to the following example. No. 9.

One tone, a femitone, and two tones to the 5th; a femitone and two tones to the 8th.

In the next example, the same proportion of the flat third is illustrated by comparison with the instance in the sharp key. No. 10.

The number of the tones and femitones in both flat and sharp key are equal. The difference arises from the places of the femitone; which, in the flat key, are the 3d and 6th. This is that essential difference of tune already mentioned, which creates such variety in musical strains, as well as in the harmony. These are some effects of the femitone; others we shall see in its proper place.

The Chromatic Scale.

The chromatic rises by a tone and 5 femitones to the 5th, and thence by 5 femitones more to the 8th. Thus No. 11.

The chromatic scale, which is no other than the natural femitones in their order, except the first tone, is only used when mixed with the diatonic. That is to say, when a femitone, not belonging to the harmony of the key, is introduced in the middle of a tune. And this may be done by the note ascending by a femitone, or descending: in either of which cases, the key is changed in that part of the strain. This is the cause of great variety in the air; as well as it new-modulates the harmony. This is another effect of the femitone, on which turns so much variety and elegance. It must be executed by the composer with all the address and art imaginable. For this we must refer to the second part or practice; where will be given the rules for the mixture of the chromatic. Pieces of musick where it is frequently used, are now commonly called chromatic musick.

The diatonic scale being that which we are chiefly concerned to understand, as well as the first in order, and before any use of the chromatic can take place; we shall proceed to view it in another light, whereby we shall discover such properties of it as will be useful to the composer. Sharp key. No. 12.

From the key the thirds ascend, as in the above example, by one sharp 3d, two flat 3ds, two sharp 3ds, a flat 3d, and lastly another flat 3d on the 2d to the key.

All the 4ths being perfect, are like; except that one which falls on the sharp 7th; this is called a sharp 4th, or false 5th. No. 13.

All the 5ths are perfect, and therefore like; except that formed by the sharp 7th and 4th, which likewise is a flat 5th or sharp 4th. No. 14.

The 6ths stand thus: two sharp 6ths, one flat 6th, two sharp 6ths, two flat 6ths. No. 15.

There are but two greater 7ths which are the sharp 3d and sharp 7th to the key: they stand under the two femitones.

All the 8ths are perfect and alike.

From these theorems, and axioms, the 2d and 4th, we deduce this practical corollary.

COR. IV. The 3ds and 6ths are the intervals most frequently to be used in composition; the 8ths, 5ths, and 4ths most rarely.

The 4th being an improper concord, and the 7th a discord; we cannot ascertain their use till we come to the demonstration of the harmony and accompaniments of the discords in the 2d part.

On this 4th corollary is grounded the reason of forbidding two 8ths and two 5ths in consecution, either in composition, or performing thorough bass.

Next follow examples of the same in a flat key. No. 16, 17, 18, 19.

There are but two sharp 7ths which are the 2d and 5th to the key. They stand under the femitones.

All the octaves are perfect and alike.

It is evident to sight, that the intervals in the flat and sharp key do not in the least vary; except in the order they succeed each other, beginning from the key. And it is equally evident, that this variation is owing to the different places of the femitone.

This demonstrates what has been said in page 319. col. 1. concerning the femitone; and illustrates what is asserted in the 4th axiom, that variety, amidst uniformity, must be the great object attended to in musick, since that uniformity and variety both subsist in the very principles.

Let it be observed, that this uniformity is preserved by bringing in the flat 6th and flat 7th to the key. And this must of necessity be so, since they are the places of the femitone and lesser tone in the natural flat key wherein the example is set, according to the demonstration of the same.

For, by corollary 1. nothing can be admitted in composition which doth not immediately depend on the 2d axiom, and which cannot be demonstrated from it; namely, that the proportions of sounds, and their relations, must be deduced from the natural order of the notes. This is the true reason for introducing the flat 6th and flat 7th in every flat key.

The harmonic proportions and discords having been demonstrated from the division of a line in arithmetical progression; we shall, in the next place, try what are the effects of a musical string divided in geometrical proportion. No. 20.

Let AB, a musical string, be divided equally in C; CB, the half next the bridge, will sound an octave to the whole or open string, as we have shewn in the harmonic proportions.

Again, let CB be equally divided in D; DB will sound the octave to CB, or double octave to the open string, AB.

And thus, by an equal division of a string between either the nut and bridge, or stop and bridge; the half next the bridge will give the octave above continually.

But the same proportion is not preserved in the equal division between the nut and stop, or between any two stops. For the length of the octave to the open string, which is between the nut and stop, being equally divided; the half next the nut gives the sound of the 4th to the open string; and the half next the stop, or bridge,

4 M

.†

sounds

sounds the 5th, which two are the constituent intervals of the octave.

And the same division of the sounds is constantly preserved, if the length of an octave be equally divided between any two stops.

Again, the length of a 5th between two stops, or nut and stop, equally divided; the half next the bridge gives the greater 3d, the other half the lesser 3d.

And again, the length of the greater 3d, thus divided, gives the greater and lesser tone. And the greater tone's length, equally divided, gives the greater and lesser semitone. And the length of the greater semitone, equally divided, gives the sounds in proportion as 5 and 4. The greater interval being next the bridge, and so continually.

Hence the necessity of the greater and lesser tones and semitones in music is evident; and the truth confirmed, which is asserted in the 2d corollary.

Now, in the diatonic scale, wherefoever the semitones lie, that is, whether the air be in a flat or sharp key, the graver part of the tone will be the lesser semitone, and the acuter the great semitone; and in the chromatic, which ascends by semitones, the greater and lesser semitones will, for the same reason, succeed each other alternately. Wherefore, if any series of chromatic notes be removed a semitone higher or lower; it must happen, that the lesser semitone will succeed into the place of the greater, and the greater into the place of the lesser. Hence dissonances will happen in the diatonic scale, as being composed of the same materials with the chromatic, if the key be injudiciously changed by transposition. For, as the dissonance will be evident, if the transposition be by one semitone; so the disproportion will still appear, if the removal be by any odd number of semitones within the compass of the 4th.

As the proportions of the concords have been demonstrated from the division of a line; so are they likewise to be found in the geometrical proportions of solid bodies, and therefore may be illustrated by the same.

We shall begin with the proportion of the 8th.

The proportion of the 8th being the compound proportions of the 5th and 4th, is, by corollary of the 34th proposition of Archimedes, as the whole superficies of a right cylinder described about a sphere, to the whole superficies of an equilateral cylinder inscribed as 2 to 1. For, the circumscribed is to the spheric superficies as 12 is to 8 (by 32 of this,) but the spheric is to the inscribed as 8 is to 6 by this present proposition: therefore the circumscribed is to the inscribed as 12 is to 6, or 2 to 1.

In harmonic terms thus expressed: the 5th is to a given note or key as 12 is to 8; but the proportion of the 4th is as 8 to 6. Therefore, the proportion of the 8th is $\frac{12}{6} \times \frac{8}{8}$ as 2 to 1.

Again, the proportion of the 5th, and the next harmonic proportion arising out of the 5th, is beautifully illustrated in the admirable proportion of the sphere, right cylinder, and equilateral cone circumscribed about each other. The last proportion being invented by Andrew Tacquet; and that of the two first by Archimedes, as demonstrated in his 45th proposition in Tacquet's Euclid.

We cannot forbear transcribing at length this wonderful proposition, and demonstration of the same; for that on this proportion is erected the whole superstructure of harmonic chords.

ARCHIMEDES'S PROPOSITION 45.

THEOREM. An equilateral cone circumscribed about a sphere, and a right cylinder in like manner circumscribed about the same sphere, and the same sphere itself continue the same proportion, to wit, the sesquialteral, as well in respect of the solidity, as of the whole superficies. For, by 32d of this book, the right cylinder () encompassing the sphere, is to the sphere, as well in respect of solidity, as of the whole superficies, as 3 is to 2, or as 6 to 4. But by the foregoing, the equilateral cone circumscribed about the sphere, is to the sphere, in both the said respects, as 9 to 4. Therefore, the same cone is to the cylinder, both in respect of solidity and surface, as 9 is to 6. Wherefore, these three bodies, a cone, cylinder, and sphere, are, betwixt themselves, as the numbers 9, 6 and 4, and consequently continue the sesquialteral proportion, Q, E, D.

In harmonic terms expressed thus: the 5th is to the key as 3 is to 2, or as 6 to 4: but the 9th is to the key, (that is, the 5th to the 5th) as 9 is to 4; (for the 2d and its 8th $\frac{9}{2} \times \frac{8}{8} = \frac{9}{2}$): therefore, the same 9th is to the 5th as 9 is to 6. Wherefore these three tones, the 9th, the 5th, and the key, are, betwixt themselves, as the numbers 9, 6, and 4; and consequently continue the sesquialteral proportion, Q, E, D.

Therefore, the proportions of the key, the 5th and its 5th, being the same sesquialteral proportion continued, are the same proportions as that of the equilateral cone, right cylinder and sphere; the two first described about the sphere, Q, E, D.

On the proportion of these three is erected every other proportion of harmony; which we shall pursue one step further, forasmuch as these truths will be most manifest and established in the practice when we shall have delivered the rules of harmony.

The 5th divided arithmetically, or equally, gives, as hath been shewn, the greater 3d or next perfect concord: the sesquialteral proportion to which gives the greater 7th; for $\frac{1}{2} \times \frac{1}{2}$ gives $\frac{1}{4}$ the greater 7th, as demonstrated above.

Hence, from the sesquialteral proportion thrice repeated, namely, to the key, its 5th and 3d, we are furnished with the perfect harmony, or concords of the key and 5th; to which every harmonic proportion, where ever found, is analogous; that is, partaking of the nature, proportion, and relation of the key and its 5th. It is worth remarking in this place, that the members of these chords arise out of the proportions, as above demonstrated, by turns. The key being first supplied with one proportion; and then in its turn the 5th with the same. Wherefore, the mixture of the harmony of the key and 5th is scarcely separable: A truth which will abundantly discover itself in the practice, both in the rules of harmony, and in every other part of composition. On this is founded the following axiom.

AXIOM

AXIOM VI. These 5 tones therefore, namely, the key, the 3d, 5th, sharp 7th and 9th, are the foundation of the whole superstructure of musick.

We shall conclude this theory with the harmonical division of a line.

To divide a Line harmonically. No. 21.

A right line, A D, is said to be divided harmonically, if, being cut into three parts, A B, B C, C D, the case be so, that, as the whole A D (or Z) is to either extreme a or c :: so shall the other extreme be to the indeterminate part m; that is,

$Z : a :: c : m$
 $Z : c :: a : m$ } Wherefore $Z m = a c$.

And, to divide any given right line thus harmonically, as suppose A D: From either end of it draw a right line, as D G; make an angle with it, and of any length; con-

nect the end of this line with the other end A, by drawing A G; and then taking any point, as B, at pleasure, in the given line, there draw E F parallel to D G, and in it take B E equal to B F; then draw E G, and that shall find the point C required: and then calling, as above, the whole line Z, A B = a, B C = m, and D C = c, I say $Z : a :: c : m$.

For the triangles A D G, A B F, and B E C, are all similar; and consequently $A D : A B :: D G : B F ::$ or as D G: to B F = B E. But as D G: B E: C D: B C: (by working about the equal angles D and E, B C) wherefore, by equality, A D: A B:: C D: C B; that is, $Z : a :: c : m$. Q. E. D.

And from hence it is plain, that the ratio of the whole line A D, to the segment A B, may be taken at pleasure; but that the intermediate part B C must be less than either A B or C D.

PART II. THE PRACTICE OF MUSICK.

THE practice of musick is founded on the principles delivered in the theory. Its several parts are, composition, figuring the bass, melody, transposition, and singing by note.

Of these we shall treat separately in the above order.

Composition is the setting together two or more notes in harmony, to be sounded at the same time.

When in the succession of concords, in the parts, the notes of each part are of the same length, or time of sounding, the composition is called counterpoint.

When the succession of concords is by notes of different lengths in the several parts, it is called plain descant.

The mixture of discord and concord, by notes of the same or different lengths or time in the parts, is called figurate descant. Of these in their order: and first of counterpoint.

In order to attain more easily the art of composition, it is necessary to premise a few things concerning other affections of sounds; as the time or lengths of sounding the notes; the time of musick, or movement of the air; and the different cliffs wherein the parts of musick are usually written.

The following account of the proportions of the lengths of notes, the time and cliffs, being well understood by every one acquainted ever so little with musick, might well have been omitted in an essay of this kind; (where, instead of using repetitions, it is hoped we have offered to the public something new; at least in the manner of demonstrating the rules of composition, both in discord and harmony;) but that we would leave nothing in our power untold, which may contribute to form a complete musician.

The longest note, now generally in use in instrumental musick, is called a semibreve. Its time is as long as you can distinctly count for.

Out of the division and subdivision of the semibreve are formed the lengths of all other notes; according to the following proportions. No. 22.

A semibreve, whose time is as one, two, three, four, is as long

as }	2 Minims,
	4 Crotchets
	8 Quavers,
	16 Semiquavers.
	32 Demisemiquavers.

A dot after any note, signifies the time of such note must be lengthened to one half of the plain note. No. 23.

The proportions are thus;

A dotted semibreve is equal to 3 minims.

A dotted minim to 3 crotchets.

A dotted crotchet to 3 quavers.

And so of the rest.

Thus we are furnished with notes according to the odd and even numbers. And this naturally divides the time of any song or music into odd and even time.

COMMON TIME.

When the air moves according to the even numbers; and every bar is measured by beating the time into two equal and even parts, the musick is composed in common time: known by one of the following marks prefixed to the tune; as the letter C, having 4 crotchets in a bar; or $\frac{2}{4}$, denoting two crotchets in a bar.

TRIPLE TIME.

But when the musick moves according to the odd numbers, and every bar is measured by beating the time into two unequal parts, as two and one, the song is composed in triple time; which is known by one of these signs prefixed to the tune.

3, or $\frac{3}{4}$, for 3 minims in a bar.

$\frac{3}{8}$ 3 Crotchets in a bar.

$\frac{3}{16}$ 3 Quavers in a bar.

$\frac{9}{8}$ 9 Crotchets in a bar.

$\frac{9}{16}$ 9 Quavers in a bar.

The uppermost number being the numerator of a vulgar fraction; and the lower, or denominator, the aliquot part of the semibreve.

There is also another proportion of the length of notes in use. And this is, when three quavers are, by diminution

nation of their lengths, contracted into the time of 2 quavers, or one crotchet, constantly noted by the figure (3) over them.

And lastly, the most common movement of jiggs, which is by six or twelve quavers in a bar, have their bass, for the smoothness of the movement, often written in plain crotchets; 2 in a bar for the treble $\frac{6}{8}$; and four, marked thus C, for the treble $\frac{3}{4}$. It is plain, therefore, that all tunes in these movements truly belong to common time, since every bar is measured by the beating, or dividing it into even parts, as expressed in the bass.

A pause or rest in music, is a cessation of the sound, in one or more of the parts; or of all the parts together. Nothing hath a finer effect in music than a pause of all the parts judiciously made; or of one, or more of the parts, for the sake of imitation. The rests therefore are written down in the place of notes, and each note hath its own rest, which is of the same length with the note whose name it bears. Thus,

A semibreve rest is as long as a semibreve.

A minum rest as long as a minum.

And so of the rest.

The next thing to be considered is the cliff in which any part of the music is said to be written; according as the cliff is prefixed to each stave of the writing.

The use of the cliff is to ascertain the names of the notes; and to denominate that part of the music to which it is prefixed.

There are three cliffs, to answer and distinguish the three parts in music: The bass, or F cliff; the tenor, or C cliff; and the treble, or G cliff. No. 24.

The bass is so called, from its being the lowest part, or that wherein are set the graver tones.

The tenor, or middle part, hath its name from holding the bass and upper parts together. This will be clearly understood, when we shall have learned to compose in four parts.

The uppermost part is called the counter tenor in vocal music; and, in instrumental, the first treble.

The bass and treble cliffs are now constantly written in the same places as in the examples. The tenor cliff is often removed, according to the fancy of the composer or writer of music; to answer the convenience of the notes standing, as much as may be, within the compass of the five lines, or stave. Which convenience is the reason for the invention of the diversity of cliffs, as well as the uses already named. For it is easy to apprehend, that the natural tones, and their proportions, are invariably the same, whether expressed by the voice, or an instrument, however they may be distinguished by artificial signs. Observe, that the cliffs, according to their names, rise above each other by the interval of a 5th: thus the tenor is equally distant from each other part. For C is a 5th to F, as it is also a 5th below G.

CHAP. I. OF COMPOSITION IN COUNTER-POINT.

COMPOSITION in counterpoint is when, in the succession of concords in the parts, the notes of each part are of the same length, or time of sounding.

According to the 2d axiom, we shall begin with the

harmony of the key note; and proceed to demonstrate the harmony of the remaining notes of the octave in their natural order.

Demonstration of the harmony of the key.

The harmony of the key is the concord of itself.

The harmony of the key must be perfect harmony. Now, the notes concurring in perfect harmony, are, by corollary 3d, the 3d, 5th, and 8th: But these, with the key, are the concord of itself: Therefore, the harmony of the key is the concord of itself.

This demonstration is grounded on this evident truth; namely, that any other concord would, by the term, or name of it, in effect change the key; whereby the unity of the tune would be destroyed, and by this contradiction the author's meaning rendered unintelligible. The necessity of perfect harmony in the key being evident, no other sort of demonstration is required, nor indeed can be admitted.

PROB. Let it be required to set a bass to the notes of an octave ascending in G sharp. No 25.

Any one of the three notes in the bass is concurring, by corollary 3; but the 8th is preferable when it is the first or last note of the tune; for thus it best ascertains the key. The preference of either of the other two depends on the following rules.

First, The 5th cannot take place when the concord immediately preceding shall happen to be a 5th, the forbidding the consecution of 5ths being asserted in corollary the 4th.

Again, the movement of the bass ought generally to be by descending a 5th, or rising a 4th, 6th, or 8th, or any other great interval; thereby meeting the treble, and effecting variety and contrary motion of the parts; the established rules of harmony by the 4th axiom.

Lastly, The air of the bass must be consulted; and, if possible, an imitation of some foregoing passage in the upper part.

The application of these rules will decide which of the two or three notes is preferable in this or any other concord.

Demonstration of the harmony of the 2d.

The harmony of the 2d is the concord of the 5th.

The harmony of the key having been shewn, we must consider it as an immovable point, in relation to which we are to order the rest of our computations, consistent with the established principle of uniformity.

The 2d to the key immediately descending into the key, will have, for its next concurring note, the greater 7th; which at the same time ascends by a semitone into the key; to which 7th the 2d is a 3d.

For, by axiom 2, the combination of sounds are deduced from the natural order of notes ascending and descending. But the 2d and 7th can admit no other concordant note but the 5th to the key. For the 3d is discord with the 2d; and the 4th, 6th, and 8th discord with the sharp 7th.

Now, the 2d, 7th, and 5th are the concord of the 5th; therefore, the harmony of the 2d is the concord of the 5th. No. 26.

The

The 5th must always be taken at the close; or when the treble is descending into the key; for then the bass will fall a 5th into the key; which movement is called the great cadence. Otherwise the 7th or 5th may be taken indiscriminately; yet, under the restriction of the rules, (p. 326. col. 2.) for setting the harmony of the key.

Demonstration of the harmony of the 3d.

The harmony of the 3d is the concord of the key.

From the demonstration of the harmony of the key, the key will have its 3d; and, by inverting, the 3d will have the key. Now, the key and its 3d will admit no other concordant note but its 5th: For the 2d is discord to both, the 4th is discord to the 3d, and the 7th discord to the key; but the key, its 3d and 5th, are the concord of the key. Therefore, the harmony of the 3d is the concord of the key.

The 6th indeed, which is a 4th to the 3d, which is an improper concord, will, with the key, form the concord of the 6th; but the demonstration of the concord of the 6th in a sharp key, depending on another principle, as will be shewn in its place, can, for the same reason, bear no relation to the harmony of the 3d, which is a member of the key. No. 27.

The two notes in the bass may be taken indiscriminately; yet complying with the rules, (p. 326. col. 2.) But, if the 3d in the treble be prepared to descend into the key, by its passage into the 2d, then the 5th is more eligible; which falling an 8th for the next note, thence descends by a 5th into the key. This is the most striking movement of the bass; and, at the same time, the most common, at a final close in either flat or sharp key.

Demonstration of the harmony of the 4th.

The harmony of the 4th is the concord of itself.

In a sharp key, the places of the two greater 7ths are the sharp 3d and sharp 7th to the key: and, of the semitones, the 4th and 8th, or key; Therefore, the 3d is to the 4th as the sharp 7th to the key. Now, since by axiom 2d, the combinations are deduced from the natural order of the notes ascending and descending; the harmony of the 4th will be as the harmony of the key: But the harmony of the key is (by demonstration 1.) the concord of itself: therefore, the harmony of the 4th is the concord of itself. No. 28.

The notes in the bass may be taken indiscriminately: only observing the foregoing rules. If a close on the 4th be prepared from the 4th itself, either note will do: yet the key is preferable, in order to prepare for the great cadence.

Demonstration of the harmony of the 5th.

The harmony of the 5th is the concord of the key.

From the demonstration of the harmony of the key, the key will have its 5th; and, by inverting, the 5th will have the key. Now, the key and its 5th will admit no other concordant note than the 3d. For, the 2d and 4th are discord with the key and 5th; the 6th discord with the 5th, and the 7th discord with the key. But the key, its 5th and 3d, are the concord of the key:

therefore, the harmony of the 5th is the concord of the key. No. 29.

There is no exception in the choice of the bass notes; but the disallowance of the consecution of 5ths. But if there be a preparation for a close on the key, and the 5th stand in the bass; in order to make the great cadence, the 5th will have its own concord. This depends on the demonstration of the 2d.

Demonstration of the harmony of the 6th.

The harmony of the 6th is the concord of the 4th.

From the demonstration of the 4th, its harmony is its own concord. The 4th, then, will have its 3d; and, by inverting its 3d (that is, the 6th) will have the 4th. Now, the 4th and 6th will admit no other concordant note than the 8th: For the 2d is, (with the 4th and 6th,) a discord, as will be shewn in the demonstration of the discords. The 3d and 5th are discord to the 4th, and the 7th to the 6th. But the 4th, 6th, and 8th, are the concord of the 4th: therefore, the harmony of the 6th is the concord of the 4th. No. 30.

Either note in the bass may be taken at will. But if there be a preparation for a close on the 4th, the second note, or key, is preferable, for the reasons assigned in the demonstration of the 4th, which is, to make the great cadence, prepared by the bass, first descending an 8th, and thence a 5th, into the 4th, or close.

Demonstration of the harmony of the 7th.

The harmony of the 7th is the concord of the 5th.

The harmony of the 7th is part of the harmony of the 2d, (by demonstration 2.) but the harmony of the 2d is the concord of the 5th: therefore the harmony of the 7th is the concord of the 5th. No. 31.

If the 7th, or treble note, precede a close on the key, the first note in the example must be the bass note, in order to make the great cadence.

The 8th being the key, hath for harmony its own concord; as by demonstration 1.

From the foregoing demonstrations, the bass notes, set to the 8 ascending notes in the treble, will stand thus.

GENERAL RULE. The consecution of 8ths, 5ths, and 4ths, is not allowed, (as by corollary 4.) except by contrary motion of the parts, or in the passage of very quick notes in composition of many parts. No. 32.

From taking in one view the harmony of the seven notes, we shall deduce some useful corollaries. No. 33.

Key 2d, 3d, 4th, 5th, 6th, 7th,
hath the harmony of the
Key 5th, Key 4th, Key and 5th, 4th, 5th,
Semitone. Semitone.

COR. I. Every note in the octave (except the 2d to the key) admits in its harmony a 3d.

COR. II. The key, the 2d and 5th, admit in their harmony a 4th.

SCOLIA.

When the key admits a 4th, the concord is of the 4th. When the 2d admits a 4th, the concord is of the 5th. When the 5th admits a 4th, the concord is of the key. Hence the interval of that note which admits a 4th, is in fact a 5th: therefore two 4ths are no more allowed

in consecution than two 5ths. And hence likewise the interval of the 4th, which we have called an improper concord, appears to be of a middle nature between concord and discord; being a fourth in name and appearance in the natural order of sounds; yet a 5th in name and effect in composition, as member of that chord wherein it makes a part of harmony.

COR. III. The key, the 4th and 5th, admit in their harmony a 5th.

SCHOLIA.

When the key admits a 5th, the concord is that of the key.

When the 4th admits a 5th, the chord is of the 4th.

When the 5th admits a 5th, the concord is of the 5th.

Hence, when a note admits a 5th, the harmony is the concord of the same note.

COR. IV. Every note but the 4th admits a 6th; for, the 4th having its concord for harmony, will have only its 5th.

Every note admits its 8th; for any note may be substituted for its octave. But 8ths are (by corollary 4. of the theory) to be the most sparingly used, as not producing that variety or mixture of sounds requisite to bind the harmony, especially, where it can be best avoided, in the composition of two parts.

From the foregoing demonstrations and corollaries, arise the following observations.

The 3ds and 6ths most frequently occur in composition. This then demonstrates what was asserted, by way of precept, in the 4th corollary of the theory as well as part of the 4th axiom; namely, that the proportions of musical sounds, and the variety emerging from them, point out to us this variety, and will not suffer us to depart from the established precept.

It will be necessary to see the same truths confirmed in the descending notes. We shall therefore set down instances of composition in the descending notes of the octave upon the same principles, and wherein the same demonstrations and corollaries do take place.

Example of composition in the descending notes of the octave. No. 34.

In the ascending notes, when the upper part rises by a semitone, the bass generally falls a 5th; when the upper part falls by a whole tone to a close, the bass also falls a 5th. This fall of the bass, or great cadence, must be effected when chromatic notes are introduced ascending; it being the property of the new semitone, thus formed by the note rising a half tone, to imitate the key or close. By axiom 2. the proportions of sounds, and properties of the same, are deduced from the natural order of the notes. Now, by the new semitone introduced, the note below imitates the greater 7th to the key: therefore, in this case, as in a close on the key, the bass must fall a 5th.

Notwithstanding, this must be understood not of the passage of quick notes; and chiefly at a close.

SECT. 2. *Of Composition in a FLAT KEY.*

FROM the difference between the flat and the sharp key which lies in the different places of the semitone, there will arise a variety in the composition in a flat key,

yet resting on the principles and demonstrations delivered in the last section.

The places of the semitone in the sharp key are the 4th and 8th. In a flat key, the semitone stands in the 3d and 6th places. The variety in the composition will happen where the semitones are concerned. For, as the middle close is made in the sharp key on the 4th, which is the semitone; or, as the 4th in the sharp key hath (by demonstration of the harmony of the 4th) its own concord for harmony: so the middle close in the flat key is made on the 3d, which is the semitone; or the flat 3d will have for harmony its own concord. Now, as the 4th hath its 3d and 5th for harmony, (which are the 6th and 8th of the key;) so the flat 3d will have its 3d and 5th, which are the 5th and 7th of the key.

Again, the flat 7th of the key being the 5th to the 3d, will, like the 5th of the sharp key, have for harmony its own concord. This will cause the 2d of the key to appear as the sharp 7th to the 3d, and the 4th of the key as a 2d (which it really is) to the 3d. Thus the whole harmony will be new modulated by the power of the semitone. Again, the flat 6th being the semitone, a middle close may be made on that note; and then the same proportional variety succeeds, and new harmony, as in the former case.

Lastly, at the end of the musick, where there must of necessity be a close, the flat key will have the greater 7th, like the sharp one. Of so great consequence is the semitone. Nor indeed can a close be made at all, without the passage of a semitone in one or other of the parts. No. 35.

Differences in the flat key noted.

In the first example the harmony of the 2d is the concord of the flat 7th, as being 5th to the 3rd.

The close is made on the 3d, the bass falling a 5th.

The 4th hath its own concord, as in the sharp key.

The 5th standing in an octave, may be understood as part of the harmony of the 3d, as the 3d to the key, in a sharp key.

The 6th is part of the 4th's concord, as in the sharp key; as above in the remark on the 4th.

At the close, there is the sharp 7th, from which the bass makes the great cadence.

In this example there happen four 8ths: the first and last are absolutely necessary to ascertain the key; by the second there is a close made on the 3d; and that on the 5th, is for the sake of the air in the bass.

In the second example, the harmony of the 4th is the concord of the flat 7th, as 5th to the 3d.

The harmony of the flat 6th is its own concord, being the place of the semitone; where the bass rises a 4th (the same as falling a 5th) as on a close in the treble ascending by the semitone.

In the 3d example, these differences of the flat key are left out; and the notes set as if they were part of a sharp key: that is to say, there is no close made on the 3d; the 4th hath its chord for harmony; and the 6th is likewise part of the harmony of the 4th.

For, notwithstanding the propriety of making a close on the 3d and 6th, which are semitones; yet the composer

is not under the necessity of making a clofe in these places in every passage; and then he is at liberty of setting the notes as in the example. This observation clearly points out the difference of composition in a flat key, and where it is to be praftised.

And indeed an author, whose sole end is to please the ear, will designedly introduce a clofe on the flat 3d, and in as many other passages as he can, to create the variety so much desired. In these cases, the rules delivered for composition in the flat key must undoubtedly take place.

The fourth example is set to shew the movement of the bass to the descending notes. The composition is the same as in the other examples.

Let us now take, in one view, the full harmony of every note in the flat key, and where the difference between it and the sharp key lies: from which we may derive some useful corollaries. No. 36.

The harmony of the
2d, 3d, 3d, 4th,
 is the concord of the
Flat 7th, 3d, Flat 6th, Flat 7th.

COR. I. The 2d admits a 3d; then the concord is of the flat 7th.

COR. II. The 3d admits a 5th; the concord is of the 3d.

COR. III. Again, the 3d admits a 4th; then the concord is of the flat 6th.

COR. IV. The 4th admits a 4th and 6th; the concord is the flat 7th.

By comparing these with the corollaries on the sharp key, it will be evident, that each note in the flat key admits for its harmony that note which was excluded in the sharp key. And therefore, that all harmony is divided between the flat and sharp keys; and wonderfully diversified by changing the places of the semitone.

From the demonstration of the harmony of the 5th, with corollary 3. on the sharp key, and the scholium 3. on the same, we gather how great a share of the harmony belongs to the 5th. For it is part of the harmony of the key, and of the 2d (which chord is its own, or that of the 5th) in both flat and sharp key: and, in the flat key, it is likewise in the harmony of the 3d.

The nature and properties of the semitone being the same in both keys, we can now more clearly demonstrate the harmony of it in the following manner.

The harmony of every semitone is the concord of the same.

The key always stands between the greater 7th below, and the whole tone, or 2d, above. Now, by axiom 2. of the theory, the proportions, properties and relations of sounds are deduced from the natural order of the notes ascending and descending: The 4th (in a sharp key,) the flat 3d, and flat 6th, being semitones, are distant by a half tone below, and a whole tone above, as is the key; therefore they have the same properties with the key. But the harmony of the key is the chord of the same: therefore the harmony of the semitone, or 4th, flat 3d, and flat 6th, is the chord of the same. Hence we raise the following axiom.

AXIOM I. The harmony of every member of the concord of the key, is the concord of the key. And the

harmony of every note in the compass of musick, proved by the rules of harmony, is part either of the concord of the key, or of its 5th, or of a semitone. Hence variety in musick is introduced by the contrary motion of the parts, and by changing the key, by bringing in new semitones. The better to illustrate this axiom, we shall hereafter in the examples set harmonical figures over every note, expressive of the chord.

FIRST EXAMPLE.

Let it be required to set a bass to this treble in G sharp. No. 37.

Harmony of the

SECOND EXAMPLE. No. 38.

Harmony of the

THIRD EXAMPLE.

In A flat, No. 39.

FOURTH EXAMPLE.

In G flat, No. 40.

FIFTH EXAMPLE.

In A flat, No. 41.

SIXTH EXAMPLE.

In D sharp, No. 42.

In these examples every passage occurs which hath been delivered in the precepts of composition.

Take notice, that in the last example, the four passages, where the harmonic figures are not set over the notes, are part of a discord; which would take place, if the composition were in three parts; and which we cannot explain till we come to figureate descant.

SECT. 3. Of Composition in THREE PARTS.

THE harmony, or full concord, of every note being well understood, both by reading the foregoing examples, as well as making application of the rules of composition on which the examples are framed, by trial of setting basses to other airs; the next step will be to proceed to composition of three parts.

This requireth no other precept than those already delivered, touching the harmony of each note. For the third part consists of the remaining notes of each concord which have not been made use of in the composition of two parts. Yet this caution must be used, that the two upper parts stand in the nearest concord to each other: that is to say, in 3ds as much as may be, and is consistent with variety and contrary motion of them. For hereby two points will be gained: first, it will bind the harmony; and secondly, the bass, being more at liberty to rise and fall by greater intervals, will meet the upper parts at every point, and produce variety by his contrary motion. The following examples are the same set in two parts above.

PROB. Let it be required to set a bass and second part to this treble. No. 43.

PROB. Let it be required to set the ascending notes of the octave in three parts, in a flat key.

In G flat, No. 44.

In A flat, No. 45.

In G flat, No. 46.

The harmony of the seventh bar in the last example, is altered in the repetition; though the notes of the first treble be the same.

In the first instance, the concords are of the key and 5th. In the repetition, the concords are of the 3d and flat 7th.

In the first instance, the passage from the 5th into the key, (in the 8th bar,) being the great cadence, is just.

But if otherwise a clofe had been made on the 3d, (in the 8th bar,) the harmony in the second instance must, for the same reason, be preferred.

Hence it will be easy to decide in all flat keys, (to which only this case belongs) when the harmony of the 3d is to be part of the concord of the key, and that of the 2d the concord of the 5th; or, when the harmony of the 3d is to be its own concord, and that of the 2d or 4th part of the concord of the flat 7th.

Hence, and from corollary 1. of the theory, and from the demonstration of the harmony of the semitone, we deduce this general theorem.

The truest harmony is produced by the whole concords taken together falling in succession, as frequent as is consistent with the approved rules of harmony, by a 5th.

We shall put an end to composition in three parts, with the following example in a flat key, being one of these above in two parts. No. 47.

The use we shall make of this example is to remark, that although the bass be altered from that which is set in the same example in two parts; yet the harmony is the same, as is evident from the harmonic figures set over each.

Secondly, The 4th having its own concord, passes into the key, or 3d, in the passage of quick notes, and where there is not a clofe. But where, on the 6th bar, a clofe is made on the 3d, the bass making the great cadence, the 4th in the preceding bar is part of the concord of the flat 7th. And thus the whole harmony falls a 5th.

We have altered the bass also to answer the purpose of the movement of the upper parts in the closest harmony. And likewise to prove, that composition of many parts differs from that of two only. A truth which every composer should always have in view. For it will be found, upon trial, that, when the musick is set in two parts, if it be required to add a third, it will not be in the power of the composer to give that third part an air. A matter which ought to be studied by all means; and which, it is evident from the example, can be executed, without injuring the harmony in the least, by composing the three parts together.

We therefore recommend it to the practitioner to make himself perfect in the composition of two parts, before he engages in three; as he will thereby not only sooner become master of the harmony; but also, by discovering more clearly the difference we are pointing out, will execute the composition of three parts with more ease and propriety.

SECT. 4. Composition of FOUR PARTS.

IN composition of 4 parts, every note in the concord is taken; or to every note there is full harmony.

The fourth part, or tenor, now to be added, consists of the remaining note of the concord, which was not used in composition of three. The octave therefore will take place in the concord of every note. The consecution of which, as well as of 5ths and 4ths, is to be avoided between the same parts. The rules already delivered in the composition of three parts must be attended to in this.

Example of the ascending notes of the octave in composition of 4 parts. No. 48.

SECOND EXAMPLE.

In the descending notes of the octave in composition of 4 parts. No. 49.

THIRD EXAMPLE in 4 Parts.

In A flat, No. 50.

FOURTH EXAMPLE in 4 Parts.

In G flat, No. 51.

In composition of 4 parts, it was said, that to every note there is full harmony. Notwithstanding, in the first example, the sixth notes of the first treble and tenor are in unison; each being a 6th to the bass; so that the octave hath no part in that concord. This is done to avoid the consecution of 8ths, by the succeeding note of the tenor, whose place must be, for the air's sake, the 8th to the bass, as well as to bind the harmony.

In the second example, the seventh notes in the first and second trebles are in unison; both being a 5th to the bass. Let not this be understood to be a consecution of 5ths, as they are members of the same chord; but is done for the sake of the air of the second treble. Let this remark serve for every like instance which may happen hereafter.

In the fifth bar of the third example, the second note, the second treble and tenor are in unison. This is done to avoid the consecution of 4ths, which, had the tenor kept his place, would have happened from the foregoing note between the first treble and tenor.

In the same example, there is a consecution of 5ths in the two next bars, by the tenor falling a 4th, and the bass rising a 5th. This seeming error is tolerated, since it is effected by contrary motion of these parts. For as well as it is by the contrary motion of the parts, that the consecution of perfect concords is avoided; so for the same reason, the sameness of the harmony disappears, or escapes the ear; especially in composition of many parts.

By this reason, the consecution of 4ths is prevented by the bass rising a 3d, according to the first observation on this example, at the 5th bar. For that would have happened by all the parts descending; that is, not having contrary motion. The second note then of the bass in that bar is changed from that which is set in the same example in three parts.

A few general remarks occur in this place, from comparing the composition of four parts with that of three.

First, Whereas the perfect concords have place in some part of the harmony of every note in musick of 4 parts; so the chances of the consecution of 8ths and 5ths being more frequent, the more skill and attention will be required to avoid them.

Secondly,

Secondly, Composition of 4 parts differs in many particular passages from that of three, though the general precepts of harmony belong to both. For, by comparing the same example in both cases, there will be seen a variation of some passages in the lower parts. The necessity of complying with the established precept of variety, by preventing the succession of perfect concords, hath caused this alteration. See the 5th bar of the example in A flat in the three different compositions.

Hence arises a new reason for saying the composition of many parts differs from that of few, or two only. Therefore, in whatever number of parts the music is to be composed, one design must be first laid down; and to adjust and perfect the harmony, and to create as much variety as possible, the whole work must be planned at once, and executed agreeable to that design.

Lastly, Of the tenor in particular, we have this to remark, That, whereas in composition of three parts, there is often a liberty left of taking any one of the concordant notes to the bass; in four parts, the fourth or tenor coming in leaves no room for that liberty; but obliges us to a certain disposition of each member of the harmony, and by this means holds together the parts, the octave every where sounding and binding the inner notes together.

This remark on the tenor is more particularly true at almost every close, where the tenor note is the 8th to the bass on the last note but one of the close; and, by keeping its place, while the bass making the great cadence falls a 5th, the same tenor note becomes its 5th. Thus the two concords are held together and entire by the tenor's not removing.

SECT. 5. COMPOSITION OF FIVE PARTS.

THE four concordant notes answering exactly to four parts in composition; when a fifth part is to be added, it is evident one note of the harmony must be repeated in every concord. The fifth part therefore consists of the notes which are by turns repeated in each of the former, in which the avoiding the consecution of the perfect concords is to be observed as before; and the air of this part attended to as far as may be consistent with the rules delivered.

Example of composition of 5 parts in the ascending notes of the octave. N. 52.

Second Example in 5 parts. No. 53.

The two octaves between the tenor and bass on the sixth and seventh notes of this example, are allowed; as the parts do not move into other notes, or make a new concord.

Third Example in 5 parts. No. 54.

The consecution of 5ths between the tenor and bass is admitted, as they meet by contrary motion of the parts.

Fourth Example in 5 parts. No. 55.

It is observable from these examples, that the most difficult composition is that of 4 parts. The other 4 parts, consisting of a repetition of one or more of the concordant notes of the first four parts, are more easily contrived, nothing more being required than to avoid the consecution of the perfect concords between any two parts.

VOL. III. N^o. 82.

SECT. 6. COMPOSITION OF SIX PARTS.

IN music of six parts there is a repetition of two concordant notes. The sixth part therefore consists of the notes which take place in each of the five former, by turns.

An example or two will sufficiently illustrate this.

Example of composition of 6 parts. No. 56.

There is a consecution of 8ths between the fourth line and bass, on the 3d and 4th notes; but it being the effect of contrary motion is admitted.

Second Example in 6 parts. No. 57.

The two 8ths between the tenor and bass are allowed; for, as they do not move, they are in effect but one.

Third Example in 6 parts. No. 58.

The consecution of 8ths is by repetition of the same note, and therefore reckoned as one.

Fourth Example in 6 parts. No. 59.

In the 8th bar there is a consecution of 8ths between the third part and tenor effected by contrary motion of these parts.

SECT. 7. COMPOSITION OF SEVEN PARTS.

IN composition of seven parts, three notes of the harmony are repeated in each concord. The seventh part therefore consists of the notes which are taken by turns from each of the six former; or, which is the same thing, from the first four; under the restriction of the rules concerning the consecution of 8ths, 5ths and 4ths between any two of the parts, unless produced by contrary motion of the same, or repetition of the notes, or in the octave, as said above. The seventh part is written in the tenor cleff, and is a second tenor to the first; so that, like the upper parts, it must stand in the nearest concord to the first tenor, or next part.

First example of composition of 7 parts. No. 60.

Notwithstanding it hath been said, that three notes of the harmony are repeated in each concord in seven parts; yet it doth not appear in every instance in the example. The reasons are, that in every close, whether middle or final, it is preferable that most of the parts should end in the concord note of the close, and especially of the last close, that the harmony of the key may make the deeper impression on the sense.

Secondly, The air of each part should be consulted: for this will not only justify, but demand the changing of one note of the harmony for another.

Again, as the parts next each other should stand in the closest concord; so, in order to effect this sometime by contrary motion, they will meet in unison; and therefore the repetition of the three notes will not take place in every chord.

These rules will be sufficient to answer any doubt, or determine any choice to be made of any note of the concord, as well as justify the meeting of the parts in unison, in music of any number of parts whatever.

Second example in 7 parts. No. 61.

Third example in 7 parts. No. 62.

SECT. 8. COMPOSITION OF EIGHT PARTS.

THE eighth and last part is the second last, i. e. n^o ing

ing which the following rules and observations must be premised.

If the musick be composed for voices and instruments in full choir, it will be elegant and proper that the second bass stand in the nearest concord with the first, after the example of the trebles and tenors.

The reason is, that the two choirs singing either together, or in responses, will thus exhibit greater variety.

After this manner we shall set the two following examples.

If the musick be for instruments only, the difference of the basses consists in two things: First, The organ hath the figures of the thorough bass written. Secondly, The bass viol performs the solo parts, while the organ rests. And in full concert the two basses move in unison. This is the manner in which the basses of instrumental musick are set by the most approved masters.

We shall in this place offer our opinion on the subject of two basses in instrumental musick, relating to some alteration from the usual method of practice described above; which, as being perhaps new, will be received according to the notice it deserves.

We would have the part for the organ move in long notes, and by the least intervals; the figures filling up the harmony and discord; while the part for the violoncello moving in quicker notes, and greater intervals, becomes descant to the other bass. Of this an example shall be given when we come, in the next place, to treat of plain descant.

To return: In musick of 8 parts, the four notes of every chord are repeated, (allowing the exceptions remarked above.) Therefore, the full harmony of every note is double. The due mixture of which, according to the rules delivered, and the contrary motion of the parts, produce all the variety which harmony without discord is capable of affording.

First example of composition of 8 parts. No. 63.

Second example in 8 parts. No. 64.

Having given examples sufficient for instruction in composition of harmony in the several parts of musick, and having illustrated in the same examples what hath been said concerning the harmony proper both to flat and sharp keys; we shall proceed to make such observations on composition in general, as may assist the practitioner in the application of the rules at the beginning, or first attempts.

And first, concerning the consecution of perfects; which must be avoided, except in contrary motion of the parts, or repetition of the concord in the same notes in each part, or in the octave.

Let the intervals which constitute the octave be remembered, as hath been said above (in p. 321.) namely, a 5th and 4th, a 6th and 3d, a 7th and 2d; taking care, that when the note of one part rises or falls by one of these intervals, the note of the other part should not fall or rise by the interval which is the complement of the octave.

Thus the consecution of 8ths will be easily avoided, and much trouble thereby saved in setting the parts.

Again, by the same caution, we avoid the consecution of 5ths. For the notes set in the concord of a 5th, rising and falling together in the different parts, by the

same constituent intervals of the octave, will likewise meet in a 5th; and, by avoiding such movement of the notes of a 4th, the consecution of the same is in the same manner prevented.

One instance of each will shew this evidently. No. 65.

The consecution of perfects, it is true, is tolerated, when effected by contrary motion of the parts. But these observations are made for the sake of a beginner, that he may not too often incur the abuse of this liberty.

The next observation is concerning the harmony of the 4th in a flat key.

The 4th in a flat key is either part of the concord of the flat 7th, or hath for harmony its own chord.

The harmonical figures over the examples point out this to sight. Notwithstanding, it may be asked in what case either harmony is to be preferred.

We shall endeavour to ascertain this matter upon the principles on which what hath been already taught is demonstrated.

In page 430. col. 1. we deduced this general theorem; That the truest harmony is produced by the whole concords taken together, falling in succession, as frequent as is consistent with the approved rules of harmony, by a 5th.

Therefore, when a close is made on the semitone, or flat 3d, the harmony of the 4th or immediately preceding note, must be the concord of the flat 7th. For thus the whole chord, or harmony, according to the foregoing theorem, falls a 5th.

And this theorem extends to the harmony of every note whose interval is a semitone, or which stands a half tone above and a whole tone below its contiguous notes, whose movement into the next chord must be falling a 5th.

The places of the semitone in the harmony of the key, are the key, the flat 3d, the 4th (in a sharp key,) and the flat 6th, and not in the harmony of the key, where-soever a semitone is introduced by the addition of a sharp or flat, whereby a close may be made on the semitone above.

This the truth of the first axiom of the practice is established; where it is said, That the harmony of every note in the compass of musick, proved by the rules of harmony, is part of the concord of the key, or its 5th, or a semitone. For the flat 7th is to the flat 3d a 5th.

In the other case, when a close is not made on the flat 3d, or when the harmony need not fall a 5th, then the 4th may have for harmony its own chord. And here the 4th stands generally in the bass. Thus No. 66.

The proof of this depends on the relative proportion of the flat and sharp keys; and will be given, by that analogy, under the article of transposition.

The last observation is in respect of the practice of authors of instrumental musick, in composition of many parts.

Whereas in the composition of 7 and 8 parts, the harmony of the notes are doubled: this is effected by the common practice, after the most easy manner, by doubling whole parts; that is to say, by two alternate parts moving through every note in unison, when in full concert; and likewise other two alternate parts. Thus the first and third violins play in unison; and the second and

and fourth. And, when these parts are not thus doubled, the third and fourth parts rest. Or otherwise, in some passages they take part of the harmony from the other parts, as in the examples above of 7 and 8 parts; excepting only in longer notes than the upper parts. The concertos of Corelli, Geminiani, and the overtures of Handel, are instances of this.

In a word, whatever form the parts of musick may be disposed in, the principles of harmony are the same.

And when the rules of composition in counterpoint, which is the ground-work, are well understood, and confirmed by practice, the remaining part will become easy in proportion as the composer will find himself more at liberty to dispose of the parts to such advantage as he will judge most suitable to the genius of the musick he is about to compose.

CHAP. II. OF PLAIN DESCANT.

THE second manner of composing is when the succession of concords is by notes of different lengths in the several parts. It differs from counterpoint, not in the principles of harmony, but only in the form.

The effect of descant is variety; which is produced, either when two or more notes of one part are set against one note in another, or when a long passage in one part is set against a single note in the other. This last manner is properly called descanting on that note. Or lastly, When a subject is set in the bass, and constantly repeated; while at every repetition of the same, there is a variation in the treble, which diversifies the harmony, but doth not deviate from the rules of art.

This bass, which is the first written part, is called a ground bass; and the piece of musick is called a ground.

Again, in descanting, it is usual for the parts to relieve each other; the bass sometimes holding the note, while the descant is in the treble; and again, the note is held in the treble, while the descant is in the bass.

The finest descant is where the discords are introduced in the passage of the notes. For here the air is less constrained; and the variety, in respect of the harmony, greater. This is figurate descant, which shall be treated of in the next chapter.

To return to plain descant: The movement of every part is more free than in counterpoint; and not so easy and unconstrained as in figurate descant. From this then arise its chief uses.

In the first place, it is the best introduction to the practitioner, to give an air to every part of his musick: It is also the ground-work of inventing variations in the treble upon a plain subject in the same part. The rules for plain descant are these.

Every note in the descant must be one of the harmony of each note in the bass; as demonstrated in composition in counterpoint.

Secondly, If the descant be variation on a given subject, in the treble, the original air must be preserved as much as possible in imitation of the same.

The harmony then being the same as in counterpoint, the difference being only in the form or length of the notes, one example, after so many given in counter-

point before, will be sufficient to illustrate this part. No. 69.

Whatever the subject of descant may be, whether a ground bass, or air in the treble, (the descant on which is called variations,) the practice is the same; as in the example, where the bass is the ground to the four trebles, the uppermost line of which may be called the air; and the other three descant on the bass; as well as variations on the subject, or first line.

For the more easy execution of both kinds, take these following rules of practice.

If you are to raise descant on a ground bass, then on this supposition the bass is first framed. Next let plain notes in the treble be set, as in the example, though no other use were to be made of them than to guide the composer's eye, and thereby furnish matter more readily for a better air and for the descant.

If the subject be an air in the treble, on which you are to make variations; as, in this case, the air is the first part written, so it is the object on the book to which you are to attend constantly as a pattern for the variations or descant.

It would be advisable also to set a plain bass to the treble or plain song, before you begin the variations. For, as the bass, or second note, in many cases determines the concord of the note; it thereby assists and rules the descant to be raised.

In general, when the two parts are set in plain harmony, the descant ought to imitate, and not depart from that design. If otherwise a discord be introduced in the composition of the two plain parts, or a discordant note be brought in in the treble or air, the descant must take part of the discord,

This properly belongs to figurate descant. Notwithstanding, it is an elegance common in practice, to throw in a discordant note in the variation, which is not in the plain song.

But these rules are addressed only to beginners.

Having done with plain descant, we shall here give an example of what hath been offered (p. 332. col. 1.) relating to the manner in which we would have the two basses set in composition of many parts; which is, That the part for the organ should move in long notes, and by the least intervals; the figures filling up the harmony and discord; while the part for the violoncello, moving by quicker notes, and greater intervals, becomes descant to the other bass.

The manner of setting the two basses depending on the principles of plain descant, and implying nothing more than what is contained in the last example, one instance of this will sufficiently answer our intention here.

Example of two basses in composition of many parts. No. 68.

The variety will be still greater if this manner be pursued in figurate descant. For as undoubtedly that is the best and most perfect composition where discord is intermixed; so there is no variety, which musick is capable of, produced from the form or disposition of the parts, that will not receive improvement from the more perfect composition.

The

The last example therefore, and what hath been said of the two basset in plain descant, is meant as an introduction to a trial of the same in the more perfect, or figurate descant, both in the composition and performance.

CHAP. III. OF FIGURATE DESCANT.

FIGURATE descant is the mixture of discord and concord, by notes of the same or different lengths or time, in the several parts.

Every interval in musick which is not harmony, must be discord.

The discords therefore are six: namely, the lesser and greater 2d; the sharp 4th, or flat 5th; the lesser and greater 7th; and the 9th. The reason for repeating the 9th, which is the 8th to the 2d, shall be shewn in its place.

The use of discord is twofold: To give a better air to every part of the musick; and to create variety. For the discords standing in the natural order of the notes, between the concords, afford an easy passage of the same; and, at the same time, mix with, and bind the harmony.

Discords are introduced in composition several ways.

First, When the notes passing in the natural order, two, three, or more of one part are set against one of another part. This passage of the notes is said to be by diminution; as in the following example.

Example of discords in passage by diminution. No. 69.

When the treble descends, the discords descend likewise into the concords; that is, the 9ths pass into 8ths, the 7ths into 6ths, and so forth. The same thing happens when the bass ascends.

When the treble ascends, or the bass descends, the contrary happens; that is, the 2ds pass into 3ds, and the 7ths into 8ths, or the discords into concords, according to the natural numbers.

When a single discordant note is set, the change of that note into a concord is properly called the passage of the discord.

When the accompaniments are set along with the discordant note; that is, when the whole discord, either in composition of many parts, or in figures in the bass, is expressed, the change of the same into a concord is justly called the resolution of the discord. The passage of the discord in single notes moving according to the natural order, as in the last example, is evident.

The accompaniments and resolution of the whole discord depend on certain principles; on which we shall, in its place, demonstrate the same.

To proceed, then, on single discords.

The second way in which discords are used in composition is, when the notes of each part move alternately, a long note between two short ones, so that the note of one part breaks off and ends in the middle of the note of the other part. This is called syncopation or binding; for the frequent mixture of the discord here supports and binds the harmony;

As in this example. No. 70.

In this manner the air of either part is less constrained, by the constant return of the discord, and passage into the concord. In some places this happens by the natural suc-

cession of the notes by diminution, as in the first example, though not so frequently as in the last manner by syncopation. But there is a passage of the discord into the concord, formed by the notes moving by greater intervals.

This musick is preferable on account of the great variety produced by this unexpected, and, we may say, surprising mixture of the discord and harmony. For variety itself causes new pleasure, when it is least expected, or when attended by novelty.

This moving of the notes by greater intervals, is the third way of introducing discord; and is the effect of the discords and concords constantly meeting by contrary motion of the parts.

In this manner the variety arises from the passage into concords, different from those which must succeed, either in the natural order of the notes, or by syncopation.

The variety also is greater by the constant succession of discord and harmony almost through every note.

For here the composer is at liberty to pass into any concord he pleases; and to resume any discord. For as the passage into the perfect concords, between two parts, cannot be effected, but from the nearest discord, when the notes move in the natural order; so, when the notes move by greater intervals, there is opportunity for many passages, which could not take place in any other way.

All this will be evident, when we come to understand the resolution of the discords.

Example of the more perfect mixture of discord and harmony. No. 71.

In this example are set forth the two first ways of using discords; namely, by diminution and syncopation, as well as passing by greater intervals; being set according to the rules relative to each manner. Where the discord and harmony move by greater intervals, there the passage is from discords new and unpractised in the other two.

The composition, where this liberty is taken, does most justly challenge the name of ornamental or figurate descant.

And the musick, wherein the discord is used these three several ways in their turn, must be esteemed the best, as exhibiting greater variety than could be expressed the other ways only. Let it be remarked in this place, that this new passage of the discord is effected by both parts generally moving by a semitone; the power of which will be seen when we shall have demonstrated the accompaniments and resolutions of the whole discord.

There is a fourth way wherein discords are admitted in composition. This is when discords succeed each other; or, where there is no passage into a concord. This is setting discords note against note. It is to be done two ways. First, when the discord passes into one of another denomination, in the natural order of the notes, by contrary passage of the notes of each part, of the same or nearly equal quantity.

This passage of the discord is necessary, as we cannot ascend or descend by the degrees of a great interval; but the intermediate discords will take place, and thence oftentimes two will succeed each other.

This

This liberty is to be used chiefly in short notes, and by diminution.

Example of discords succeeding each other, or set note against note. No. 72.

Secondly, Discords are admitted, note against note, when the same discord is often repeated. This liberty is taken with the discord of the flat 7th above all others; and is most justly practised in musick of three parts. When this discord is brought in successively in two parts, the complement of the chord ought to be written in the treble.

Example of the discord of the flat 7th successively. No. 73.

This example is taken out of the eleventh sonata of Corelli's fourth opera.

In this example, it is remarkable, that the first and second trebles furnish by turns the discord to the bass; which constantly descends by a 5th, while the intervals of the upper parts are 5ths and 4ths to the bass alternately. Observe, when the note in the bass is flat, the discord will be the sharp 7th.

The imitation of this passage may be learned by inspection of the example. The demonstration depends on the demonstration of the third resolution of the discords following; which we must therefore reserve for that place.

An example of this passage shall be given when we come to teach the use of discords in musick of three parts.

Having done with the single discords and their passages, we proceed, in the next place, to the complex ones; by which are meant the same discords with their accompaniments and resolutions.

Now, as, by axiom the second of the theory, from the natural order of notes, the properties, proportions and relations of sounds, which arise out of their various combinations and successions, are deduced; we shall demonstrate the properties of the discords upon the same principle.

The first property of the discord is the notes which are to be played in the thorough bass, in concert with the discord. These notes are called the accompaniments.

On the exact knowledge of these depends the second property of the discord; namely, its passage into a succeeding concord.

This passage is called the resolution of the discord, as mentioned above.

Each discord hath its own distinct properties. Therefore the definition of discord already given is just; where it is said, that discord consists in certain variable proportions of the distance of sounds,

As two single notes standing at a certain interval, form the discord, so they may easily be resolved into the proper succeeding concord, as we have already shewn.

And on instruments which have not keys, no more than the two notes can well be performed. Yet, as the resolutions of the discords cannot be demonstrated without the knowledge of the accompaniments, we shall consider the whole discord together; and demonstrate the accompaniments of each particular discord, after the same method we have proved the harmony of each note of the octave in counterpoint.

THEOREM. Since every interval in musick is discord or harmony, the accompaniments of most discords will be harmony in themselves: for thus they will be discord to the given note. But it will also happen, that some note of the accompaniment in other cases will also be harmony to the given note, yet the whole accompaniment discord in itself. For the soul so accords with harmony, as not to bear an entire perfect discord.

Now, as more or less of discord with the given note prevails; so the discords are naturally divided into proper and inharmonic.

A proper discord is the concord of some member of itself, and only discord in part with the bass or given note.

An inharmonic discord is an absolute discord in itself, and partly concord to the bass or given note.

There are five proper discords; namely, the lesser and greater 2d, the sharp 4th (or flat 5th), the sharp 7th, and the 9th.

There is one inharmonic discord; which is, the flat 7th. It hath three places in the compass of the octave; where it appears in three different forms.

It is called inharmonic; not only because it is an absolute discord in itself, but also because it is not the accompaniment to the bass note, from whence the order of the discords is traced in the natural series; except in one place or form, which is the second; wherein the flat 7th is the uppermost note of the chord. This will be seen most clearly, when we shall have gone through the discords of each kind in their natural order, in the table of discord and harmony. No. 82.

We proceed therefore to the demonstration of the discords. And, according to the 2d axiom of the theory, shall begin with the demonstration of the accompaniments of the 2d.

As in the demonstration of the concords we begin with the key-note, which we considered as an immoveable point, from whence our calculations were to proceed; so we shall here consider the bass, or lower note of the discord, that immoveable point; and the upper discordant note the interval in question, whose properties are to be found.

Demonstration of the accompaniments of the 2d.

The accompaniments of the 2d are the 4th and 6th to the bass or given note, or the discord of the 2d is the concord of the same.

The 2d is a proper discord: Therefore the accompaniments of the 2d are its 3d and 5th. But the 3d and 5th to the 2d, or discordant note, are to the given note the 4th and 6th; therefore, the accompaniments of the 2d are the 4th and 6th.

Example of the first discord, or discord of the 2d. No. 74.

Proper discord.

The discord of the 2d must be a proper discord: for the 3d and 5th to the bass with the 2d would be intolerable discord, seeing they are three notes in the natural order, and the 5th and 7th is the harmony of the 2d; therefore they must be the 6th and 8th, which is the gi-

ven note : But the 6th will have the 4th ; therefore the discord of the 2d is a proper discord.

By the 2d axiom of the theory, the properties, proportions and relation of sounds are deduced from the natural order of the same. Which axiom is extended to the discords, as they are combined of the natural notes, and differ from the concords only in form.

On this axiom, then, we are to investigate the next succeeding discord. The 2d discord is the 2d, 4th, and sharp 7th to the given note. For these are the next succeeding discordant notes.

Demonstration of the second discord.

The 2d and 4th cannot have the flat 7th ; for they are harmony, or concord of the flat 7th ; and the 8th is the given note : therefore it remains, that the second discord is the 2d, 4th, and sharp 7th to the given note.

Example of the second discord. No. 75.

Inharmonic discord.

This is an inharmonic discord ; being an absolute discord in itself. It hath but one concurring note with the bass ; which is the 4th. This 4th is the flat 7th to the given note's 5th : which 5th is the bass to this discord ; the given note in this place being considered only as a point, or unity, from which we are to investigate the next discordant notes, according to the 2d axiom.

The property of this inharmonic discord, or flat 7th, is, that its own discordant interval, or that which is formed by the accompaniment, is always a sharp 4th, or flat 5th, which distinguishes it at sight from every other discord. And every inharmonic, where-ever found, hath the same property. The resolution also of every inharmonic is the same ; as we shall see, when we come, in the next place, to shew the resolutions of the discords.

The next discord, according to the 2d axiom, is the sharp 3d, 5th, and flat 7th to the given note. This is also an inharmonic, or flat 7th ; and having the same property with the former, namely, the flat 5th, must not be accounted a new discord. No. 76.

Inharmonic discord.

This is the inharmonic discord in that form, whose accompaniments are relative to the bass, or given note.

The third discord is the 3d, 5th, and sharp 7th to the bass, or given note.

Demonstration of the third discord.

The sharp 3d, 5th, and sharp 7th, must constitute the next discord. For the flat 3d, 5th, and flat 7th, are harmony, or concord of the flat 3d ; and the 8th with the 3d and 5th, are the chord of the bass note ; and the flat 7th, with the sharp 3d and 5th, are the inharmonic last mentioned : therefore, the sharp 3d, 5th, and sharp 7th, are the 3d discord.

Example of the third discord. No. 77.

Proper discord.

This is a proper discord, being the concord of the 3d to the bass, and the sharp 7th to the discordant note.

To proceed then according to our 2d axiom, the next

discordant notes in order, are the 4th, 6th, and 8th : But these being the notes which constitute the first discord, varying only in place and name of the 9th, for the 2d, are in effect the same discord.

The next successive discordant notes are, according to our well known axiom, the 4th, sharp 7th, and 9th. But these likewise constitute the 2d discord in like manner, as was said in the former case ; and therefore cannot be reckoned a new discord.

To proceed then by our axiom : The next ascending notes, by the smallest intervals, are the sharp 4th, 6th, and 8th. This is an inharmonic, or flat 7th ; its flat 5th being formed by the sharp 4th and 8th ; therefore no new discord. No. 78.

To go on, the next discordant notes will be found the sharp 4th, 6th, and 9th.

Demonstration of the fourth discord.

From the proof of the last inharmonic discord, the sharp 4th and 6th can form a proper discord with no other interval but the 9th ; for the 7th would produce three notes in the natural order, and intolerable discord. Therefore the fourth discord is the sharp 4th, 6th, and 9th.

Example of the fourth discord. No. 79.

This is a proper discord, being a concord in itself, and only discordant to the bass note. The discordant notes of it are the sharp 4th and 9th.

The next which presents itself, is the 5th, sharp 7th, and 9th, by the same axiom.

Demonstration of the fifth discord.

The 5th will admit no other discordant notes but the sharp 7th and 9th. For the 8th and 10th make the concord of the bass note ; and the sharp 7th and 10th is, with the 5th, the third discord already proved ; and any other note would be double discordant, and intolerable : therefore, the fifth discord is the 5th, sharp 7th, and 9th.

Example of the fifth discord. No. 80.

Proper discord.

This is a proper discord, being a concord in itself ; and discordant only with the given note. Its discordant notes are the 7th and 9th.

We have purposely reserved the discord of the lesser 2d to the sixth and last place, 1st, Because, as the interval next above the key is always a whole tone, we cannot, according to our 2d axiom, erect this discord as relative to the given note, or key ; as we have done the other five. 2dly, The resolution of this discord will be found different from that of the greater second ; for reasons which will abundantly appear, when we speak of the resolutions. This discord may properly be called the discord of the semitone.

Demonstration of the discord of the semitone.

The discord of the semitone, or lesser 2d, is, like that of the greater 2d, or whole tone, the 2d, 4th, and 6th. The demonstration is the same as that of the greater 2d, and therefore need not be repeated here.

Example of the sixth discord. No. 81.

This is a proper discord, like that of the greater 2d, being

being a concord id itself. Its note discordant with the bass is the 2d.

It hath been said, that all harmony is divided between the flat and sharp keys.

The mixture of discord and harmony enables us to extend the like observation in this place much further.

Hence the following corollary.

The composition of all musick, of any number of parts whatever, is divided between the harmony of the flat and sharp keys, and the just mixture of discord with it.

To illustrate these truths, we shall set in one view every concord and discord, in the whole compass of musick, in their natural order. No. 82.

Hence we shall derive some useful corollaries, which will lead us to discover what is next to be considered, the second property of the discords, or their resolutions into the concords.

The manner of reading this is as follows :

This concord is the concord of the key.

This concord is the concord of the 2d to the key, or given note.

This concord is the concord of the flat 7th.

This discord is inharmonic, and so forth : descending still from the uppermost lines of harmony, or discord, to the lowest line, or bass.

In this view is seen the mixture of discord with harmony, each in the natural order. Wherein, indeed, nothing regular or proportioned appears to sight. The reason of this is, evident from the demonstration of the harmonical proportions. For, if they be of a species different from all other proportions, as by corollary 2d of the theory, and must be demonstrated on principles peculiar to them; then the succession of the discords, constantly taking place between the intervals of harmony, must be disproportioned too. This appears to sight in the next example, or view of harmony and discord in the natural order. No. 82.

However irregular this may seem, an uniformity prevails through the whole, which supports that variety in musick so desirable: Without which variety, there could have been but one concord among sounds; a sameness prevailing through the whole; without semitone, and consequently without discord. In this case, musick never could have existed as an object of pleasure to the sense; much less of science.

This admirable structure is raised on the power and property of the semitone, which shall be the subject of the following corollaries.

COR. I. Every semitone in the octave hath either a concord or discord proper and peculiar to itself. Yet, the natural succession of the concords and discords is not according to the ascending and descending semitones. For, it is evident, in the annexed table, that the corresponding bass notes constantly descend by 3ds, the variety, at the same time, shining throughout the harmony and discord in the upper parts, ascending by semitones. Yet the bass expresses every semitone in its passage by 3ds, uniformly to its period.

This most strongly illustrates the truth of the 4th axiom of the theory; namely, that the concords and discords,

either in their natural order, or arranged by art, will not suffer us to depart from the established precept of variety amidst uniformity.

The same uniformity, or rather unity, is exhibited still more plainly in the 5th discord, in the coincidence of discord and harmony in the same individual sounds.

For this discord, which is the discord of the 5th, is also the harmony of the 5th.

This is truly admirable, and furnishes us with the most interesting remark in the compass of musick, as in the following corollary.

COR. II. The scope of musick, and motion of the parts, must at length terminate, and meet in one invariable thing HARMONY.

Thus are we arrived at the full extent, or bounds of musick. It is fit we now return to make such further observations as will lead us to the knowledge of the resolutions of the discords, which is the next thing to be spoken to.

The division of discords into proper and inharmonic, we have made for the sake of clearness and method. The difference already pointed out between the discords must be remembered; which is, that the property of the inharmonic, or flat 7th, (which note does ever, with another note of the chord, frame the sharp 4th, or flat 5th) is the same, in whatever place or form it is met with; whereas the proper discords essentially differ from each other, and in every particular.

The three inharmonic therefore, in the natural order of the discords, are not so properly three, as the same discord in different light; where it is a preparation for a close on the key, and on the 4th and 5th to the key.

The bass to the discords moves by 3ds descending in a sharp key.

The notes of the bass, corresponding to the proportions of the flat key, have no relation to the discords in the line next above; but are the bass to the concords in the flat key, as demonstrated in the rules of harmony.

The two discords, which are a repetition of the first and second, are set down in compliance with the 2d axiom, to pursue the natural order. And hence they serve to demonstrate there can be no other discord than those exemplified in the scheme. For there is no semitone in the octave which doth not appear there to have its discord or harmony connected with it.

In this scheme then is comprised every interval of musick, with the members of each chord respectively, both discord and harmony, in the natural order.

From the same order, we shall demonstrate the passage of the discords, into the concords or resolutions of the same.

In the theory, it hath been said, that the semitone is the principle, or hinge, on which turns the resolution of every discord.

On this principle, then, we shall now demonstrate the same.

The discords stand in the natural order between the concords; but every note of the chord is not equally near respectively.

From the idea of harmony, which is fitness or propor-

tion.

tion, the passage of the discord must be to the nearest concord; therefore, the resolution will be by the smallest interval, that is, by the semitone.

This is the general theorem for the resolution of every discord. We will now apply it,

The resolution of the discord of the 2d is into the concord of the given note.

The 4th, or semitone, will move into the 3d, but the 3d will have for harmony its 3d; therefore, the 6th must descend into the 5th, and the 2d's passage by the nearest interval will be into the given note. By these passages is formed the chord of the same; therefore, the resolution of the discord of the 2d is into the concord of the given note.

In a flat key, there are two passages by semitones; that of the flat 6th into the 5th, and of the 2d ascending, by contrary motion, into the 3d.

Example of the resolution of the discord of the 2d, or first discord. No. 83.

Proper discord.

The resolution of this discord being into the given note, the bass does not move.

The resolution of the second discord is into the concord of the given note.

The second discord is the 2d, 4th, and sharp 7th. The sharp 7th and 4th move by the semitones and contrary motion into the 8th and 3d, while the 2d falls a 5th into the 5th. These are the concord of the given note; therefore the resolution of this discord is into the concord of the given note.

Example of the resolution of the second discord being inharmonic. No. 84.

Inharmonic discord.

The resolution of this discord being into the concord of the given note, the bass ascends by a semitone.

The passage of this inharmonic by contrary motion of two semitones, and the other note falling a 5th, is the resolution of every inharmonic, where-ever introduced. This therefore needs no repetition. But if the succeeding concord has a flat 3d, the passage is by two ascending semitones; the 2d rising into the 3d, the 7th into the 8th, and the 4th by a whole tone into the 5th. This movement can only happen in the resolution into the key.

The other, of much more extensive use, is the true resolution of the inharmonic discord; and more interesting, as, by its contrary motion of the semitones, it better binds the harmony.

It is necessary here to explain further the nature of the inharmonic discord.

The inharmonic discord, then, is always the chord in a sharp 3d, with a flat 7th; which two notes frame the interval which characterises this chord, namely, the sharp 4th, or flat 5th: when the flat 7th is the upper note of the two, the interval is the flat 5th; when the sharp 3d is the upper note, the same interval is called the sharp 4th. These notes being relative to the fundamental note either of them determine the chord.

As the inharmonic is found in different places of the octave, so consequently the note of the chord must vary accordingly; the second inharmonic therefore only, in the

natural order, hath reference to the given note in the table, as that happens to be the note of the chord. For the given note there is to be accounted only a point or unity, from whence we proceeded to trace the discords in their natural order, as they lie between the concords. The chord note, therefore, of the first inharmonic is the 5th to the given note; and of the last inharmonic, it is the 2d to the same. Now, as the whole chord falls a 5th in the resolution, so the first is a preparation for a close on the key, the second for a close on the 4th, and the last for a close on the 5th; now, as any note of the chord may stand in the bass, so the third is often preferred before the chord note, for the sake of the movement of the bass by a semitone, as well as because falling a 5th in the bass is more properly the part of harmony.

The flat 7th is likewise chosen for the bass note; for the same reason, the movement of the bass by a semitone descending; which is no inconsiderable use of discords. For in figure descant, as we have said, all the parts move more freely.

The next discord is likewise inharmonic. It is the sharp 3d, 5th, and flat 7th to the given note; which note is likewise that of the chord. No. 85.

Note, the resolution of every inharmonic being into its 5th below the chord, the resolution of this will be into the 4th of the given note; as rising a 4th, and falling a 5th, answers the same thing in estimating the intervals of harmony.

Inharmonic discord.

Example of the second inharmonic discord and its resolution: here the bass note is the note of the chord; therefore, in the resolution it falls a 5th, which is the 4th to the given note.

The flat 7th descends by a semitone into the 3d, the 3d rises by a semitone into the 8th, and the 5th falls a 5th into the 5th of the concord. The resolution therefore is into the 4th of the key.

This is that form of the inharmonic discord on which the composition of the passage taken out of Corelli, (No. 73.) is grounded. Observe, that in the cited passage, and also in every like passage, the two notes of the bass move to only one note of the second part, which becomes the flat 7th by this movement of the bass.

Thus the flat 7th is given, in the upper parts by turns, to every note in the bass, as hath been before remarked.

Resolution of the third discord.

The third discord is the 3d, 5th, and sharp 7th, to the given note; it is resolved into the 6th to the same. For the 7th ascends into the 8th or 6th's 3d, the 5th rises a whole tone into the 6th, and the 3d not moving becomes the 5th. The resolution of this discord therefore is into the chord of the 6th.

Example of the resolution of the third discord. No. 86.

Proper discord.

This is a proper discord; in the resolution of which the bass falls a 3d, while the whole discord falls a fifth.

The

The next discord is the sharp 4th, 6th, and 8th. It is inharmonic. Its resolution is into the chord of the given note's 5th. No. 87.

Resolution of the third inharmonic discord.

Of this discord the bass note is the flat 7th; it descends by a semitone, while the whole chord falls a 5th.

Inharmonic discord.

Its resolution is the same as that of every inharmonic, in what form soever, by the contrary motion of the two semitones, while the third note falls a 5th.

Resolution of the fourth discord.

The fourth discord is the sharp 4th, 6th, and 9th. Its resolution is likewise into the chord of the note's 5th.

For the sharp 4th ascends into the succeeding concord's 8th, the 6th passes into the 3d, and the 9th not moving becomes the 5th. Those are the chord of the note's 5th.

Example of the resolution of the fourth discord. No. 88.

Proper discord.

This discord is a mixture of the proper and inharmonic. It is a proper discord, for that the notes of the treble are concord; and inharmonic, in respect of the bass, with which it makes the discord of the sharp 4th.

It differs from the foregoing, where the flat 7th is expressed in both treble and bass; whereas, in this, it is only in the bass.

The bass here also descends by a semitone, while the chord falls a 5th.

Resolution of the fifth discord.

The fifth discord is the 5th, sharp 7th, and 9th. It is resolved into the concord of the bass note.

For the 5th is that note's 5th; the sharp 7th ascends by a semitone into the 8th; and the 9th (or 2d) passes into the 3d. Thus it is resolved into the chord of the given, or bass note.

Example of the resolution of the fifth discord. No. 89.

Proper discord.

In this resolution the whole chord falls a 5th, while the bass stands still, or descends into the octave.

This is plainly the last discord in the order of sounds. Its resolution is into the given note or key, by the passage of the great cadence, or descent by a 5th. It is a concord in itself; and is in harmony the concord of the 5th.

In this chord discord and harmony are united. When it stands in discord with the bass, the bass doth not move in the resolution; when it sounds perfect harmony with the bass, then the bass descends a 5th.

Therefore we conclude, Harmony and discord are like two finite lines, whose beginnings are at a certain distance; and in the natural progression converge constantly, until they meet in a point.

The discord, which we have referred to the sixth place, is that of the lesser 2d, or semitone.

Its places in a flat key are the 3d and 6th; and in a

sharp key the 4th and 8th, or where-ever a new semitone is introduced.

It is a proper discord, being a concord in itself, whose chord hath always a sharp 3d.

Its properties are everywhere alike; but its resolution differs from that of the greater 2d, for the reason assigned in the resolution of every discord; that is, the passage by the semitone.

Resolution of the lesser 2d, or semitone.

The discord of the lesser 2d is the 2d, 4th, and 6th to the bass; or, the concord of itself.

Its resolution is into the concord of its own 3d or 5th. It rises into the concord of its 3d by the single passage of the semitone descending. And into the concord of its 5th by the 4th descending along with the semitone.

Example of the resolution of the discord of the semitone. No. 90.

In the first resolution, the chord rises a 3d, and the bass falls a 5th. In the second, the chord rises a 5th, and the bass falls a 3d, the reverse of the former.

From the resolutions of the discords we derive the following corollaries.

COR. I. There is no interval of harmony that is performed by the bass in the resolution of one discord or another.

Hence we may conceive that harmony regulates even the discords, and presides in every part of music.

COR. II. The inharmonic discord, or flat 7th, is a preparation to a close on a key, the 4th and 5th, flat 3d and flat 6th; for into the harmony of these it is resolved; they being the intervals on which closes may be made according to the established rules of melody. And universally, wheresoever a close may be made by introducing a new semitone, the preparation may be made by the flat 7th, or inharmonic discord.

This discord, being of such extensive use, will deserve some further remarks, which may render the setting of the same more easy, and assist the performer in the taking and resolution of it.

In the inharmonic discord, then, are three notes chiefly concerned, which are the note of the concord; its 3d, (which is always sharp;) and the flat 7th: either of these may be set in the bass. Hence there will arise three varieties.

If the note of the chord be the bass note, the figure is the flat 7th; the chord is that of the same note; and the bass falls a 5th.

Secondly, When the 3d is the bass note, the figures are flat 5th and 6th; the chord is that of the 6th to the same 3d; and the bass ascends by a semitone.

Thirdly, If the flat 7th stand in the bass, the figures are the sharp 4th, 6th, and 9th; the chord is that of the 2d to the bass note; and the bass descends by a semitone.

Example. No. 91.

The 5th of the chord may likewise stand in the bass; but as the movement of the same is by a whole tone descending, it is very seldom used.

The figures are sharp 6th.
flat 3d.

4 Q

†

COR.

COR. III. Hence the bass ascending or descending by a semitone, furnishes an opportunity of introducing notes in the upper parts, which will constitute the inharmonic discord.

And again, the sharp 3d of any chord in the treble, or any note having the addition of a sharp, and thereby becoming the greater 7th, may be the 3d of an inharmonic; the bass taking the flat 7th. For the sharp 3d of the chord, (which is the sharp 4th to the flat 7th in the bass, or elsewhere,) and the flat 7th, in whatever part they are set, in bass or treble, or both in the treble, constantly move each his own way; the first ascending, and the latter descending by a semitone.

These are the simple discords as they are found to lie in the natural order of sounds between the concords; whose accompaniments are, for the most part, harmony among themselves. It is evident, from the method in which we traced them, that there is no other discord among sounds. Notwithstanding, from the combination of two simple discords, a new form of discord may be framed, which taketh part of the inharmonic and discord of the semitone; which, therefore, we call the compound discord.

This discord is the sharp 3d, flat 7th, and flat 2d, or semitone to any note whose chord hath a sharp 3d.

It is resolved, by the passage of three semitones, two descending, and one ascending, into any concord with a sharp 3d; and therefore may be introduced as a preparation to any concord, in either flat or sharp key, where the greater 3d is.

Example of the compound discord, and its resolution. No. 92.

The resolution of this discord, as it is compounded of the discords of the flat 7th, and semitone, will partake of the resolution of the same. Thus the upper note, or semitone, descends into the 5th of the concord; and the flat 7th and 3d meet by contrary passage of a semitone each into the 3d and 8th part of the resolution of every inharmonic, while the bass descends a 5th. Thus the passage into every note of the concord is by a semitone; so great a favourite of nature is the semitone.

By changing the form of this discord, it will be resolved into a chord with a flat 3d, by one semitone descending, and two ascending; the two extreme notes of which are the same as in the example above; but the middle note is the 5th ascending into the 3d, instead of the flat 7th descending. The upper notes therefore form the flat 5th, or inharmonic interval. No. 93.

The properties of those discords, and of the inharmonic, furnish us with some practical observations; which are, that the two discordant notes of these discords are, in music of two parts, a preparation to, or pass by contrary motion of the semitones into the concords of the sharp 3d, flat 6th, and 5th. When the flat 7th is the uppermost note, and the lower the sharp 3d, they pass into a sharp 3d.

When the upper note is the sharp 3d, and the flat 7th is below, they pass into the flat 6th; so do likewise the flat 7th above, and the chord note below.

Lastly, the two extreme notes of the compound discord pass into the concord of the 5th.

Example of the passage of discords in music of two parts. No. 94.

In like manner there is a passage into the octave from a discordant interval; the upper note of which is part of a concord, and the lower the semitone of the compound discord. No. 95. Or the contrary.

There is no passage by two semitones into the flat 3d and sharp 6th from any discordant interval, except the semitone. For, in the passage of quick notes encountering each other by contrary motion, this, or any other discordant interval, may fall into the concords. But such, being tolerated only for their quickness, need not be reduced, as indeed they cannot, to any rules of art.

Lastly, the bass will admit two notes together, each concurring with it, namely, the 5th and 6th, and making a discord between themselves.

This discord, which differs from the proper and inharmonic, is rightly called the mixed discord; each of the two notes being in harmony with the bass, and discordant to each other.

The framing of this discord depends upon the rules of harmony, and may be set to any note of the bass which hath for harmony its own concord, and is likewise the member of another.

Therefore, in the sharp key, the key and 5th, and in the flat key, the key 3d, 5th, and flat 7th, admit a 5th and 6th.

When we shall have proved, under the article of transposition, the 4th in a flat key, and 6th in a sharp key, to have their own concord; they will be found, no doubt, to have the privilege of admitting a 5th and 6th.

For thus it is understood. The key hath a 5th in its own right, and a 6th as member of the 4th.

The 5th hath a 5th in its own right, and a 6th as member of the key.

The flat 3d hath a 5th in his own right, and a 6th as member of the key.

The flat 7th hath a 5th in his own right, and a 6th as member of the 3d.

Thus the 5th and 6th will stand together to the bass. The properties of sounds in the natural order may be transferred by art, and improved into all the variety possible; as this is no other than an imitation of nature.

Hence we infer, that every note, which assumes the nature of the key, by the addition of the greater 7th, will admit a 5th and 6th.

This 5th is easily distinguished from the 5th of the inharmonic, which is always an imperfect one, and ought constantly to have a flat prefixed.

Now the chord of the inharmonic with a flat 5th is that of the 6th to the bass note, as hath been said. But the chord of the mixed discord may be better understood to be the chord of the bass note, with a 6th added.

SECT. 2. OF FIGURING THE BASS.

HAVING delivered all that hath fallen under our observation concerning the nature, proportion, and use of discord; we shall now make an application of the same, in order to explain the figuring of the bass; the next article proposed to be spoken to.

First, Of figuring the concords.

THE

That the notes whose harmony is their own chords; need no figures, is evident from the definition of harmony; which consists of one certain, invariable proportion of sounds.

These are the key, flat 3d, 4th of a sharp key, 5th, flat 6th, flat 7th.

They which, as members of other chords, require the figures of harmony set over them, are these following; and are reduced to this general rule:

The 3d of every concord hath a $\frac{6}{7}$; and the 5th of every concord hath a $\frac{4}{5}$.

Therefore,		And these,
Key		Key 2d
Flat 3d and sharp	} have a $\frac{6}{7}$	Flat 3d and sharp
5th of a flat key		4th of a flat key
Flat 6th and sharp		5th of a sharp key
Sharp 7th		Flat 7th

Lastly, The 4th in a flat key, when it has its own chord, must have a 5th set over it, to distinguish the chord from that of the flat 7th. And the 6th in the sharp key, when it hath its own chord, must have a 5th likewise set over it, to distinguish the chord from that of the 4th.

The proof of the 6th in a sharp key, having for harmony its own concord, depends on the relative proportion of the flat and sharp keys; as will be shewn in the chapter on transposition. So much for figuring the bass in concords.

Let us now inquire into the shortest and clearest method of figuring the discords. This will be no difficult matter, when we consider well the whole discords, as they are full figured in every example.

There the figures set over the bass express the intervals which the notes in the upper parts form with them. These taken together make the whole discord. And as these, with the harmonic chords in succession, express the whole composition, they are therefore called the thorough-bass.

To render the performance of the thorough-bass easy and expeditious being the chief intention of figuring the bass; this will be best answered by distinguishing the discords, which have some figures in common with each other, by such figures only as will strongly mark each discord. For though all the figures set down in the examples be necessary to demonstrate the properties of the discords, and truth of the composition; the case is quite otherwise in respect to the sight; many marks causing perplexity and confusion, when one single mark in this, as in all other cases, best discovers the difference. The proper discords then being concords in themselves, the figure, or figures, discording with the bass note, will distinguish each of these.

The inharmonic discords being the same in different form, will be distinguished by the discording figures peculiar to each form.

Of the properties of this discord, and manner of taking the same, we have spoken sufficiently. We shall therefore only set down the discording figures of each form, in the following example.

Example of the proper discords figured for taking the same at sight. No. 96.

The inharmonic discords figured for taking the same at sight. No. 97.

Moreover, the proper discords bring concords, each in itself; every discord will be concord to some note different from the bass, or discordant note.

To remember this note will render the taking of this discord ready at sight, it appearing in this light a chord of harmony.

The same is in some measure true of the inharmonic discord.

Therefore the figures in the examples, under the bass lines, express the names of these concords relative to each.

It remains to be observed, that the accompaniments of the 2d are the 2, and of the 9th the sharp 7, as they appear in the natural order of the proportion of the same, (No. 82.) It will be necessary to demonstrate here the truth of this.

The 4th and 6th being the accompaniments of the 2d, the fifth and sharp 7th are the accompaniments of the 9th.

For the proportion of the 9th to the 2d (whose 8th it is) is 2 to 1. And the proportion of the 4th and 6th $\frac{1}{2}$. Therefore, by the rule of proportion, say,

$$\text{as } 1 : \frac{1}{2} :: 2 : \frac{3}{2}$$

but the 4th number, or $\frac{1}{2}$, is the proportion of the 5th and sharp 7th; (for $\frac{1}{2}$ give $\frac{1}{2}$;) therefore the 5th, and sharp 7th, are the accompaniments of the 9th. Q. E. D.

The last use we shall mention of the discord is the furnishing the inward parts of musick, in composition of many parts.

As, in harmony, each part of the four takes one of the concurring notes, and hence, by the continual mixture of these by their contrary motion, the composition is framed; so, in figure descant, the notes of the discord furnish the parts in their turn.

And the same notes, passing by semitones chiefly, form among themselves that resolution which the bass performs alone.

The composer therefore, when, setting a bass, he introduces a discord, is as well prepared for the notes of the other parts in this case as in setting a concord; and if he be well skilled in the resolutions, will with great ease compose the succeeding concord.

For the thorough bass, being the whole composition in one view, the knowledge of the one and of the other must be the same. As, then, he who understands the rules of harmony and the discords, and their resolutions, will succeed with ease in composition; so, on the other hand, he cannot be a skilful composer who is ignorant of the properties of harmonical chords and discords.

One example in three parts, being the same set above in two, will sufficiently illustrate this.

Example of the use of discord in the composition of many parts. No. 98.

CHAP. IV. OF MELODY.

HITHERTO we have considered musick in its several parts taken together, or the art of composition. Our next business will be inquire into the method of framing a single part, or making the melody.

MELODY

MELODY is the air of the uppermost or first part in musick, commonly called the tune.

In a plain song, the air is formed without considering the relation which the other parts, which may be set in composition with it, may bear. For, being first framed, and for the sole end of pleasing the ear and fancy; it must, it is evident, be independent of them.

For as to framing the bass first, and setting the treble to it, there appears no necessity either in reason or the rules of composition; they equally serving the purpose of beginning with any part, no part being privileged with any particular member of discord or harmony; as is abundantly manifest from the various positions which the discordant notes have been shewn to stand in; as well as from the 4th axiom of the theory, which establishes variety for conducting and rendering even harmony acceptable; a sameness in the successive concords being the only thing exceptionable in that part of composition.

All the parts of musick then being equally concerned in the composition; to prefer any one part, as a basis, or unerring guide, on which to erect the musick, or bring in the parts, is doing injury to that liberty which nature and the rules of art put us in possession of.

But the air of the first part so essential to the tune, or rather the tune itself, compels us to decide in favour of framing the treble first. In which it will be found impossible to succeed, when it is confined to what the bass, if it be first framed, must of necessity prescribe.

This preference in framing the treble first, chiefly respects a plain song, or air. For, in more elaborate pieces, where the design of the author is imitation of passages in the several parts by turns, according to his choice or fancy making use of the same liberty, he will take any for the leading part, and accordingly write the passage in that part, and finish the composition in the rest.

The air or first part in instrumental musick is called the first treble; the air for a single voice is called the voice part, or song; and in musick for many voices, the upper part is called the counter-tenor.

In this musick, the air of the tenor, and of every part performed by the voice, is studied with more exactness than the inward parts of instrumental musick.

The reason for this difference is, that in instrumental musick, the first violin generally presides, or leads the musick by its air: as this is the composer's design, the other parts must of necessity be accommodated to it.

Whereas in musick for voices, every voice repeating the same words, that is, expressing the same sense, at the same time, or immediately succeeding; nothing can defeat the end of the musick so much, which is the setting of words, or rather sentiments, to notes as expressive of the sense as inarticulate sounds can possibly do, as for one part to excel the others so much in this necessary point, as by comparison to depreciate, weaken, or alter the sense in the others.

The air, therefore, of every part in vocal musick must be consulted; not only for the sake of harmony, (for a good air in each part improves even the harmony;) but also for the sentiment sake, without which the musick must be absurd and dissonant.

Notwithstanding the liberty which every one may justly challenge of framing an air agreeable to his own fancy; yet it cannot be said, that this liberty is uncontrollable, or beyond the power of art to prescribe bounds to: For then indeed every strain composed by even a bad and injudicious ear might stand in competition with the most finished pieces. But as this will not be allowed on any hand, even an undistinguishing ear conceiving a degree of pleasure in hearing good musick; so there is no doubt but that there must be some precept or manner found out by experience, to ascertain and conduct the air or strain, and which will render it to a good and judicious ear plainly preferable.

The rules therefore which we shall lay down for melody, are such only as are founded in truth and reason; the result of experience, joined to skill; and which are admitted in every liberal art: These are unity, imitation, and order. If it shall be said, that persons unskilled in musick, but otherwise very capable from a natural good ear, will sing an air which an artist cannot find fault with, we confess it may be in some sort true.

But the strains of such composers are always very short; and as they seldom or never depart from the key, so they afford not that variety so desirable in musick: Nay, what is this but saying that the rules of art are conclusions taken from nature, as in truth they are; so then they must be assuredly right? This must be so, when the appeal is made from art to nature.

As to those essays called voluntaries, there was never a good one performed but by a good master. The musick was always good in proportion to the master's skill in the art; in proportion to the variety he introduced according to the rules of art. Therefore even voluntaries are the effects of knowledge and deliberation.

But to return. The first rule of melody is unity.

The unity of tune is said to be in respect of the key, and of the subject.

Every tune must be written in some key, in which it must begin and end.

As every air is said to be in such a key as is the last note, especially the last note of the bass; so there is the same necessity for the first and last note of every air to be some member of the concord of the key. This discovers the design of the author. Having thus fixed the attention of the hearer to this particular, the ear and imagination can no other way be satisfied than by holding to and executing the same design.

The unity of tune is as necessary in this respect, as consistency in the words and sentiments of an orator is requisite to discover the scope and meaning of his discourse.

Secondly, the unity of tune, in respect of the subject, signifies, that there should be one subject of every piece of musick repeated and insisted on, as often as conveniently can be, throughout the whole piece.

And this repetition will be in proportion to the length of the tune, and design of the composer. Even in a minuet, or any other exact piece confined to a certain number of bars, the repetition of the subject may be effected. Now, the subject of every air, or piece of musick, is the first passage of the same, for any number of bars,

bars, be they more or less, as it shall happen; every tune being stamped with some prevailing idea or fancy peculiar to itself, and therefore distinguishing it from every other.

The subjects of grand pieces of instrumental musick are contrived with care and study; and invented with design to enlarge or descant upon at will; not being confined to any length, or certain number of bars. Such pieces, being the efforts of great and masterly genius, afford all the pleasure that design and invention, carried on by every masterly stroke of art, can give.

The second rule of melody is imitation. As in the executing other arts, a similitude and proportion of the members ought to be preserved; so imitation, or a repetition of the most striking passages, answers to this in musick.

Imitation may be performed many ways. First, when the repetition of the passage is made, beginning on the note above the leading note of the passage; or on the third, fifth, eighth, or any other interval.

A passage also may be imitated in any of the descending notes. A repetition on the octave below is frequent in every good author.

In the repetition of passages, there are two varieties.

The first is, when the passage is repeated in notes belonging to the harmony of the key. It will seldom happen in this case, that the passage will in the repetition be precisely the same, in respect of the intervals of the notes, though the movement be an exact imitation.

The reason of this will be evident, if we consider that the intervals in both flat and sharp keys respectively ascend by different degrees; the semitone changing the intervals almost continually.

See example, No. 12. in the theory.

In these examples no more than two flat or sharp thirds succeed each other. And where they do succeed, the semitone is in a different place in the two like intervals of flat thirds; it being the third of one interval, and 2d of the next ascending 3d, or the contrary.

In the sharp key, two sharp 3ds ascend from the 4th and 5th, and in the flat key from the 6th and 7th. The inequality of the flat 3ds, and of the few instances of their succession, is owing to the places of the semitone.

To the inequality of the 3ds is owing the inequality of the 4ths, 5ths, and every other unequal interval in the course of the notes; the greater necessarily partaking of the inequality of the lesser, which is included in it. All this is evident.

Therefore, the repetition of a passage will not be precisely as the passage, except in the places abovementioned; that is to say, a repetition of sharp thirds from the 4th and 5th of the sharp key; and of the same, on the 6th and 7th of the flat key. And in the sharp key, there may be an imitation in the compass of six notes ascending; namely, from the key and its 5th. We have been particular in remarking the want of exactness in imitation on notes belonging to the key. Not that we mean to mark it as a defect; for it is beyond doubt, that every passage in the harmony of the key must be pleasing, whether it be a perfect imitation or not.

Besides, this dissimilitude, arising from the place of

the semitone being changed, is so far from being chargeable with a defect, that, as hath been often said, it produces that sweet variety which is founded in the principles, and which every artill pursuing will succeed in; as in this he doth no other than copy after nature.

These remarks on the imitation of a passage in the notes of the harmony of the key, will lead us to the second manner of imitation; which is such, as that every note in the repetition stands exactly in the same interval respectively as the notes of the first passage.

This then is a perfect imitation. Which, as it cannot take place in the harmony of the key, except in the few cases abovementioned, it must be effected by art; that is, by altering the places of the semitones in the key, so as to correspond with those in the original passage, by marking a sharp for the semitone ascending, if the repetition be in notes above the passage; and a flat for the semitone removed lower, if the repetition be in the descending notes.

In this manner there can be a perfect imitation of any passage of any length whatsoever, and of any compass: in every instance of which, the key is changed, by introducing notes not belonging to the harmony of the same.

As every interval of the first passage must be preserved in the repetition: it will sometimes happen, that many flats, or sharps, must be added to the notes in the repetition. The rule of this practice will be well understood, when we shall have learned the art of transposition; the repetition of any passage in this manner being no other than a transposition of the same into another key. In regard to this perfect imitation, we have one remark: which is, that if a repetition be made on the note next above, and repeated again the note still higher, it will have a good effect; for this will create such a novelty in the strain as is surprising; besides that it affords the author an opportunity both of making new descant or enlarging on the subject in this new key, as well as of shewing the greatest skill by returning from that digression into the original key with art and propriety.

This will be no difficult matter to one who understands well the art of transposition. Now, the repetition of the subject transposed into a key different from the original belongs to this second rule of melody; as the repeating the subject in its own key respects the rule of unity.

The repetition of the subject after these two manners, and throughout the several parts, as treble, bass, tenor, and so on successively and constantly, each part taking it up immediately, or as soon as the repetition is finished in another, whereby the several parts seem to move in pursuit of each other, is called a fugue.

Musick composed on this design is justly esteemed above all other, not only on account of its excellent contrivance, but for the sake of the pleasure also which it affords.

In a just fugue is represented all the variety possible; at the same time that an uniform progression of the parts is preserved throughout the whole, without the least discovery of the signs of art.

The reason for this may be, that the repetition of so interesting a passage as the subject is, is so natural to the imagination

imagination and ear, as not to be easily distinguished as the effect of art. The construction of a fugue will be understood, from this description, to be in the following manner.

The subject being first written in that part which the composer intends to be the leading part, the same must be set down again in the next part wherein the repetition is appointed to be made, either in unison, or on the 4th or 5th to the key or subject, the 2d, or any other interval; in which matter the composer is at liberty.

Yet the repetition on the 4th seems more natural to the flat key; as, on the 5th, it is to the sharp key.

If the musick be in two parts only, the subject being written in each part in succession; the next step will be to frame descant to that part where the repetition is, and which therefore will be written in the leading part. Henceforward the parts move on at liberty, that is, no where repeating the subject, but expressing all the variety in descant each to the other, which the fancy, invention, and skill of the author suggest, until the subject is again repeated, either in the key, or some interval of the harmony of the key, or perhaps in a new key.

The imitation of this must immediately follow in the other part, in unison, or otherwise.

If the musick be of three or four parts, let the subject be first written in every part, in succession; and in the order you intend. Then fill up with descant the second bar, or more, of the leading part; that is, as far as the subject reaches in the other part; and proceed likewise on the next repeating part with other new descant; and so on through every part, until all the staves are equally full.

After which the parts move at liberty, as before in a two-part fugue, until another repetition of the subject.

But where, or how frequent, the repetition of the subject may be made; or on what interval, whether above or below; or by what succession of the parts, (for they need not preserve the order they began in;) is neither the business, nor in the compass of the rules of art to prescribe.

In these matters, the composer is as much at liberty as his genius and invention can furnish matter and variety. So that in some places the subject may be repeated continually, in the different parts, on intervals and in a key different from the original key or order.

Sometimes, the movement of the subject being the same, the notes are changed from ascending to descending, or the contrary. Sometimes even the movement to the contrary. At other times, a new subject is introduced; and then it is called a double fugue. And lastly, for the sake of variety, the subject is repeated backwards, or inverted; so that the parts seem to pass each other by contrary motion, instead of pursuing.

In a word, there is no passage which expresses variety, which may not be introduced in a just fugue; while the uniformity is preserved in the imitation of the same, and resuming the original subject, and key, towards the conclusion or close of the piece.

We shall only add, that if the descant which fills up the bars be constantly written in all the parts successively and in order throughout the whole piece, the fugue

is, from the exactness of this repetition, called a canon. In framing of which, observe, that if the canon consist of three or more parts; when the third part takes up the subject, the descant in the leading part must be part of the harmony of the other two.

What remains to be spoken to on this second rule of melody, or imitation, is the method of returning into the original key, after a passage in a remote one. This will lead us to consider the half-tones not belonging to the harmony of the key, or chromatic notes.

For if a passage, or repetition of a passage, be in a new key, which is the imitation we are now speaking of, the resuming the key immediately will be by chromatic notes; descending if the repetition were above; and if the repetition was in notes below the passage, we may ascend into the key by chromatics likewise, or half-tones ascending.

This is evident. For every key, flat or sharp, having its semitones in their proper places, a passage is not in the key, when the semitones are out of their places.

Therefore the returning into the key, from a passage not in the harmony of the same, must be by removing the new half-tones.

This depends on the knowledge of transposition.

The new semitones introduced in a passage, or imitation of one, we have called chromatic notes; because every semitone not belonging to the harmony of the key are to be found only in the chromatic scale.

Yet this is but improperly. For two, three, or more semitones succeeding each other are properly called chromatic notes; which, to musick wherein the frequent use of these is made, gives the name of chromatic musick.

The use of chromatic notes is to raise the attention by the uncommon and unexpected variety they produce.

For every new half-tone ascending, being understood by the ear as the greater 7th, implies a new key. Three or more semitones ascending after each other, do therefore raise the expectation of so many new keys: whereby the curiosity is greatly excited; and the expectation of the ear being gratified, in the imitation of a close, by every new semitone, the musick becomes, as in all other cases where novelty takes place, truly the object of admiration. In a series of semitones ascending, the last is in the place of the key. When chromatic notes descend, the last but one is the key, for the same reason; namely, the semitone below sounding as the greater 7th, every key being a semitone to its greater 7th or half-tone below relatively.

Chromatic notes ascending, by alarming the ear and imagination, elevate the soul, thereby imitating the sublime.

Chromatic notes descending, express the pathetic, which is free from any alarm or terror. The performance of these notes should always be with softness, which naturally removes the apprehension of terror. Ascending and descending semitones partake of the nature of the sharp and flat keys; as hath been said concerning the power of musical sounds to touch the passions.

Chromatic notes may be introduced in many places.

If, in a passage, the semitones of the key occur among others, they are to be accounted as chromatic. There-
fore

fore flat and sharp keys are equally capable of improvement by them.

Notwithstanding chromatic notes create so much variety and elegance, it must not be understood that they are to be introduced injudiciously, or without any address; for then they would not only be useless, but injure the musick. Chromatic notes being so affecting and expressive, as we have shewn, their place in vocal musick will easily be determined by the sentiment.

As, on the other hand, to introduce lively or pathetic sounds, where the sense is dissonant from either, is introducing contradiction and confusion.

Neither is it natural in instrumental musick to break in upon a lively strain by slowly-moving chromatic notes. Though at the end of a brisk movement, the transition is good. For music which moves in semitones, though quick notes, must appear slow to the ear, which expects the greater intervals of the diatonic scale, or whole tones.

Yet instrumental musick does properly admit the mixture of chromatic notes, when they are accommodated to the genius of the strain or subject. Neither will it be difficult to judge of this propriety. For musical sounds having a natural tendency to express our ideas, the place of chromatics will readily be found by this mark; it being in the power of the composer to imagine ideas without the help or intervention of words, and so substitute these ideas in the place of words, and make them the subject of his strain. Thus he may fill his mind with the imaginary passions of love, sorrow, anger, dejection, pity, and the like; the expressions of which will be most easily distinguished by musical sounds, and varied as the subject requires. Thus, if two or more of the passions, especially contrary ones, be represented by turns, it will form in the imagination a kind of conversation between persons, which never fails to strike the attention stronger, and make a deep impression on the hearer.

Besides this, the imagination of the composer will be assisted in the invention of variety; and the different passages of the piece will be furnished with notes proper and natural to each; for the same reason that choice and expressive words flow in upon a good writer who is master of his subject. We shall only add, that if sometimes the different passages be allotted to the bass and treble by turns, it will greatly diversify the subject, mark the sentiment stronger, and thereby cause new pleasure. So much for chromatic notes. Notwithstanding, what hath been said in this place doth not respect chromatics only; but in general the whole process of an elaborate piece, in every form and transition of the melody; wherein only there is opportunity for application of what we have here suggested.

The reason why we have given place to chromatics under this second rule of melody, or imitation, we have already assigned; namely, that the use of half-tones is necessary where there is a repetition of a passage in another key. For, whatever proportion of sounds is found in the natural order, the same may be transferred by art, and improved upon every occasion, as thereby imitating nature. And this, by the way, is likewise the true reason for the resolution of discords by semitones; being taken from the original pattern, or reso-

lution by the two semitones in the natural series of sounds in the octave.

The third rule of melody is order.

ORDER in musick is the conducting the melody or air, according to a certain rule, through several intermediate closes, from the beginning to the final close or end of the tune.

A close is the termination of a passage in a concord; which, like a period in sense, is framed with design, and from the preparation from the notes immediately preceding, which are the whole tone above, the half tone below, and the 5th (generally the bass note) is expected by the ear. This is the description of a full close, which is ever the final close, especially of quick movements. This preparation is the concord of the 5th to the note on which the close is made; the bass making the great cadence, as we have taught in the rules of composition.

This preparation is in full harmony. But it must be remembered, that there is a preparation also from discord; chiefly the discord of the flat 7th, of which we have said enough in the chapter of discord or figurate descent. In slow movements there is a preparation to a full close; which shall be described presently.

Every intermediate close hath its preparation in imitation of the final close, more or less. For there is no necessity for the parts taking invariably the same member of the chord; so that the treble oft times makes the cadence from the 5th, particularly in quick passages; in which likewise, in the middle of a strain, many imperfect closes may occur, the parts taking the notes indiscriminately as they happen, without any preparation designed. It is enough to mention these.

But in order to conduct the air in each strain, if there be more strains than one, with propriety and method, there must be a full close in several places in the harmony of the key. These are called proper closes.

These are also closes made by the introduction of a new semitone, by the addition of a sharp, making the greater 7th not belonging to the harmony of the key. These are rightly called improper closes.

The places and order of both these we shall now assign.

The first proper close falls naturally on the key. This is not meant of the final close; for a close may be made on the key, within a few bars of the beginning; yet this close is seldom made, as not affording variety. Again, the first strain sometimes closes on the key; yet the close of that strain is more properly on the 5th; and the close next after that on the 5th falls naturally on the key.

When a close is made on the 5th, the 4th of the key being removed a semitone higher, becomes the greater 7th by the addition of a sharp. For, in imitation of the final close on the key, there must be a semitone ascending.

Notwithstanding, a close made on the 5th, with a sharp 3d always, from the chord of the 4th in a flat key, without altering the 4th, or bringing in the greater 7th, is accounted an elegance: in which passage the bass takes the flat 6th or 3d to the 4th, and thence descends by the semitone into the 5th.

This is never practised but in very slow movements.

From

From the necessity of a semitone ascending to every full clofe, except this laft inftance, we draw this inference, That a clofe may be made on every semitone in the key. This afcertains the places in both flat and fharp keys: in the clofes of both which the key is a semitone; in a fharp key, the 4th alto; and in the flat key, the 3d and 6th.

These are the places of proper clofes, or fuch as are made in the harmony of the key.

The order of clofes is now to be confidered, which, in a fharp key, may be thus. The key, the 5th; the key, the 4th; the 5th, the key.

Notwithstanding, every compofer, being at liberty to purfue his own defign, will prefer that order which will fuit beft with the manner of the air, or anfwer his intention. Our bufinefs is only to point out the places where clofes may be made, and give a general idea of the order. For we have obferved much difference in practice among the beft authors; and indeed it cannot be otherwife in long and finifhed pieces, confidering that liberty infeparable from every compofer who invents; and therefore every manner which may increafe variety, is to be recommended.

The order of clofes, then, in the flat key may be, The key, the 3d the 5th, the key.

Or, the key, the 5th the 3d the 5th, the key.

Or again, the 5th the key, the 3d the 5th, the 3d the 6th, the 5th the key.

In pieces of a confiderable length, clofes may be repeated in thefe feveral places, and the fucceffion of them altered from that wherein we have fet them down above.

Improper clofes, or fuch as are made on any other note than the key, flat 3d, 4th, in a fharp key, 5th or 6th in a flat key, are made by bringing in a semitone not in the harmony of the key, by the addition of a flat or fharp, the note below the new-made semitone being always the greater 7th, and which therefore determines the note on which the clofe is to be made.

By this art a clofe may be made on any note; as on the 2d, 3d, 6th, or 7th of a fharp key; on the 2d, 4th, and flat 7th of a flat key. A clofe on the 6th of a fharp key is much in ufe, though no semitone: this depends on the 6th having for harmony its own chord, which will be proved in the next chapter.

It remains to be remarked, that as every new key is formed by the addition of a fharp or flat; fo the return into the former key, whether the original, or otherwife, is effected by taking off the flat or fharp from that note, the next time it occurs in the courfe of the ftain.

In mufick of two parts, the greater 7th, or that which makes the new semitone, will not in every paffage be expreffed; the treble fometimes defcending from the 3d above into the clofe. Yet, if the bafs falls the 5th, thefe two members of the chord do properly lead to the clofe.

However, it muft not be underftood that in every clofe the bafs muft move the fame way, by defcending from the 5th, as was faid before; no part having any member of a chord proper to it by any neceffary or natural dependance; for otherwife the fecond treble, or tenor, could never afcend above the firft, nor the bafs above either; than which nothing is more common. Custom indeed has appointed to the bafs this movement at a clofe,

for the moft part, and efpecially at a full or final clofe: and juftly; the defcending from the 5th, being fo interefting a movement, is better expreffed, as well as more fuitable to the grave notes of an inftrument performing the bafs.

There is another paffage in practice, which, though not a clofe, yet comes properly in this place to be fpoken of. It is a fudden or unexpected ftop of all the parts made on a difcord.

As this is generally praftifed in quick movements; fo it is often, though not always, fucceeded by a flow movement: during this ftop, the ear is held in fufpenfe by the difcord, and waits for the refolution into the concord.

The fuddennefs and novelty of this paffage recommend it. It feems contrary to a clofe: for as, being a difcord, it hath no preparation, and, not being refolved as fo on as the ear expects, feems to lofe its connection with the following chord; its meaning therefore is undetermined, and the fenfe confufed: yet it hath a good effect by alarming the imagination, refembling an affected perturbation in the order of the words and fentences of an oration.

CHAP. V. OF TRANSPOSITION.

TRANSPOSITION is the removing a tune from one key into another. The ufe of tranfpofing is to bring a tune within the compafs of fome inftrument, or for the more eafy performance on an inftrument; fome keys being more difficult to perform in than others; efpecially in wind inftruments, as the German flute, &c. For as to inftruments that are ftopped, as the violin and bafs-viol; and inftruments with keys, as the organ and harpichord; all keys are eafy to a good performer, who is faid to be mafter of the fcale of the inftrument.

Secondly, Transposition is abfolutely neceffary in mufick for voices and inftruments, when it happens that the key in which the mufick is written is too high or too low for one or more of the voices. In this cafe, the mufick muft be tranfpofed for the inftruments into the key which is neareft to and will beft fuit the pitch and compafs of the voice. For as to the vocal performer, it matters not in what key the mufick be written for his part, provided he can fing in the cliff, (or indeed, if he can tranfpofe, as fhall be taught in the laft chapter, Of fing- ing by note, whether he can fing in the cliff before him, or not,) if the inftrument be accommodated to his voice.

There are two ways of tranfpofing. The firft is, when the tune is written in another key, at any diftance above or below the original, with the proper flats or sharps prefixed. When this is done, the performance on the inftrument is eafy; the half tones of the key, and every other, keeping their due places expreffed in the writing. This may be called tranfpofition by writing.

The other method of tranfpofing is by the cliff; that is to fay, when the cliff is removed, or fuppofed to be removed, from the place wherein it ftands prefixed to the tune.

This removal of the cliff at once tranfpofes the whole, without alteration of the writing; the ufe of the cliff being, as hath been faid, to afcertain the names of the notes. We fhall fhew both thefe methods of tranfpofition; and firft of tranfpofition by writing.

Transposition

Transposition, in general, is writing or playing a tune in a different key from that wherein it is written, preserving the places of all the semitones.

If the notes in the scale of musick expressed no other than whole tones, transposition would be evident to sight. For a series of tones at equal intervals would, when removed to any distance or interval, preserve their places of themselves (so to speak,) or without the help of art. And the performance of the same on an instrument would be equally easy in all keys; no alteration happening thereby, but changing the names of the notes. And even this would be unnecessary.

The semitones therefore are the causes of any obliquity in the scale of transposition; and therefore the keeping them in their due places is the art we are now speaking of. As it is said in the theory, they are the foundation of writing the same tune in divers keys, which is transposition.

We must have recourse therefore to what hath been said in the theory concerning the essential difference of tune, or the different places of the semitone.

When the first semitone above the key is on the 4th, or 6 semitones to the key; the 3d, which is 5 semitones, is the greater, or sharp 3d; and the tune is from hence said to be in a sharp key.

Again, when the first semitone above the key is on the 3d, or 4 semitones to the key, that being the lesser or flat 3d, the tune is in a flat key. Again, the next semitone in the sharp key is the 8th; and in the flat key on the 6th.

In every sharp key, the semitone must stand in the same places, that is, the 4th and 8th; and in the flat key, in the 3d and 6th.

The name of the sharp key in the scale, whose semitones are in their places without the addition of flat or sharp, is C. Hence C is called the naturally sharp key. Its semitones are F and C.

This is the pattern for transposing in all sharp keys: chiefly by remembering the letters or names of the semitones.

The key in the scale, whose semitones are in their places without the addition of flat or sharp, is A. Hence this is called the naturally flat key. Its semitones are C and F. This is the pattern for transposing in all flat keys; remembering the names of the semitones.

It may be required to transpose from any key with a sharp 3d, into any other of the same; or likewise from any flat key respectively. Notwithstanding, we shall proceed, according to our method, to shew what are the keys in the natural succession into which a tune will be transposed, beginning at C the naturally sharp key. As the properties of every key will be discovered by this method; so it will answer every thing that can be required in transposition; or shew how a tune may immediately be transposed from any key into any other interval or key that may be required.

For instance, let it be required to transpose from the key of C into that which is next in the natural order of transposition. F is the first semitone in the key of C; which, by the addition of a sharp, becomes F sharp; and consequently the greater 7th to the semitone above it,

which is G. Therefore G is the new key into which the tune is transposed. No. 99. For,

Again, let it be required to find the next key to be transposed into, from the former, or G.

The first semitone in the key of G is C: which by the addition of a sharp, which is removing the semitone, becomes C sharp, or the greater 7th: therefore the new key is D. No. 100. For,

Observe that every former sharp which is set down for the tune transposed, is included in every succeeding transposition. That is to say, C, for instance, cannot be marked sharp, unless also F be marked.

The reason of proportion demonstrates this to sight. These are the two semitones of the open keys, as they are termed; the observation will hold true of all others, as will be seen in the following instances.

To transpose out of D into the next key; the first semitone in the key of D is G. But G sharp is the greater 7th to A. Therefore A is the new key. No. 101.

Take notice, that the first semitone, or 4th in the sharp key, being removed by the addition of a sharp; the tune is hereby transposed into the 5th to the key.

This removal into the 5th, by changing the first semitone, being the same in all sharp keys, it need not be repeated in more examples. For the next to A will consequently be E, with the addition of A sharp to D.

The next B with A sharp.

The next will be F sharp with E sharp; never used.

The next would be C sharp with B sharp; never used.

The next would be G sharp with F having two sharps; never used.

The next is D sharp, with C having two sharps; which last is D natural. This key is in frequent use: but the name of the key is changed, and marked with its equivalent E flat: and the name of its greater 7th is likewise changed; and, instead of C having two sharps, is left, as in truth it is, D natural.

The next is B flat; its greater 7th A natural.

The next is F natural; its greater 7th E natural. From this we ascend, according to the rule, by a 5th into C where we began.

Hence it is evident, that of the twelve semitones in the octave, nine are in use as keys with a sharp 3d.

Of which the following are examples in their order. No. 102.

The last three examples marked with flats may be demonstrated in another manner; which is, by changing the place of the other semitone, or 8th, by removing the sharp 7th, by prefixing to it a flat. The transposition will, by this alteration, happen in an inverted order from that in the foregoing examples. For, as the 4th or first semitone in the former manner, being removed by the addition of a sharp, became the greater 7th; so in this case, the greater 7th being removed by prefixing a flat to it, becomes the 4th of the next key. No. 103.

This manner of demonstrating the last three keys is preferable. For, by changing the first semitone, as in the former manner, it doth not so plainly appear, as that depends upon the foregoing key, which never was in use. Besides, the number of sharps to be prefixed to these keys might perplex a beginner in transposing; whereas the

†

4 S

flat,

flats, as prefixed in the example, do more methodically follow the removing the greater 7th by a flat.

The demonstration is equally certain and clear in both manners. Let it be remembered, that in transposing, by altering the greater 7th, the key is removed to the 4th above.

Let us proceed to transposition in a flat key: the general rule of which is the same as for the sharp, to remove the semitones, and thereby preserve the proportion of the key.

The different places of the semitone will cause some variation in the effect, or interval of transposition.

Let it be required, according to our method, to transpose out of the open or naturally flat key A, into that which is next by natural succession.

The first semitone in the key of A is the 3d, or C; which, by the addition of a sharp, becomes the greater 7th: wherefore, the new key, or that into which the tune will be transposed, is D. No. 104. For,

Let it be remarked, that the greater 7th which determines the new key in this as well as in the sharp key, is never prefixed to the tune; which to the sharp key always is.

The reason is, that the flat 7th is the property of the flat key. To prefix therefore a sharp to the place of this note on the staff, or beginning of the tune, would be a constant contradiction to all the flat 7ths that may occur throughout the whole air. But the sharp 7th, when brought in at a close, middle or final, or elsewhere where there is no close, is marked particularly as occasion requires.

Another reason for not prefixing a sharp on the staff to the place of the 7th of a flat key is, that, in some keys, the 6th must have its flat set on the staff, or beginning of the writing: a sharp, then, on the place of the 7th would appear a contradiction to sight, and ought therefore to be avoided.

The removal by transposition in the flat key being always to the 4th above, as in the last example, there needs no other example at length of transposition in this key, the same proportion obtaining throughout every key with a flat 3d respectively.

According, then, to this proportion, the next key after D will be G; the 3d of the former, or F natural, becoming F sharp the greater 7th, E flat its 6th.

The next will be C. Its greater 7th is B natural, with the addition of a flat to A its 6th.

The next will be F, with the addition of a flat to D its 6th.

The next would be B flat, with the addition of a flat to G its 6th, never used.

The next would be E flat, with the addition of C flat its 6th, never used.

The next would be A flat, with the addition of a flat to F its 6th, never used.

The next would be D flat, with the addition of two flats to B, never used.

The next would be F sharp, its 6th D, never used.

The next is B, its greater 7th A sharp.

The next is E, from whence we ascend by a 4th into the first key A.

Hence it is plain there are seven flat keys in use, out of the twelve semitones in the octave. Of which the following are examples, with their proper signs prefixed, No. 104.

It may be observed, that by changing the place of the other semitone or 6th, by adding a sharp, the transposition is by two degrees of the former at once; as from A into G, and so on. But this is no more than what hath been done in the second step of this example; yet by putting this sharp to the 6th, it is a short way of transposing into the whole tone below.

It appears from hence, that there are in all sixteen keys in use; a fund for great variety: among which you will observe, that some sharp keys have flats prefixed, and some flat keys have sharps; which cannot by this time appear strange to one who perceives the necessity of preserving the proportion of each, and who must now understand the truth of the 3d axiom of the practice, That no tune composed in a sharp key can be transposed into a flat one, nor a flat one into a sharp; for that would be altering the permanent nature of things.

From comparison of the examples, will be seen what is most worthy of remarking; which is, That whatever sharps or flats belong to any flat key, the same are likewise the property of that sharp key, which is on the same flat key's 3d: for instance, A with a flat 3d, and C with a sharp 3d; so D and F, G and B; and so of all others respectively having the same signs belonging to and prefixed to each.

Hence we collect, that the essential difference of tune consists in the form, that is, the position of the semitone, and not in the materials of music.

A truth which appeared before in the comparison of discord with harmony; and which will be of great service hereafter, in the art of learning to sing by note.

This inference furnishes us with a proof of the 4th of a flat key, and 6th of a sharp key, having for harmony each his own concord.

A proof which was wanting; as it could not be had from the rules of harmony, neither of these intervals being in the place of a semitone. The general theorem is this: As by axiom 2d the proportion of one single sound is to another according to the natural order of sounds; so the proportion of one chord to another will be according to the natural succession of chords. For a chord is no other than an unity of sounds. But it appears that the succession of chords by transposition in the flat key, is by 4ths, that is, the chord of a note, with a flat 3d; and that of the note's 4th is the same. Now, the harmony of the key or given note is the concord of itself: therefore the harmony of the 4th in a flat key is the concord of itself.

In like manner we demonstrate the harmony of the 6th of a sharp key to be the chord of the same.

And in this the proof lies nearer the truth than in the former case.

For the chord or proportion here is not only the same, but the individual sounds.

For as by comparison, as above, of any flat key with the key of its 3d (which must ever be a sharp key, the flat and sharp 3ds being the compound intervals of the 5th) the

the properties and proportions are not only like, but the same, the difference consisting in the form or place of the semitone; so the chord of one key will be to the chord of the other, not only like, but the same. Now the harmony of every flat key is, by the rules of harmony, the concord of itself: but the concord of the flat key is the relative sharp key's 6th; therefore the harmony or chord of the sharp key's 6th is the concord of itself.

Let us now apply these rules of transposition to the second rule of melody, or perfect imitation, which is the repetition of a passage in notes not belonging to the harmony of the key; by which notes we understand all that have a sharp or flat added, which was not prefixed to the beginning of the staff or tune.

The general rule of which is, First name the key in which the passage is written, whether the same be the original key, or that of the tune, or some other; then name the interval of the first note of the passage to the same key.

Whatever interval the imitation begins on, whether a 2d, 3d, 4th, 5th, or any other above or below the passage, it bears the same proportion to the key of the imitation as the first note of the passage to its key. Thus

G is to C as A is to D, or
G : C :: B : E, or again
D : A :: B : F, or
D : B :: E : C.

The leading note and key being thus expressed, both of the passage and imitation, shews the proportion of the imitation above or below passage.

If the passage be in a sharp 3d, as the imitation must be so too, the signs, as prefixed to one of the examples of the sharp keys, will be required to be added to the notes of the imitation; and if the passage move with a flat 3d, the examples of the flat key discover the marks wanting in the repetition.

Thus G, the leading note of a passage in C, with a sharp 3d, repeated in the note above; as A and D require two sharps, namely on F and C, the property of D with a sharp 3d.

And the same passage in C with a flat 3d, will in the note above require B marked flat, the property of D with a flat 3d:

And G C sharp 3d, transposed into a 3d, or B E, requires four sharps, on F, C, G, and D, the properties of E with a sharp 3d.

The same passage with a flat 3d, or any other passage, will, when transposed into E, require but one sharp on F:

And D B, with a sharp 3d repeated in E C the natural sharp key, require neither sharp nor flat.

But the same, or any other passage with a flat 3d, will, when transposed into C, have three flats on B, E, and A, the property of C with a flat 3d: and if there be no leading note, as it may often happen, nothing more is to be considered than the key.

Thus the use of transposition in perfect imitation is evident.

The second method of transposition is by the cliff.

The use of the cliff is to ascertain the names of the

notes. Therefore, the names of the notes will be changed by removal of the cliff.

Now as, in transposing, it is necessary that every interval be preserved, or that the semitones keep their due places; so by altering the name of the first note of the tune, by removing the cliff, all the other notes are altered in proportion.

Thus the removal of the cliff effects at once what was done in the other method by the transposition of every single note of the tune by writing.

This way is easier to the writer, but much more difficult to the performer.

Inasmuch as a confirmed habit in any thing is harder to be changed for a new method, than it is to learn by a certain rule at first.

Therefore the performance in transposition by the cliff can no otherwise be attained, than by constant and repeated practice in all the cliffs, and in all such places as they are used to be set for convenience.

Every one therefore who desires to become a master in performance, after he is well acquainted with the three cliffs in their usual places, ought to accustom himself to perform in every cliff, in whatever place it may be set. This knowledge will not only render the performance convenient to his private amusement, by the variety with which he can furnish himself, by playing the same air in whatever key he pleases; but will also make him an useful member in a concert, by transposing at sight, whenever it may be required to accommodate the instrument to the voice. For let it be understood, that to him who is so well acquainted with the places of the cliffs, as to perform in any of them at sight, nothing more is wanting to his transposing by the cliff at sight than to imagine the cliff is prefixed to such or such a place, and commit to his memory the name of the key in which he is to perform, by transposing according to the removal of the cliff which may be most convenient.

This will fix the places of the semitones, or assign the sharps or flats belonging to the new key, as they are set in the example in the first method of transposing by the writing.

Any of the cliffs may be removed; yet the C cliff or tenor is most commonly in use for this purpose.

The general rule for transposition by the cliff is this.

To transpose into any interval above the key, remove the cliff by the same interval descending. And if the instrument be too high for the voice, to transpose into a lower key, remove the cliff to a convenient interval higher.

For, raising the cliff depresses the notes; and, contrary, setting the cliff lower raises the notes, or transposes them into a higher key, in proportion.

CHAP. VI. OF SINGING BY NOTE.

THE art of signing by note is founded on the principles and practice of music. Therefore we have reserved this subject to the last.

To sing by note seems in some respects more difficult to attain than performance on some instruments. In other respects, it is easier and sooner acquired.

The more time is laid out on the practice on some instruments, the more difficult the execution grows, in some sense, that is, according to the construction and compass of the instrument. On the contrary, all the difficulties in learning to sing by note present themselves in the beginning, in appearance greater than they really are; and which a knowledge of the principles of musick, and a little of the practice, with a tolerable good ear, will with ease overcome.

Besides, a little time and experience will convince any one of what compass his voice is, and what degree of performance he is capable of attaining. The principles of singing therefore being well understood, there remains no further difficulty; no one having a right to expect he can execute more than what is within his natural powers.

If this art is not so commonly understood, or the knowledge of it sought, it may be owing to this, that the precepts for learning, or the manner invented, and constantly used, are more perplexed than the subject demands.

How far this may be true, will appear from an observation or two which we shall make on the method now in use.

The art of singing by note rests on these two principles; the finding the places of the semitones, and tuning them and the whole tones of the octave aright.

The first of these has been delivered in the theory; and also in the practice, under the last article Transposition. The tuning the notes is the subject we are now engaged in.

Let us first examine how far these have been profecuted in the present method.

The notes of the octave, besides their names in the scale, have been used to be distinguished by these four syllable, Sol, la, mi, fa; accommodated to the purpose of singing by note, in the following order.

Fa. sol, la, mi, fa, sol, la.

Whereof Sol being thrice repeated in the octave, La twice, Fa twice, and Mi once; four syllables express the 8 notes.

The art of tuning by these, or assigning the places of the semitones, is by appointing to Mi the place of the greater 7th; and then Fa immediately following expresses the semitone or key, and the other Fa, the 4th. How well forever this may answer the purpose of tuning the half-tones in a sharp key; yet in a flat key, the places of the half tones being the 3d and 6th, will, according to this order, be expressed by La, the semitone syllable Fa consequently expressing whole tones.

To obviate this difficulty, and reduce things to order, another place of Mi must be assigned, which is the 2d of a flat key: for this Fa will express the semitones on the 3d and 6th.

It is evident then, that before any half-tone or whole-tone can be tuned, the first business must be to find out the place of this mi: now how this can be done by virtue of the sound, or name, or order of these syllables, is not so easy to comprehend.

But admitting the place of mi, or the key, to be known by some previous precept, as indeed ought to be; yet

tuning the key as the first semitone in a sharp 3d, and the 3d as the first semitone in a flat key, is beginning at the wrong end in the first case, and thereby not marking the essential difference of tune, which consists in the flat and sharp 3ds, the order of which is disturbed by this variation of the place of mi.

From this want of marking the essential difference in tuning by these syllables, and wherein the beginning and ending is not on the key, some confusion and much trouble and untunableness must arise. And indeed it cannot be imagined, that this or any other essential difference of things can be marked by the same invariable artificial signs, if they be not exactly accommodated to the nature of things. An invention that fails in this, however ingenious it may be in speculation, not being a just representation of nature, doth not merit the name of art.

For instance, if you tune eight notes, whose key hath a sharp 3d beginning on the 5th, your seventh note, which is the 4th of the key, and therefore a whole tone from the succeeding note, will sound like the flat 7th. Again, if you begin to tune on the 2d, your 3d, which is the 4th of the key, is flat; and the sound in this succession will appear as if you were tuning in a flat key.

And again, if you tune from the 6th, the deception of a flat 3d is the same as in the last case.

Secondly, if you tune 8 notes whose key hath a flat 3d, and begin on the 7th, your 3d, which is the 2d of the key, is sharp, and your tuning will be as if in a sharp key.

The same deception will appear if you begin to tune on the 3d or 6th.

In a word, whatever other interval you begin on, to tune either with flat or sharp 3d except the key, some semitones will be out of their places: This is rendering what is at first sight attended with some difficulty, more perplexed and obscure.

The ear, the judge of sounds, is deceived, and the judgment misled.

But on the other hand, the ear will naturally and easily distinguish the flat and sharp key, when the key and its 3d are ascertained by beginning and ending on the key.

But otherwise, and where these marks are promiscuously used, the difference of tune, or infallible sign, will appear neither to the ear nor understanding.

We shall end these remarks with one general observation; which is, that by assigning the place of mi to the greater 7th or 2d, in order to find out the key, is resolving one difficulty by a greater and requiring to do a thing without any means of information offered to compass it.

For as it is true that when the greater 7th or 2d is known, the key is known also, and again, the key being given, you have consequently the 7th or 2d; yet to do either of these, without some intermediate helps, is taking for known the thing sought, which is directly contrary to reason.

Proceed we now to our method of singing by note.

The first principle of singing, is the finding the places of the two semitones in the octave, in any given key

This

This hath been pointed out in general, in the theory, where are shewn the places of the semitones in the sharp key to be the 4th and 8th, and in the flat key the 3d and 6th.

But the particular names of the notes, on which the semitones fall in any key whatsoever, and which it is evident must depend on the name of the key, are demonstrated, and examples given, in the practice, under the article of Transposition.

We shall therefore transfer only the examples into this place, in a concise order, which will fully answer our inquiry into the names and places of the semitones.

The nine sharp keys. No. 106.

The seven flat keys. No. 107.

By these examples the particular names of all the semitones are known at sight; as they depend on the name of the key.

Therefore in the example of the sharp keys; the first key being C, the semitones are F and C.

The second G; the semitones C and G.

The third D; the semitones G and D, the 4th and 8th of each respectively.

In the example of the flat keys; the first being A, the semitones are C and F.

The second D; the semitones are F and B flat.

The third G; the semitones B flat and E flat. And so on, the 3ds and 6ths respectively.

To apply this to the purpose of tuning the notes by the voice: At sight of the sharps or flats prefixed to the tune to be sung, and looking at the key-note, you have of course the places of the semitones, by referring these to the original in the examples set above.

Having thus discovered the difference of tune, you are at the same time determined whether you are to tune the notes of the octave with a flat or sharp 3d.

This tuning of the eight notes, tones and semitones, in their due order, is the first step or principle of tuning all other intervals, or of singing by note.

It will most readily be learned by imitating another voice, or following the notes of an instrument; this is the only case wherein there is need of any foreign assistance to singing by note.

The instrument we would recommend for this purpose is the organ or harpsichord; as the 4 or 5 semitones, which ascertain the flat or sharp 3d, succeeding each other, being visible on the keys of that instrument in any part, the learner can in this case assist himself, by striking the notes of the octave in either flat or sharp key, on any part of the instrument which will best suit the pitch of his voice, and distinctly repeating them by turns, until his ear is become a perfect judge of the difference of the flat and sharp 3d, as well descending as ascending, and his voice perfect in tuning both.

As musical sounds will be best expressed in tuning by articulate ones; we shall, to answer this convenience, take the four syllables already in use.

As we shall apply them to another purpose than they serve at present; so the order or manner we shall dispose them in, will be altogether different from that.

In tuning, then, the notes of the octave with the instru-

ment, let the syllables be expressed with the notes, in the order of the following examples.

In G sharp. No. 108.

Now, since the flats or sharps adjusting the semitones of any sharp key are exactly the same which belong to the flat key respectively on the 6th, as we have said before in comparing the examples of flat and sharp keys in transposition; therefore the eight notes ascending in a flat key will have the syllables annexed to each, as in the following example on the 6th, without disturbing or departing from the order of the sharp.

In E flat. No. 109.

The semitones and the tones below them being distinguished by the syllables fa and mi, in their respective places in both keys, for descending as well as ascending notes, is the sole use we intend by these syllables; the tuning of the notes, which is to be learned by the instrument, being entirely independent of them.

For tuning the descending notes then, there need no other examples than the two above written; for reading the same backwards will serve this purpose.

When the ear becomes well acquainted with tuning the notes of the octave by the instrument, it will then be proper to sing the same looking on the notes written on the book; and this should be done in every example of both keys. And let it be remembered, that tuning the notes thus in the natural order, should be to a beginner the prelude to singing any song proposed.

The next step will be, before the learner attempts to sing any part of a song, to tune by the notes the greater intervals, both concord and discord.

The general rule for which is, Tune all the notes of the interval in the natural order, ascending if the interval ascend, and descending if the interval descend. Then immediately tune both notes of the interval, beginning with the concords.

Thus. No. 110.

Concords in succession.

The discords are. No. 111.

The semitone being the distance between the 3d and 4th, is already known by tuning the notes of this interval.

Note, The name of every greater 7th introduced by a sharp prefixed, is mi.

Next tune the concords of the thirds in succession. In this manner. No. 112.

The 4ths and 5ths being all perfect and like, except one of each, need no repetition.

The 6ths in succession are tuned thus. No. 113.

Lastly, mix the discords and concords as they stand in the natural order; than which nothing will better confirm the just tuning of the intervals, when these rules are to be applied to future practice.

In this manner. No. 114.

This line may be tuned various ways; as, secondly, beginning still on the left hand, tune the 3d and 2d notes, reading backwards; and so on, each two under the slur.

Again, beginning on the right hand, tune the uppermost note and second downwards; then the first and third; and

4 T

†

so

so on, still missing one, and omitting constantly the G, or key not below.

And lastly, beginning still on the right hand, tune the second and first, the third and first, the fourth and first, and so on, omitting the G or key-note constantly.

The practice of tuning the notes descending of all these examples, is by reading the same backwards.

The tuning the greater intervals in the flat key depending in like manner on tuning the eight notes in succession, according to that series; it is unnecessary to set examples of the same.

The same method of practice equally serving this key, except that the syllables annexed to this key must be repeated, as in the proper example 109.

As in this example of the intervals of the 3d, 6th, and 7th, wherein this key differs from the sharp. No. 115.

The general rule of tuning the intermediate notes of each interval first likewise taking place here.

In order to establish these rules in the memory, and render them of immediate service to the practitioner, especial notice must be taken of the flat and sharp thirds, as also of the flat and sharp sixths, in what places they stand, or how they succeed each other in the order of the key.

The not attending to these differences being the only obstacle that can stand in the way of singing at sight, see them set down at large in the theory, and in the examples of this chapter, No. 112, 113.

When these are well recorded in the memory, together with the sharp 4th or flat 5th, the art of singing by note will not appear so mysterious. This knowledge of the intervals at sight will render the syllables of little or no use, as hath been observed, and especially if words be set to the airs you intend to practice; which we would advise.

When the interval of each note is known at sight by constant practice, and the sound of every interval become familiar to the ear, and thereby distinguished immediately upon hearing the same, the learner may make an essay to sing by note some plain song; which is no more than tuning the same intervals, with which he is supposed to be well acquainted in the foregoing lessons.

For as to any other article of knowledge requisite to the performance of the song; as the time of the movement, and lengths of the notes, and the like; if the practitioner hath not been acquainted with them by practice on some instrument beforehand, the principles of them have been delivered in few words in the introduction to this essay.

But besides that this is not the place for speaking of these matters, so neither is there occasion for this knowledge in the very beginning, in strictness of speaking; it being advisable for a beginner to study the tuning the intervals of the song, without respect to any other affection of the sounds; and when he is master of this, to add the practice of the lengths of the notes, as a second consideration.

We shall here set the notes of a plain song, in order to make such application of the rules as may be an in-

troduction towards the further execution of them. No. 116.

First, find out the key, by looking at the last or key notes; then see whether it hath a flat or sharp 3d.

The key of this example being G, with one sharp prefixed, is a sharp key; being the second instance in the examples of the nine sharp keys.

Therefore tune the notes of the octave ascending, and descending, in a sharp 3d. Immediately after tune the concords in succession. After that, tune the concords of the 3ds, ascending and descending. This will be prelude enough for fixing your attention and ear to the 3ds of the key, and for pitching your voice. Having repeated this two or three times, begin the song in the same pitch or key wherein you sung the prelude. For nothing contributes more to singing in tune, than frequent repetition of notes in one key. Therefore, if your voice be rightly pitched in the prelude, seek not to change it in the song.

The two first notes in the example are Fa, Mi: which interval, it is presumed, you can tune at sight. If otherwise, you must have recourse to the general rule, and tune the intermediate note of that interval ascending, thus, Fa, sol, mi; immediately repeating the interval you want to found, thus, Fa, Mi.

The next note is the 2d, or Sol, which may be tuned from Mi, the last note, by descending; or from the key, as it hath an equal reference to both. We have laid before you this choice in consideration of your first attempt. But when from experience you are become more perfect in tuning the intervals, the most approved way will be, to make the last note you sung relative to the succeeding one, whose interval you are to tune. Whereby your singing an air will be no other than tuning the intervals as they succeed each other in the movement of the song; which you practise often before in the natural order, and with which you are supposed to be well acquainted.

The fourth note in the example being Sol, and a 4th to the last note you sung, you will now tune a perfect 4th; not considering this note in relation to the key, to which it is a 5th; but in relation to the last sounded note Sol, to which it is a 4th.

This is the method you will pursue in every interval after some improvement gained by practice. Notwithstanding, it will be convenient sometimes to have recourse to the key, by sounding it, and taking the interval from the same; whereby you will sing better in tune by keeping to the pitch or key you began in; particularly if the interval from the last note be a great one, or discord, or lie near the key, above or below.

To sum up all; every new note introduced, or not belonging to the harmony of the key, bearing the proportion of some concord or discord, to the preceding note or to the key, will come within the rules laid down, and therefore needs no repetition.

On the principles of the theory and practice of musick, we shall now demonstrate the art of transposing with the voice, or singing in any cliff at sight, wherewith it may happen a person is not acquainted; and this from the knowledge of singing in any other cliff.

Plate. C XXXI. *Andante*

The first system of musical notation consists of five staves. The first staff is in treble clef with a 2/2 time signature. The second staff is in treble clef. The third staff is in treble clef. The fourth staff is in bass clef. The fifth staff is in bass clef. The music is written in a style that suggests a slow, steady pace, with many whole and half notes. A double bar line is present after the 56th measure.

56

The second system of musical notation consists of five staves. The first staff is in treble clef. The second staff is in treble clef. The third staff is in treble clef. The fourth staff is in bass clef. The fifth staff is in bass clef. The music continues from the first system, with a double bar line after the 96th measure.

The third system of musical notation consists of five staves. The first staff is in treble clef. The second staff is in treble clef. The third staff is in treble clef. The fourth staff is in bass clef. The fifth staff is in bass clef. The music continues from the second system, with a double bar line after the 100th measure.

) Andante

This section of the musical score consists of six staves. The first five staves are in G major (one sharp) and 3/2 time. Each staff begins with a treble clef and a key signature of one sharp (F#). The first measure of each staff contains a whole note, followed by a double bar line. After the double bar line, the music continues with eighth and sixteenth notes. The sixth staff is in bass clef and also in G major (one sharp) and 3/2 time. The tempo marking 'Grave' is written above the first staff.

This section of the musical score consists of seven staves. The first staff is marked '62 Andante' and is in C major (no sharps or flats) and common time (C). The subsequent staves are also in C major and common time. The first staff begins with a treble clef and a key signature of no sharps or flats. The music continues with eighth and sixteenth notes, some of which are beamed together. The tempo marking 'Andante' is written above the first staff.

Grave

Plate CXXIX

Andante

This is a handwritten musical score on aged paper, featuring 14 staves. The notation is in a historical style, likely from the 18th or 19th century. The first six staves are marked with a '2/2' time signature and a 'C' time signature, indicating a slow tempo. The seventh staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The eighth staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The ninth staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The tenth staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The eleventh staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The twelfth staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The thirteenth staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The fourteenth staff is marked with a '3/4' time signature and a 'C' time signature, indicating a moderate tempo. The score includes various musical notations such as notes, rests, and bar lines. There are also some markings above the staves, possibly indicating fingerings or other performance instructions. The paper shows signs of age, including discoloration and some wear.

This is a handwritten musical score, identified as Plate CXXX. The score is written on multiple staves, alternating between treble and bass clefs. The notation includes various musical symbols such as notes, rests, and ornaments. The score is divided into sections, with measures 68 and 69 clearly marked. The key signature is D major, indicated by two sharps (F# and C#). The time signature is 3/4. The score includes a section marked 'Andante' in the lower part. The handwriting is in ink on aged paper, and the notation is characteristic of 18th or 19th-century musical manuscripts.

68

69

70

Andante

Handwritten musical score, Plate CXXXII, featuring multiple staves with musical notation, including notes, rests, and accidentals. The score is divided into measures, with measure numbers 90 through 104 visible. The notation includes various clefs (treble and bass), key signatures (sharps and flats), and time signatures. The score is written on aged, yellowed paper.

Measures 90-93: Treble and Bass staves with notes and accidentals. Measure 92 has a "2" above it. Measure 93 has a "3" above it.

Measures 94-97: Treble and Bass staves. Measure 95 has a "5" above it. Measure 96 has a "6" above it. Measure 97 has a "7" above it.

Measures 98-100: Treble and Bass staves. Measure 98 has a "8" above it. Measure 99 has a "9" above it. Measure 100 has a "10" above it. Measure 101 has a "11" above it.

Measures 102-104: Treble and Bass staves. Measure 102 has a "12" above it. Measure 103 has a "13" above it. Measure 104 has a "14" above it. Measure 104 has "3d" and "6th" written below it.

Annotations: "2d 3d 2d 5th 6th Note" is written above measure 99. "Semi:" is written below measure 99. "are proportional" is written below measure 100.

120

THEOREM. The intervals of the notes of all sharp keys and flat keys respectively, are proportional. Therefore, the fingering at sight in an unknown cliff will be by transposing out of the given cliff, into that you are acquainted with.

This is done by naming the key in the cliff you are to transpose into, and distinguishing whether the song hath a flat or sharp 3d, compared to the examples of the nine sharp and seven flat keys in use, knowing the name of each cliff. Now, the name of the bass cliff is F, of the tenor C, and of the treble G.

Let it be required to sing the notes in the following example in the bass cliff unknown; transposed into the treble with which you are acquainted. No. 117.

The notes in the uppermost line, in the bass cliff, are in G.

In the second line and treble cliff, they are in E.

DEMONSTRATION. By the rules of transposition they are the second and fifth instances in the sharp key; then they are proportional: if proportional, the semitones are preserved in their proper places: but keeping or singing the semitones in their places, is tuning the notes of the octave right; therefore this transposition from the bass cliff into the treble is singing by note right.

The same example in the tenor. No. 118.

The notes of the tenor are in F; those of the treble in E. But they are the ninth and fifth instances of sharp keys, therefore proportional; and if proportional, &c.

Again, let the treble be the unknown cliff. No. 119.

M U S

MUSK, a dry, light, and friable substance, of a dark blackish colour, tinged with purple; it is a kind of perfume of a very strong scent, and only agreeable when in a very small quantity, or moderated by the mixture of some other perfume. It is found in a kind of bag or tumour which grows under the belly of the muschus moschiferus. See **MOSCHUS**.

Musk is brought tous sewed up in a kind of bladders or cases of skin of the bigness of a pigeon's egg, or larger, each containing from two or three drams to an ounce of musk. These are covered with a brownish hair, and are the real capsules in which the musk is lodged while on the animal. That which is unadulterated appears in masses, of loose and friable granules, which are soft to the touch, and easily crumble between the fingers, feeling somewhat smooth and unctuous.

Musk taken inwardly produces ease from pain, quiet sleep, and a copious diaphoresis: hence it has been found of great use in spasmodic disorders, petechial, malignant, putrid fevers, the jail distemper, hiccoughs, &c. and Dr Wall observes, that it has been found useful in spasmodic disorders, given by way of clyster. The operation of musk in some respects resembles that of opium; but it does not leave behind it any stupor or languidness, which the latter often does. Musk likewise seems likely to answer in those low cases where

The notes of the treble are in D, of the tenor in C. they are the third and fifth instances of sharp keys; therefore proportional, &c.

This demonstration from proportion extends to all possible cases, and therefore makes the proposition universal.

The last example shall be in the tenor cliff, set in the usual places, and in a flat key. No. 120.

In the upper staff the key is G.

In the second, B.

In the third, D. But these keys are the third, the sixth and second instances of the seven flat keys; hence they are proportional: therefore singing them in this proportion is preserving the semitones; and therefore singing them right.

On these principles, it is apprehended, the art of singing by note is rendered intelligible. and the performance tolerably easy; and this especially by removing the difficulties which have taken their rise from the manner of delivering the precepts, and from the usage of variety of cliffs: difficulties, which are the effects, we may say, of too much art, and for this reason perhaps the more perplexing; for whatever of this kind may arise from the nature of the subject of any science, the same may by attention and study in time be surmounted, such cases lying open to every one's inquiry; it being the business of every searcher into nature to contemplate the things themselves, and to make the best use of such discoveries as offer themselves towards the further improvement of science.

M U S

sleep is much wanted, and opiates are improper. It is said to be best given in a bolus, in which form those who are most averse to perfumes may take it without inconvenience. Fifteen grains or more are now given in a dose with great success.

MUSKET, a fire-arm born on the shoulder, and used in war. The length of a musket is fixed at three feet eight inches from the muzzle to the pan, and it carries a ball of sixteen to the pound.

MUSKETOON, a kind of short thick musket, whose bore is the thirty-eighth part of its length: it carries five ounces of iron, or seven and a half of lead, with an equal quantity of powder. This is the shortest sort of blunderbusses.

MUSLIN, a fine sort of cotton cloth, which bears a downy knap on its surface. There are several sorts of muslins brought from the East-Indies, and more particularly from Bengal; such as doreas, betelles, mulmuls, tanjees, &c.

MUSSÆNDA, in botany, a genus of the pentandria monogynia class. The corolla is funnel-shaped; it has two thickish stigmata; the berry is oblong, and the seeds are disposed into four series. There is but one species, a native of India.

MUSSELBOROUGH, a port-town of Scotland, in the shire of Lothian, six miles east of Edinburgh.

MUSTARD, in botany. See **SINAPI**.

MUS-

MUSTELLA, in zoology, a genus of quadrupeds of the order of *feræ*. There are six erect, sharp, distinct teeth in the upper jaw, and an equal number in the under jaw, but blunter and closer together, and two of them are situated a little farther within the mouth; and the tongue is smooth. There are 11 species, *viz.* 1. The *lutris*, with the hind-feet palmated, and the tail about one fourth of the length of the body. It is found in Asia and North America. 2. The *lutra*, or otter, has palmated feet, and a tail about one half of the length of the body. This animal is exceedingly voracious; but is fonder of fish than of flesh. He seldom quits the banks of rivers, and can remain a considerable time below water. The female comes in season in the winter, and brings forth three or four young in March. This animal is found in most countries of Europe and North America. 3. The *lutreola* has hairy palmated feet, and a white mouth. It is a native of Finland, and feeds upon frogs and fishes. 4. The *barbata*, is of a reddish colour; and the toes are not connected with a membrane. It is a native of Brazil. 5. The *gulo* is of a dusky red colour, and blackish on the middle of the back. It is found on the woody mountains of Lapland, Russia, and Siberia. The *gulo* is a very voracious animal, and devours hairs, birds, &c. He has an abominable odor; but his fur is very precious. 6. The *martes*, or marten, is of a blackish yellow colour, with a pale throat, and the toes are not webbed. This animal is a native of the southern parts of Europe; it frequents the woods, and feeds upon squirrels, mice, and birds. 7. The *putorius*, or pole-cat, has unconnected toes, is of a dirty yellow colour, with a white mouth and ears. This animal is very destructive to birds and poultry. He conceals himself during the day; but steals into barns, dove-cotes, hen houses, &c. in the night, in order to catch his prey. He is a native of most parts of Europe. 8. The *furo*, or ferret, has red eyes, and unconnected toes. This animal is easily tamed, and frequently employed to hunt rabbits out of their holes. The female is less than the male, and brings forth twice in the year, 5 or 6 at a litter. It is a native of Africa. 9. The *zibellina* has divided toes; the body is of a dusky yellow colour, with a white forehead, and an ash-coloured throat. It is found in Tartary, and the northern parts of Asia. 10. The *erminea* has divided toes; and the point of the tail is red. The skin of this animal is a valuable fur, and of a fine white colour. It is a native both of Europe and Asia, and particularly of the northern climates. It feeds upon mice, eggs, &c. and has a very offensive smell. 12. The *nivalis* has divided toes, and a white body. It is very similar to the ermine, but about one half less in size. It is found in Russia and the northern parts of Europe. See Plate CV. fig. 3. and Plate CVI. fig. 1, 2, 3, 4.

MUTE, in a general sense, signifies a person that cannot speak, or has not the use of speech.

MUTE, in grammar, a letter which yields no sound without the addition of a vowel. The simple consonants are ordinarily distinguished into mutes and liquids or semi vowels,

MUTILATION, the retrenching or cutting away any member of the body.

MUTILATION, in Scots law. See LAW, Tit. xxxiii.

MUTULE, in architecture, a kind of square modillion set under the cornice of the Doric order.

MUTUUM, or LOAN, in Scots Law. See LAW, Tit. xx. 7.

MUZZLE of a gun or mortar, the extremity at which the powder and ball is put in; and hence, the muzzling is the metalline circle, or moulding, that surrounds the mouth of the piece.

MYAGRUM, in botany, a genus of the tetrandria filiculosa class. The pod is terminated with a conical stylos, and generally contains but one seed. There are nine species, only one of which, *viz.* the *sativum*, or gold of pleasure, is a native of Britain.

MYCONE, one of the islands of the Archipelago, about twenty five miles in circumference, situated in E long. 25° 6', N. lat. 37°.

MYOLOGLOSSUM, in anatomy. See ANATOMY, p. 304.

MYLOHYOIDÆUS, in anatomy. See ANATOMY, p. 304.

MYOLOGY, that part of anatomy which treats of the muscles of the human body. See ANATOMY, Part II.

MYOPIA, short-sightedness, a species of vision, wherein objects are seen distinctly only at small distances. See OPTICS.

MYOSOTIS, in botany, a genus of the pentandria monogynia class. The corollary consists of 5 emarginated segments. There are four species, only one of which, *viz.* the *scorpioides*, or mouse-ear scorpion-grass, is a native of Britain.

MYOSURUS, in botany, a genus of the pentandria polygynia class. The calix consists of five leaves connected at the base; it has five subulated, petal-shaped nectaria; and the seeds are numerous. There is but one species, *viz.* the *minimus*, or mouse-tail, a native of Britain.

MYRIAD, a term sometimes used to denote ten thousand.

MYRICA, in botany, a genus of the diœcia tetrandria class. The amentum of the male has a lunulated scale; the corolla is wanting both in the male and female; the female has two styli; and the berry contains only one seed. There are five species, none of them natives of Britain.

MYRIOPHYLLUM, in botany, a genus of the monœcia polyandria class. The calix of both male and female consists of four leaves, and none of them have any corolla: the male has eight stamina, and the female four pistilla; and there are four naked seeds. There are two species, both natives of Britain, *viz.* the *spicatum*, or spiked water-millfoil; and the *verticillatum*, or verticillated mill-foil.

MYRMECOPHAGA, in zoology, a genus of quadrupeds belonging to the order of bruta; the characters of which are these: There are no teeth in the mouth; the tongue is long and cylindrical; the head terminates in a long snout or muzzle; and the body is covered

with

with pretty long hair. There are 4 species, viz. 1. The didactyla, or white American coat of Seba, has two toes on the fore feet and four on the hind feet. This animal is about 7 inches long; the head is two inches in length; the snout is not so long as that of the other species; the tail is about an inch longer than the body, and covered with pretty long hair; the legs are not made for walking, but jumping. He climbs trees, and hangs on the branches by the extremity of his tail. In this situation he thrusts his long tongue in the holes or fissures of trees, and brings it out covered with ants or other insects. He can live long without nourishment of any kind, sleeps generally in the day, and searches for food in the night. 2. The tridactyla, tamandua-guaca, or tamaro, has three toes on the fore-feet, and five on the hind-feet, and long hair on the tail. This animal is about four feet long, and the head and snout about fifteen inches: It is a native of the East Indies, and feeds upon ants, &c. in the same manner as the didactyla. See Plate CXVI. fig. 4.—3. The jubata, has four toes on the forefeet and five on the hind ones, and a very hairy tail. This animal resembles the tridactyla, and is found at the Cape of Good Hope. 4. The tetradactyla, has four toes on the fore feet and five on the hind, with a tail naked at the extremity. It is a native of South America.

MYROBALANS, a kind of medicinal fruit brought from the Indies, of which there are five kinds: 1. The citrine, of a yellowish-red, hard, oblong, and the size of an olive: 2. The black, or Indian myrobalan, of the bigness of an acorn, wrinkled, and without a stone: 3. Chebulic myrobalans, which are of the size of a date, pointed at the end, and of a yellowish brown. 4. Emblic, which are round, rough, the size of a gall, and a dark-brown: and, 5. Belleric, which are hard, round, of the size of an ordinary prune, less angular than the rest, and yellow. Each of these kinds are slightly purgative and astringent; but Quincy observes, that the best of them are not worth regarding, since they rather clog than assist any composition.

MYRRH, a vegetable production of the gum or resin kind, issuing by incision, and sometimes spontaneously, from the trunk and larger branches of a tree growing in Egypt, Arabia, and Abyssinia. The incisions are made twice a-year, and the myrrh oozing out is received on rush mats dispersed underneath.

Myrrh is sent over to us in loofe granules of various sizes, from that of a pepper-corn, to the bigness of a walnut. The generality of them, however, are from the size of a pea, to a little more than that of a horse-bean: these are sometimes roundish, but often irregularly long and contorted. The colour of myrrh is a reddish-brown, with more or less of an admixture of yellow, and in the purest pieces it is somewhat transparent. Its taste is bitter and acrid, with a peculiar aromatic flavour, but very nauseous: but its smell, though strong, is not disagreeable. It is to be chosen in clear pieces, light, friable, and of the bitterest taste. Myrrh is of great use in medicine; it powerfully resolves and attenuates thick and viscid blood, and concretion bile, and glutinous humours, and is good in ob-

structions of the menfes, and in infarctions of the viscera.

MYRSINE, in botany, a genus of the pentandria monogynia class. The corolla consists of five segments; and the berry has five cells and five seeds. There is but one species, a native of Æthiopia.

MYRTIFORM, in anatomy, an appellation given to several parts, from their resembling myrtle-berries.

MYRTLE, in botany. See MYRTUS.

MYRTUS, the MYRTLE, in botany, a genus of the icosaandria monogynia class. The calix consists of five segments, and the corolla of five petals; and the berry contains two or three seeds. There are 13 species, none of them natives of Britain.

MYSIA, the ancient name of a province in Asia, being the north-west part of Natolia or Asia Minor.

MYTHOLOGY. The word *mythology* is a Greek compound, that signifies *a discourse on fables*; and comprehends, in a collective sense, all the fabulous and poetic history of pagan antiquity. It follows therefore, that this science teaches the history of the gods, demi gods, and fabulous heroes of antiquity; the theology of the pagans, the principles of their religion, their mysteries, metamorphoses, oracles, &c. By this definition, it appears sufficiently what are the objects of which we are to treat in this article.

If we well consider the matter, we shall find, that there were, in pagan antiquity, three different religions. First, That of the philosophers, who treated metaphysically of the nature, the attributes, and of the works of the Supreme Being. They endeavoured to discover the true God, and the manner in which he ought to be worshipped. It is not wonderful, that these men of exalted genius should in some degree ridicule, in their works, the two other positive religions, and those gods on whom they were founded; at the same time that they outwardly professed the established religion, in order to preserve the peace of society, and to avoid the persecutions of the legislature, and the insults of the populace. For in fact, was it possible for them to believe the pagan fables? Must they not foresee, that their religion would one day give place to another, while their own works would pass with their names to the latest posterity? And could they suffer the thought, that their reputation would be tarnished in the eyes of that posterity, by having it imagined they believed such idle tales as were broached by the priests of their times? Could Plato, Socrates, Seneca, and Cicero, be unconcerned for their fame among future generations, and future philosophers? And what should we at this day have said of those great men, had they been so political, or hypocritical, as to have entirely concealed their sentiments with regard to these matters?

The second religion was that of paganism, which was the established religion of all the ancient nations except the Jews. This was the doctrine that was taught by the priests, and protected by the sovereigns. Its dogmas were demonstratively false, but not always so absurd as may at first appear, especially if we annex to the divinities, and to the religious ceremonies of the pagans, a sense that is frequently mystic, and always allegoric; if we remember,

that the first heathens deified those great men to whom the rest of mankind were indebted for any signal benefits, as Jupiter, Apollo, Ceres, Bacchus, Hercules, Æsculapius, &c. in order to induce others, as well of the present as future ages, to reverence and to imitate them. Would not an ancient pagan, if he were to return upon the earth, have specious arguments, at least, to support his religion, when he saw weak mortals beatify or canonize, merely by their own authority, other weak mortals (frequently mere pedants,) and place them in heaven, without the permission or approbation of the Supreme Being? Happy is it for mankind, when at different times sagacious pontiffs purge the calendar, and the brains of the people, from a herd of pretended saints, and prevent them, at least after their death, from doing injury to society, by interrupting the industry of the laborious inhabitants with keeping their festivals.

The third religion was idolatry, or the religion of the populace. For the common people, born to be deceived in every thing, confounding in their imaginations the statues of the gods, the idols of their divinities, the emblems of their virtues and of religious worship, with the gods, divinities, virtues and worship themselves, adored these images, and proceeded to extravagancies the most ridiculous, and frequently most criminal, in their ceremonies, feasts, libations, sacrifices, &c. It is to be feared, that, as long as there are upon the earth men of our limited capacities, this triple religion will constantly subsist under different forms; and we are much deceived, if it may not be found under the empire of Christianity itself, notwithstanding the purity of its doctrine. It will be easily conceived, that it is not of the religion of philosophers, nor that of the populace, of which we are to treat in this article of Mythology; but of that which subsisted under the authority of the magistracy and the priesthood, and consequently of paganism in general.

As far as we are able to judge by all the ancient authors we have read, the pagans adored the sovereign Lord of the universe under the name of *Fate* or *Destiny*, which we must not confound with *Fortune*, who was regarded as a subaltern divinity. Jupiter himself, all the gods, every animated being, the heavens, the earth, the whole frame of nature, was subservient to *Destiny*, and nothing could reverse its decrees. This divinity was so highly adorable, as to be above all rank; and was regarded as too supreme to be represented under any sensible image or statue, or to have any temple erected for its worship. We do not remember to have read, that any sacrifice was ever offered to this *Destiny*, or that any temple or city was ever dedicated to its name. We are almost inclined to think, that the pagans were sensible, that the temple and the worship of the God of gods ought to be in the heart of man. Mention is made, indeed, of a temple that was dedicated to the Unknown God, but we are ignorant whether or not *Destiny* were thereby meant. We must not confound this *Destiny*, moreover, with the goddesses of chance, of which there are some antique statues that represent her in a recumbent posture, and playing with little bones; for this was nothing more than an invention of some statuary.

After this general and philosophical idea of the Sa-

preme Being, comes the positive religion of the pagans. This was entirely founded on fable, which took its rise either from ancient traditions, or historical events, altered or augmented by the imaginations of the poets, by superstition, or by the credulity of the people; or else it consisted of allegoric or moral fictions. A crowd of writers, and among the rest *Néel le Comte*, (Natalis Comes,) the abbots *Bannier* and *Pluche*, &c. have made many researches into the origin of fable: and they think they have discovered its source, 1. in the vanity of mankind; 2. in the want of letters and characters; 3. in the delusive eloquence of orators; 4. in the relations of travellers; 5. in the fictions of poets, painters, statuary, and dramatic writers; 6. in the diversity and uniformity of names; 7. in the ignorance of true philosophy; 8. in the foundation of colonies, and the invention of arts; 9. in the desire of having gods for our ancestors; 10. in the imperfect or false interpretation of the holy scriptures; 11. in the ignorance of ancient history; 12. in a like ignorance of chronology; 13. in that of foreign languages; 14. in the translation of the religion of the Egyptians and Phœnicians into Greece; 15. in the ignorance of geography; and, 16. in the belief that the first people had of the intercourse of gods with men. It is certain, that all these matters taken together are sufficient to produce many thousands of fables; are more than sufficient to enable us to deceive ourselves and others, and to give rise to infinite reveries. But we should take care how we draw from these sources demonstrations that might be used, by infidels, as arguments to overthrow the history of the Jews; a people the most stupid, most credulous, and ostentatious of all others! In the mean time, the pagan philosophers themselves asserted, that it was a god who invented the fable: so much they were convinced of its ingenuity, and of its strong tendency to instruct mankind in their duty.

Mythology therefore, when properly treated, begins with making learned researches into the real origin of fable, of paganism, and of that idolatry which was its consequence. It recurs for this purpose even to the beginning of the world: and after finding that *Laban*, the father-in-law of the patriarch *Jacob*, was a maker of idols; and that he had his little images, or household gods, which he formed of baked earth, and which shews that idolatry existed in the greatest antiquity; it then explains *cosmogony*, and *theogony*, or the belief that the first inhabitants of the earth entertained of the creation of the universe, and what the pagan theology taught of the genealogy of their false gods. It begins with the tradition of the Chaldeans, a people so ancient, that *Nimrod* was their first king; but at the same time so credulous and superstitious, that we may regard them as the authors of all those fables, and the propagators of all those visions, that have since blinded human reason. According to this tradition, a monster named *Oannes*, or *Oes*, half fish and half man, sprang from the sea, before the chaos was completely dispersed, and gave laws to the Chaldeans. A woman called *Omorka*, reigned over all the earth. *Bel* cut her in two, and made of one moiety the heavens, and of the other the earth. They likewise invented the two primitive beings, of which the good one, who was named *Orasmajdes*, had the direction

tion of heaven; and the other, called *Arimanius*, that of hell.

The science of mythology then teaches the theogony of the Phœnicians; concerning whom it draws great lights from Sanchoniathon, a priest of Beryte, who lived before the Trojan wars, more than four hundred years before Hesiod and Homer, and of whom Eusebius has preserved considerable fragments. From thence it passes to the theogony of the Egyptians; of whom *Thot* or *Thaut*, the founder of that nation, was likewise, they say, their first historian; that Sanchoniathon even copied from him; and of whom we find many relations in the Greek historians, especially in Herodotus, Diodorus Siculus, and in Eusebius of Cæsarea. It then examines the theogony of the Atlantides, who dwelt on the western part of Africa, and of whom Diodorus alone has preserved any account. From thence it proceeds to the theogony of the Greeks, which is far better known to us, as we find accounts of it, more or less particular, in numberless Greek and Latin writers. This theogony had the same foundation as that of the Romans; the latter having only extended it, by adding to the Greek divinities certain gods or demigods, formed of their heroes, and certain symbolic and allegoric divinities, which mythology explains at the same time: and it is on this occasion that it enters into a particular explication of the cosmogony and theogony of *Ovid*; whose book of metamorphoses contains as copious descriptions as we could desire of the fables of the ancients: what was their belief concerning the habitations of the blessed after their death, or of the Elysian fields; as well as of their hell or tartarus; of the dog Cerberus; of the ferryman Charon; of the furies; of the four rivers, Cocytus, Lethe, Phlegethon, and Styx, which water the tartarian regions, &c. The learned have likewise made many inquiries, and many ingenious discoveries, concerning the theogony of the ancient Germans, Celts, the Scythian and Hyperborean nation. In the last place, this science furnishes great lights on the theogony of the Bramins, the Troglodytes, the Indians, the Chinese, and even the Americans; all which it concludes with a regular and minute examination of the pagan theology, and particularly that of the poets.

All these matters being well digested in the minds of those who would make a regular study of pagan theology, they continue their researches into the time, the epoch and place of the real origin of paganism and idolatry; and they prove that the pagans began by adoring the heavenly bodies, the stars and planets. They next examine into the progress of idolatry: what were the temples of the pagans, their altars, their inclosures, their sacred groves, their asylums, the idols and statutes of their deities; in what manner they were represented; what were their sacrifices, the victims that were offered; what were the sacred vessels, the censers and other instruments that were used in the sacrifices, libations, and other religious ceremonies: concerning the priests, priestesses, and other attendants on the service of each divinity: what were the festivals that were celebrated among the Greeks and Romans, as well as among the orientals; what the days of penitence and supplication, the feasts or the gods of *lectisternia*, their invocations or incantations, and exorcisms,

the religious ceremonies observed at laying the foundations of cities, &c.

Divination, or the prediction of future events, a weakness that has at all times possessed the human mind, forms also an important article of pagan theology. It is therefore in this place, that mythology considers the nature of *Oracles*; and in particular, 1. The oracle of Dodono, the most ancient of Greece; 2. That of Jupiter, Hammon or Ammon, in Libya; 3. That of Jupiter Philius; 4. That of Apollo, both of Heliopolis; 5. That of Apollo of Delphos; 6. That of Trophonius in Boeotia; 7. That of Venus of Aphaca, a country between Byblos and Heliopolis, situate on a small lake; and a great number of other oracles of less note, dispersed over Greece and other countries. It also examines in what manner these oracles gave their answers, the ceremonies that were observed in consulting them, the frantic emotions of the priestless Pythia on her tripod; and those of other priests. It then endeavours to determine if there ever were in fact any Sibyls, which, whatever has been said, is still very doubtful; it draws, however, from all the sources of antiquity, a kind of history of these Sibyls, and of their prophecies. It next passes to the examen of the nature of auguries, auspices, haruspices, presages, prodigies, and phenomena, of expiations and ablutions, of the magic and astrology of the ancients, &c. Whoever has thoroughly studied all these objects, is fully provided with the preliminary knowledge that is necessary to enable him to proceed steadily and securely through the darkness of ancient mythology, and he may thereby advance more confidently to the examination of the nature of the pagan divinities themselves.

The celebrated treatise of Cicero *De natura Deorum* will here furnish great lights: but modern authors who have treated on these matters, have not been contented with this alone: they have, so to say, extracted the essence of all antiquity, of which they have formed systems; but unluckily these scarce ever agree with each other. As philosophers, it is of very little importance for us to know what was the nature of these gods, seeing we know that they were merely fabulous: but as historians and antiquaries, it concerns us to know what was the nature that was attributed to them in general; and, in particular, what were the origin, genealogy, rank, functions, authority, and operations, that were attributed to each divinity; and it is on these matters that we have still some remarks to make.

The gods of the ancient Greeks and Romans were all either *Dii majorum gentium*, or *Dii minorum gentium*; that is, of the first or second order. The former were also called *consentes*, *magni consultores*, &c. According to Ennius they were twelve in number, and are included in these verses:

Juno, Vesta, Minerva, Ceres, Diana, Venus, Mars, Mercurius, Jovis, Neptunus, Vulcanus, Apollo.

To these were added eight others under the title of *selesti*, which were Sol, Luna, Tellus, Genius, Janus, Saturnus, Liber, and Pluto. The second order, or *minorum gentium*, were called Adscriptitii, Medioximi, Manuscularii, Putatitii, Indigetes, Semones, &c. the principal of which were Æsculapius, Bacchus, Castor, Fauna, Hercules,

Iles, the Lares or Penates, Pollux, Quirinus, Semo Sancus or Dius Fidius, &c.

According to the second division, all their divinities were classed into, 1. Celestial gods, 2. Terrestrial gods, 3. Sea gods, and 4. The Infernal deities, or *inferi*. The celestial gods were Jupiter, Juno, Apollo, Aurora, Cupid, Cybele, the Graces, Hebe, Iris, Luna, Mars, Mercury, Minerva, Nemesis, Saturn, Themis, Venus, &c. The terrestrial gods were Æolus, Astræus, Astræa, Ceres, Diana, the Fauni, Feronia, Flora, Janus, Momus, the Muses, Pales, Pan, Pomona, Priapus, the Satyrs, Silenus, Silvanus, the god Terminus, Vesta or Rhea, Berecynthia, Vulcan, Harpocrates, &c. The sea-gods were Neptune, Amphitrite, Thetis, Canopus, Glaucus, Ino, the Nereids, Nereus, Oceanus, Palæmon, Triton, &c. The infernal gods were Pluto, Proserpine, Charon, Minos, Æacus, Rhadamanthus, the Furies, Death, Night, the Fates, Pluto, &c.

The third division ranged the divinities according as they presided, 1. Over the pregnancy of women (*Pregnantium*); 2. At parturitions (*Parturientium*); 3. At births (*Nascentium*); 4. At adulteries; 5. At marriages: To which they added, 7. Dii morales, or moral gods; and 7. Funeral gods. The gods of pregnancy were Pilumnus, Intercidona, and Deverra: the gods of parturition, Juno, Lucina, Diana, Egerio, Profa, Poliverta, Menagenata, Latona, the gods that were called Nixi, or of labour, &c. The gods of birth were Janus, Opis, Nascion, Cunina, Carmenta, Vaginianus, Laverna, Rumia, Potina, Educa, Ollago, Carne, Nundina, Statilius, Fabulinus, Pavenia, &c. The gods of adultery were Juventus, Agenoria, Strenua, Stimula, Horta, Quies, Murcia, Adeona, Abeona, Voluptas, Orbona, Pellonia, Numeria, Camoena, Sentia, Angerona, Heres, Martea, Laverna, the god Averruncus, Confus, Catius, Volumus and Volumna, Honorius, Aius Locutius, &c. The nuptial gods were Diana, Domiduca, Domitius, Hymenzus or Hymen, Jugatinus, Jupiter perfectus, Juno perfecta, Juno cinxia, Juna unxia, Lucina, Manturna, Mutinus, Dea Mater prima, Suada, Thalassius, Venus, &c. The moral gods were called Virtus, Honor, Fides, Spes, Justitia, Pietas, Misericordia, Clementia, Pudicitia, Veritas, Mens, Concordia, Pax, Salus, Felicitas, Libertas, Pecunia, Ritus, Invidia, Contumelia, Impudentia, Calumnia, Fraus, Discordia, Furor, Fama, Fortuna, with all their epithets good or bad, Febris, Pavor and Palor, Paupertas, Nec sitis, Tempestas, Silentium, &c. The funeral gods were Pluto, Libitina, Nænia, Death, the Fates, &c.

Hesiod indeed pretends that all these gods derived their origin from chaos; but we have already pointed out more just sources. It is almost incredible to what a prodigious number the superstition and weakness of the Greeks and Romans multiplied these divinities: there have been thirty thousand of them enumerated. It will not be expected that we should here attempt to describe them, nor will it be remarkable if we have forgot to mention even some of the first rank: Although, vast as this company of gods is, mythology does not omit to trace the history of the greatest part of them, as is taught by paganism; and they who are desirous of particular information in these mat-

ters may consult with advantage the theology of Hesiod, the catalogue of Apollodorus, the metamorphoses of Ovid, the fables of Hygine, Lylii Gregorii Gyraldi Syntagma de Diis Gentilium, the mythology of Natalis Comes, the books of Gerard Vossius de Idolatria Gentilium, Johannis Boccatii Genealogia Deorum, the Pantheon of Pomey, the history of heaven by Abbe Pluche, the historical explanation of fables by Abbe Banier, and numberless other works of the same kind in all languages.

There were still many other distinctions, of which the pagans made use to mark the rank, the functions and nature of their several divinities. For example, the goddess Vesta, or the mother of all the gods, was adored by all people in general. Mars, Bellona, Victoria, Fortunata, &c. assisted all parties. The topical gods, on the contrary, were adored in particular countries only; as Astarte in Syria, Derceto and Semiramis among the Assyrians, Isis and Osiris by the Egyptians, Quirinus at Rome, &c. The title Semones, which was given to a certain class of divinities, was doubtless derived from Semi homines, that is, demi-men; and signified the same as semi-dii, or demi-gods. These were monarchs and illustrious heroes, or those great men who were the founders of cities and nations, that were deified by way of apotheosis. Pythagoras had taught the Chaldeans the doctrine of transmigration; and that, after their death, those who were virtuous would be elevated to the rank of divinities. This doctrine was adopted by all the pagan world. The apotheosis, after they had erected temples and altars to the new gods, was celebrated with much solemnity. In the last ceremony, an eagle was fixed on the catafalk, or funeral pile, on which was placed the image of the hero; and when the pile began to burn, the eagle was let loose, who, mounting into the air with the flames, seemed to carry the soul of the departed hero up to heaven.

Mythology informs us also, who those persons were that antiquity regarded as the children of the gods, such as Theseus, Hippolytus, Paris, &c.; what the pagans believed with regard to the nature of their Genii and Demons, of their Dryades, Hamadryades, Nymphs, Tritons, Sirens, Fauns, Sylans, Centaurs, and other subaltern divinities; and in this manner it explains all the systems of the positive religion of the Greeks and Romans. They who are desirous of extending their knowledge of paganism still further, of knowing the dogmas of each particular people; what were their gods, and the various manners in which they were worshipped, such as Apis, Isis, Osiris, &c. the adoration of crocodiles and onions, &c. among the Egyptians, must study the different theologies of these people; and notwithstanding all the informations which ancient and modern authors afford, this study is yet boundless, and attended with many difficulties and uncertainties: Though it appears demonstrative, that the origin of paganism, and of idolatry in general, was derived from the Chaldeans, from whom the Egyptians drew that doctrine which they after transmitted to all other nations; and consequently that the primordial divinities were the same, under different denominations, among all the idolatrous nations of the earth.

The nature of this work will not permit us to descend to further particulars. But to give our readers an idea of

of the manner in which mythology treats its subjects, and of the method that should be observed in studying fable, or the history of the gods of antiquity, we shall here give, by way of example, a carfory description of Parnassus and its inhabitants.

Parnassus was a mountain of Phocis, that had two summits, one of which was called Tithoreus, and the other Hyampeus. Others say, that one of these hills was named Helicon; and the other Cytheron; and that it is an error to imagine, that Helicon was a mountain of Boeotia. However that be, this double hill was consecrated to Apollo and the Muses, who there held their usual residence. According to fable, there had been a remarkable combat on this hill, between Helicon and Cytheron. Whoever slept on Parnassus, when he waked became a poet. Apollo had there a temple. There also was the fountain Castalia, into which Apollo had metamorphosed a nymph that he loved, and had given to its waters the power of making all who drank of them poets. At the foot of Parnassus flowed the river Hippocrene, that had the same virtue; and the source of which was opened by a stroke of the foot of the horse Pegasus. This river nourished a great number of swans, that were regarded as sacred. Pegasus was a winged horse, that belonged to Apollo, and grazed on the summit of Parnassus. He sprang from the blood of Medusa, when Perseus cut off her head, which was placed among the stars. Such was the delicious abode of Apollo, the son of Jupiter and Latona, who was born, with his twin sister Diana, in the island Delos. He killed the Cyclops, who forged the thunderbolts with which Jupiter had overthrown his son Æsculapius; but for that presumption, he was forced to leave heaven, and become an inhabitant of the earth. He guarded the oxen of Admetus; he aided Neptune to build the walls of Troy, and Alceus in forming the labyrinth. He killed the dragon or serpent Python. He invented, Music and physick; and was honoured as the god of poets and physicians. He was represented as a young man without a beard, his head surrounded with rays, and bearing in his hand a bow, or a lyre. As the ancients denoted the sun by the name of Apollo, they sometimes represented him also as seated in a chariot, drawn by two white horses, preceded by Aurora and the star Venus: Phaeton his son, being desirous of conducting these horses, was thrown into the sea. Apollo was also called Phœbus, Titan, and Sol. He is known to have had amours with Arctinoë, Corycia, Melcene, Cyrene, Mantho, Sinope, Calliope, and others; by whom he had Delphæ, Naxos, Miletus, Arabe, Garamas, Sirius, Linus, Orpheus, and other children. He had peculiar honours paid him in the Pythian games at Delphos, and in the secular games at Rome.

The Muses were the companions of Apollo in his rural abode. They were likewise called the learned sisters; as also the Camœnian, Heliconian, Parnassian, Aonian, Pierian, Pegasus, Aganippian, Thespian, Libethrian, and Castalian sisters. They were the daughters of Jupiter and Mnemosyne, and were regarded as the goddesses of Sciences and arts in general. There were nine of these

muses; to whom they attributed, 1. to Clio, history, 2. to Melpomene, tragedy, 3. to Thalia, comedy, 4. to Euterpe, flutes and other pneumatic instruments of music, 5. to Terpsichore, the harp and the dance, 6. to Erato, the lyre and the lute, 7. to Calliope, heroic verse, 8. to Urania, astronomy, and 9. to Polyhymnia, rhetoric and eloquence. The Graces also sometimes quitted Venus to pay their court to Apollo.

Such was the idea they entertained of Parnassus and its inhabitants. There is no doubt but that, under these fabulous representations, these sensible images, were concealed allegoric and moral meanings; nor can it be denied but that their method of cultivating the arts and sciences, by this manner of expressing their ideas, was as ingenious and pleasing as it is possible to imagine. Every other subject that paganism embraced, it treated with the same genius, and in a manner equally pleasing; and though that religion was altogether fallacious, yet we must allow that it was extremely well calculated to promote the polite arts, by those refined, noble, graceful, brilliant images, by those charming subjects, which it constantly presented, and which it still offers to the poet, painter, sculptor, and every other artist.

But this was not a power sufficiently strong to secure paganism against that vicissitude, that decline and dissolution, which finally attends all the productions of this world. This religion, which had subsisted near five thousand years, and almost from the origin of the human race, gradually declined in proportion as the lights of Christianity and philosophy illumined the minds of mankind. For though the pagan religion, and the fables on which it was founded, were pleasing and favourable to the polite arts, they were not however calculated to satisfy the minds of philosophers, nor to promote the real good of mankind, by securing their temporal and eternal happiness. It is even surprising that so great a genius as the emperor Julian should attempt to revive the embers of paganism, which insensibly declined, and had received a mortal blow at the beginning of the fourth century by the emperor Constantine the great. Julian employed all the resources of his imagination, of his eloquence, of his power, and even of his own fatal example, to revive it; but in vain. The fatal period of paganism was arrived, and nothing could save it from destruction. The furious Theodosius, to whom bigotted priests and historians have assigned the name of Great, totally overthrew it toward the close of the same century, destroyed those temples and altars which yet subsisted, dispersed its colleges, and exterminated its priests. From that dire epoch, nothing of paganism has remained, except some ruins dispersed in the remote parts of the earth, and among people wretched and almost unknown; where this religion, once so flourishing and universal, is now degenerated into gross and disgusting idolatry.

MYURUS, in medicine, an epithet for a sort of sinking pulse, when the second stroke is less than the first, the third than the second, and so on.

N.

N A M

NAROB, a viceroy or governor of one of the provinces of the Mogul's empire, in India.

NABONASSAR, or *Æra of NABONASSAR*. See *ASTRONOMY*, p. 493.

NADIR, in astronomy, that point of the heavens which is diametrically opposite to the zenith, or point directly over our heads. See *ASTRONOMY*, p. 435.

NÆVI, in surgery, marks or excrescences made on the skin of an infant before its birth, vulgarly supposed to be occasioned by the imagination of the mother.

NAHUM, or *the prophecy of NAHUM*, a canonical book of the Old Testament.

Nahum, the seventh of the twelve lesser prophets, was a native of Elko-hai, a little village of Galilee. The subject of his prophecy is the destruction of Nineveh, which he describes in the most lively and pathetic manner; his style is bold and figurative, and cannot be exceeded by the most perfect masters of oratory. This prophecy was verified at the siege of that city by Assyges, in the year of the world 3378, 622 years before Christ.

NAIADS, in mythology, the nymphs of the fountains. See *MYTHOLOGY*.

NAIANT, in heraldry, a term used in blazoning fishes, when borne in an horizontal posture, as if swimming.

NAJAS, in botany, a genus of the monœcia monandria class. The calix of the male is cylindrical and bifid; the corolla consists of four segments; and there are no filaments: The female has neither calix nor corolla, but one pistil and an ovated capsule. There is only one species, *viz.* the marina, found in the European seas.

NAIL, *unguis*, in anatomy. See *ANATOMY*, p. 256.

NAILS, in building, &c. small spikes of iron, brass, &c. which being drove into wood, serve to bind several pieces together, or to fasten something upon them.

NAIL, is also a measure of length, containing the sixteenth part of a yard.

NAIRN, a borough and port town of Scotland, eighteen miles east of the town of Inverness.

NAISSANT, in heraldry, is applied to any animal issuing out of the midst of some ordinary, and shewing only his head, shoulders, forefeet and legs, with the tip of his tail; the rest of his body being hid in the shield, or some charge upon it; in which it differs from issuant, which denotes a living creature arising out of the bottom of any ordinary or charge.

NAKED SEEDS, in botany, are those that are not inclosed in any pod or case.

NAMA, in botany, a genus of the pentandria digynia class. The calix consists of five leaves, and the corol-

la of five segments; and the capsule has one cell and two valves. There are two species, none of them natives of Britain.

NAME, denotes a word whereby men have agreed to express some idea; or which serves to signify a thing or subject spoken of. See *GRAMMAR*.

NAMUR, a strong city of the Austrian Netherlands, capital of the province of Namur, situated at the confluence of the Sambre and Maese: E. long. 4° 50', N. lat. 50° 30'.

NANCY, the capital of Lorraine in Germany, situated in E. long. 6°, N. lat. 48° 44'.

NANFIO, one of the islands in the Archipelago, sixteen miles round, and situated in E. long. 26°, N. lat. 35°.

NANKING, the capital of the province of Nanking, and formerly of the Empire of China, is situated in E. long. 118° 30', N. lat. 32°.

NANSAMUND, a county of Virginia, in North America, south of the Isle of Wight county, through which the river of Nansamund runs.

NANTZ, a city of France in the province of Brittany, situated on the river Loire, in W. long. 1° 30', N. lat. 47° 15'.

NANTWICH, a market town of Cheshire, situated seventeen miles south-west of Chester.

NAP/EA, in botany, a genus of the monadelphia polyandria class. The calix is simple and cylindrical; and the capsule contains one seed. There are two species, none of them natives of Britain.

NAPHTHA, in natural history, a fluid mineral body, of a thin consistence, bright and pellucid, of a strong smell, very readily inflammable, and, when pure, burning away without leaving any residuum.

The naphtha is found in considerable quantities floating on the water of certain springs, principally breaking out at the sides of hills in Persia, Tartary, and some parts of the empire of China; where if a lighted candle be held near the surface, it takes fire and overpreads the surface of the water for a great extent, with a strong white flame, and emits a very disagreeable smell. The genuine naphtha is very rare in Europe; it is not known to be any where naturally produced here, and what we see of it is generally sophisticated. Distilled by the retort, it yields an oil somewhat thinner than it was originally, and of a weaker smell. The substance remaining at the bottom of the retort, has much the resemblance of amber; and Dr Hill thinks it highly probable, that the origin of all the amber is from the same sort of principle; nay, he tells us that he has succeeded

N A P

ceeded so far in an attempt to make amber by this fluid and an acid drawn from the crude pyrites, that he has produced a friable somewhat pellucid matter, having all the properties of amber except its hardness and cleanness, and yielding a true salt and oil of amber on distillation.

The medicinal virtues of the naphtha are the same with the common petroleum, but in a more remiss degree. It is used externally on many occasions in Persia; and is taken inwardly, a few drops for a dose, in colics. The principal use made of it, however, is burning in lamps, for which purpose it is very proper.

NAPIER's, or NEPER's BONES. See **NEPER**.

NAPLES, the capital of the kingdom of Naples: situated in E. long. 15°, N. lat. 41°.

The kingdom of Naples is one of the Sicilies; it is the south-east part of Italy, and is situated between 14° and 19° E. long. and between 38 and 34° N. lat. being bounded by the gulph of Venice on the north-east, by the Mediterranean sea on the south-east, by Sicily and the Tuscan sea on the south-west, and by the Pope's territories on the north-west; and divided from the islands of Sicily only by the narrow strait of Pharo or Messina.

NARBARTH, a town of Pembrokeshire, in south Wales, situated ten miles north east of Pembroke.

NARBONNE, a city of France, in the province of Languedoc: situated in E. long. 2° 40', N. lat. 43° 18'.

NARBOROUGH, an island of South-America, in the Pacific Ocean, situated on the coast of Chili, in W. long. 85°, S. lat. 45°.

NARCISSUS, the **DAFFODIL**, in botany, a genus of the hexandria monogynia class. The corolla consists of six leaves, and the nectarium of one entire funnel-shaped leaf; and the stamina are situate within the nectarium. There are 13 species, only two of which are natives of Britain, viz. the poeticus, common pale daffodil, or primrose peerless; and the pseudo-narcissus, or wild English daffodil.

NARCOTICS, in medicine, soporiferous medicines, which excite a stupefaction.

Narcotics, called also hypnotics, anodynes, or stupefactive, are said, by Hoffman, to be such kind of remedies as, by their subtle, noxious, and deleterious exhalations, diminish, or quite destroy, the sense and motion of the solid parts. Among narcotics, the most eminent are those which are usually prepared for medicinal uses of the whole poppy, especially opium; as also all those prepared of mandragoras, hyoscyamus, stramonium, and datura.

NARDO, a port town of Italy, in the kingdom of Naples: E. long. 19°, N. lat. 40° 33'.

NARDUS, in botany, a genus of the triandria monogynia class. It has no calix, and the corolla consists of two valves. There are five species, only one of which, viz. the sticta, or malt-grass is a native of Britain.

NARRATION, in oratory and history, a recital or rehearsal of a fact as it happened, or when it is supposed to have happened. See **DESCRIPTION**.

NARWAL, in ichthyology. See **MONODON**,

NARVAR, a city of the hither India, the capital of the province of Narvar: E. long. 79°, N. lat. 25°.

NASIAS, in anatomy, a thin bone, making the upper part of the nose. See **ANATOMY**, p. 160.

NASSAU, the capital of the county of the same name in Germany: E. long. 7° 25', N. lat. 50° 21'.

NASSUS, in ichthyology. See **CYPRINUS**.

NATES, in anatomy, a term expressing those two fleshy exterior parts of the body vulgarly called the buttocks.

NATES CEREBRI. See **ANATOMY**, p. 286.

NATION, a collective term, used for a considerable number of people inhabiting a certain extent of land, confined within fixed limits, and under the same government.

NATIVE, a person considered as born in a certain place which was the proper residence of his parents, and where he received his education.

NATIVITY, or **NATAL DAY**, the day of a person's birth: The word nativity is chiefly used in speaking of the saints, as the nativity of St. John the Baptist, &c. But when we say the Nativity, it is understood of that of Jesus Christ, or the feast of Christmas.

NATOLIA, the modern name of the Lesser Asia, being the most westerly part of Turkey in Asia, and consisting of a large peninsula, which extends from the river Euphrates, as far as the Archipelago, the seas of Marmora, the straits of Galipoli and of Constantinople, which separate it from Europe on the west. It is bounded on the north by the Black-Sea, and on the south by the Mediterranean sea.

NATRIX, in zoology. See **COLUBER**.

NATRUM, the nitre of the ancients, in natural history, is a genuine, pure and native salt, extremely different from our nitre, and indeed from all the other native salts; it being a fixed alkali, plainly of the nature of those made by fire from vegetables, yet capable of a regular crystallization, which those salts are not. It is found on the surface of the earth, or at very small depths within it; and is naturally formed into thin and flat cakes or crusts, which are of a spongy or cavernous substance, very light and friable, and, when pure, of a pale brownish-white; but as its spongy texture renders it very subject to be fouled by earth received into its pores, it is often met with of a deep dirty brown, and not unfrequently reddish.

Natrum, whether native or purified, dissolves in a very small quantity of water; and this solution is, in many parts of Asia, used for washing; where it is also made into soap, by mixing it with oil. Natrum reduced to powder, and mixed with sand or flints, or with any other stone of which crystal is the basis, make them readily run into glass, Gold heated red hot, and sprinkled with a small quantity of this salt, melts immediately; silver ignited and sprinkled with it, melts in the same manner; as does also iron, copper, and the regulus of antimony, which melt much more easily than they otherwise would do. Mercury will not be mixed with it by any art, and indeed will not amalgamate with metals if only a little of this salt be added. It is found in great abundance in many parts of Asia, where the natives sweep

it up from the surface of the ground, and call it soap-earth. The earliest account we have of it is in the Scriptures, where we find that the salt called nitre in those times would ferment with vinegar, and had an absterfve quality, so that it was used in baths and in washing things. Solomon compares the singing of

songs with a heavy heart, to the contrariety of vinegar and nitre; and Jeremiah says, that if the sinner wash himself with nitre, his sin is not cleansed off. These are properties that perfectly agree with this salt, but not at all with our salt petre.

N A T U R A L H I S T O R Y.

NATURAL HISTORY, is that science which not only gives compleat descriptions of natural productions in general, but also teaches the method of arranging them into Classes, Orders, Genera, and Species. This definition includes Zoology, Botany, Mineralogy, &c. But, in a work of this kind, we thought it would be easier, and more advantageous to the reader, to treat these branches of natural history separately under their respective names. See BOTANY, &c. Under the title of NATURAL HISTORY, therefore, we shall confine ourselves to ZOOLOGY, or that part of it which relates to *Animals*. It is likewise necessary to mention in this place, that we have given the descriptions and characters of animals under their proper names. The scientific part of the subject, therefore, or the method of investigating the genera or species of animals, by means of natural or artificial arrangement, only remains to be explained.

In order to abridge the study of zoology, many methods of reducing animals to classes, genera, and species, have been invented. But, as that of Linnæus is undoubtedly the best, the most extensive, and the least understood, we shall give a brief account of it.

Linnæus divides the whole animal kingdom into 6 classes. The characters of these 6 classes are taken from the internal structure of animals, in the following manner.

CLASS I. MAMMALIA, includes all animals that suckle their young. The characters of this class are these:—The heart has two ventricles and two auricles; the blood is red and warm; and the animals belonging to it are *viviparous*.

CLASS II. AVES, or *BIRDS*.—The characters are the same with those of Class I. excepting that the animals belonging to it are *oviparous*.

CLASS III. AMPHIBIA, or *AMPHIBIOUS ANIMALS*.—The heart has but one ventricle and one auricle; the blood is red and cold; and the animals belonging to this class have the command of their *lungs*, so that the intervals between *inspiration* and *expiration* are in some measure *voluntary*.

CLASS IV. PISCES, or *FISHES*.—The heart has the same structure, and the blood the same qualities with those of the *Amphibia*; but the animals belonging to this class are easily distinguished from the *Amphibia*, by having no such voluntary command of their *lungs*, and by having external *branchiæ* or *gills*.

CLASS V. INSECTA, or *INSECTS*.—The heart

has one *ventricle*, but no *auricle*; the blood is cold and white; and the animals are furnished with *antennæ*, or *feelers*.

CLASS VI. VERMES, or *WORMS*.—The characters are the same with those of Class V. only the animals have no antennæ, and are furnished with *tentacula*.

The *First Class*, **MAMMALIA**, is subdivided into 7 **ORDERS**; the characters of which are taken from the number, structure, and situation of the **TEETH**.

ORDER I. The **PRIMATES**, have 4 incisors, or *fore-teeth*, in each jaw, and one *dog-tooth*. N. B. By one *dog-tooth*, Linnæus means one on each side of the *fore-teeth* in both jaws.—This order includes 4 genera, *viz.* Homo, Simia, Lemur, Vespertilio. See these articles.

ORDER II. The **BRUTA**, have no *fore-teeth* in either jaw.—This order includes 6 genera, *viz.* Elephas, Trichechus, Bradypus, Myrmecophaga, Manis, Dasypus. See these articles.

ORDER III. The **FERRÆ**, have, for the most part, 6 *caninal fore-teeth* in each jaw.—This order includes 10 genera, *viz.* Phoca, Canis, Felis, Viverra, Mustela, Ursus, Didelphis, Talpa, Sorex, Erinaceus. See these articles.

ORDER IV. The **GLIRES**, have 2 *fore-teeth* in each jaw, and no *dog-teeth*.—This order includes 6 genera, *viz.* Hylitrix, Lepus, Castor, Mus, Sciurus, Noctilio. See these articles.

ORDER V. The **PERCORA**, have no *fore-teeth* in the upper jaw, but 6 or 8 in the under-jaw.—This order includes 6 genera, *viz.* Camelus, Moschus, Cervus, Capra, Ovis, Bos. See these articles.

ORDER VI. The **BELLUÆ**, have *obtuse fore-teeth* in each jaw.—This order includes 4 genera, *viz.* Equus, Hippopotamus, Sus, Rhinoceros. See these articles.

ORDER VII. The **CETE**, or *whale kind*, have no uniform character in their teeth, being very different in the different genera; but are sufficiently distinguished from the other orders of *Mammalia*, by living in the ocean, having pectoral fins, and a siftna or spiraculum upon the head.—This order includes 4 genera, *viz.* Monodon, Balæna, Physeter, Delphinus. See these articles.

The *generic characters* of the *Mammalia* are, like those of the *orders*, almost entirely taken from the **TEETH**, excepting

excepting the Vespertilio, which, besides the character of the order derived from the teeth, has this further mark, that there is a membrane attached to the feet and sides, by means of which the creature is enabled to fly;—the Hylirix, whose body is covered with sharp spines;—and the whole order of Pecora, whose genera, besides the characters taken from the teeth, are distinguished into those which have horns, those which have no horns, and by peculiarities in the horns themselves.

The specific characters are very various, being taken from any part of the body which possesses a peculiar uniform mark of distinction. As examples of these characters are to be found under the proper name of each genus, it is unnecessary to say any thing further concerning them in this place.

The Second Class, AVES, is subdivided into six Orders, the characters of which are taken chiefly from the structure of the BILL.

ORDER I. The ACCIPITRES, have a HOOKED BILL, the superior mandible, near the base, being extended on each side beyond the inferior; and in some, the superior mandible is armed with teeth. —This order includes 4 species, viz. Vultur, Falco, Strix, Lanius. See these articles.

ORDER II. The PICÆ, have a convex, compressed BILL, resembling a knife.—This order contains 22 genera, viz. Buphaga, Certhia, Corvus, Cuculus, &c. See these articles.

ORDER III. The ANSERES, have an obtuse BILL, gibbous at the base, broadest at the point, covered with a smooth skin, and furnished with teeth: The tongue is fleshy; and the toes are palmated, or webbed.—This order includes 12 genera, viz. Alca, Anas, Colymbus, Diomedea, &c. See these articles.

ORDER IV. The GRALLÆ, have a long, obtuse, and somewhat cylindrical BILL: The tongue is undivided, and fleshy; and the thighs are naked. This order contains 18 genera, viz. Ardea, Falcia, Tringa, Charadrius, &c. See these articles.

ORDER V. The GALLINÆ, have a convex BILL; the superior mandible is vaulted over the inferior, and the margin of the superior mandible folds over the inferior one: The nostrils are half covered with a convex cartilaginous membrane: The rectrices, or principal quill-feathers of the tail, are always more than twelve in number; and the feet are divided, but connected at the innominate joint. —This order contains 7 genera, viz. Didus, Phasianus, Meleagris, Pavo, &c. See these articles.

ORDER VI. The PASSERES, have a conical sharp-pointed BILL; and the nostrils are oval, wide, and naked.—This order contains 15 genera, viz. Caprimulgus, Alauda, Columba, &c. See these articles.

The generic characters of this class are taken from peculiarities in the bill, the nostrils, the tongue, the feet, the feathers, the face, the figure of the body, &c.

The characters which serve to distinguish the species

are very various: For example, the colour of particular feathers or parts of feathers; crests of feathers on the head, disposed in different manners; the colour of the cere or wax; the colour of the feet; the shape and length of the tail; the number, situation, &c. of the toes; the colour and figure of the bill; &c.

The Third Class, AMPHIBIA, is divided into four ORDERS.

ORDER I. The REPTILES, have legs, and breathe by the mouth.—This order contains 4 genera, viz. Testudo, Draco, Lacerta, Rana. See these articles.

ORDER II. The SERPENTES, have no legs, and breathe by the mouth.—This order contains 6 genera, viz. Crotalus, Boa, Coluber, Anguis, Amphisbæna, Cœcilia. See these articles.

ORDER III. The NANTES, are furnished with lungs, and at the same time breathe by lateral gills; and the rays of their fins are cartilaginous. —This order contains 14 genera, viz. Accipenser, Balistes, &c. See these articles.

ORDER IV. The MEANTES, have both lungs and gills; and the feet are furnished with toes and claws.—This order contains but one genus, viz. the Siren. See SIREN.

The generic characters of this class are taken from the general figure of the body; from their having tails or no tails; being covered with a shell; having teeth or no teeth in the mouth; being furnished with wings; having covered or naked bodies; from the number, situation, and figure of the scuta and scales; from the number and situation of the spiracula; from the situation of the mouth, &c.

The specific characters are so very various, that it would be superfluous to enumerate them.

The Fourth Class, PISCES, is subdivided into four ORDERS, the characters of which are taken from the situation of the belly-fins.

ORDER I. The APODES, have no belly-fins.—This order contains 8 genera, viz. Animodytes, Anarrhicas, Muræna, &c. See these articles.

ORDER II. The JUGULARES, have the belly-fins placed before the pectoral fins.—This order includes 5 genera, viz. Callionymus, Bleennius, Gadus, &c. See these articles.

ORDER III. The THORACICI, have the belly-fins placed under the pectoral fins.—This order comprehends 17 genera, viz. Gubius, Labrus, Sparus, &c. See these articles.

ORDER IV. The ABDOMINALES, have the belly-fins placed behind the pectoral fins. This order contains 17 genera, viz. Fistularia, Esox, Clupea, Cyprinus, &c. See these articles.

The generic characters of this class are taken from peculiarities in the head, the mouth, the teeth, the nostrils, the rays in the membrane of the gills, the eyes, the general figure of the body, the figure of the tail, the situation of the spiracula, &c.

The specific characters are taken from peculiarities in all the parts above enumerated, and many others.

The *Fifth Class*, INSECTA, is subdivided into 7 ORDERS, the characters of which are taken from the wings.

ORDER I. The COLEOPTERA, have *four wings*, the two superior ones being crustaceous, and furnished with a *straight suture*.—This order comprehends 40 genera, viz. *Atelabus*, *Scarabeus*, *Coccinella*, *Melæ*, &c. See these articles.

ORDER II. The HEMIPTERA, have *four wings*, the two superior ones being *semicrustaceous*, and *incumbent*, i. e. the *interior edges* lie above one another.—This order includes 12 genera, viz. *Blatta*, *Gryllus*, *Cicada*, &c. See these articles.

ORDER III. The LEPIDOPTERA, have *four wings*, all of them imbricated with *scales*.—This order contains 3 genera, viz. *Papilio*, *Sphinx*, *Phalæna*. See these articles.

ORDER IV. The NEUROPTERA, have *four wings* interwoven with veins, like a piece of *network*, and *no sining* in the *anus*.—This order includes 7 genera, viz. *Libella*, *Ephemera*, *Hemerobius*, &c. See these articles.

ORDER V. The HYMENOPTERA, have the same characters with the former, only the *anus* is armed with a *sing*. But this mark is peculiar to the *females* and *neuters*; for the *males* have *no sing*.—This order comprehends 10 genera, viz. *Apis*, *Formica*, *Vespa*, &c. See these articles.

ORDER VI. The DIPTERA have *two wings*, and *two clavated balteres* or *balances* behind each wing.—This order contains 10 genera, viz. *Combylus*, *Afilus*, *Tipala*, &c. See these articles.

ORDER VII. The APTERA, have *no wings*. This order contains 14 species, viz. *Acarus*, *Aranea*, *Pediculus*, &c. See these articles.

N A T

NATURAL PHILOSOPHY, that which considers the powers and properties of natural bodies, and their mutual actions on one another. See MECHANICS, OPTICS, ASTRONOMY, HYDROSTATICS, PNEUMATICS.

NATURALIZATION. See LAW, Tit. x, 6.

NATURALS, among physicians, whatever naturally belongs to an animal, in opposition to non-naturals. See NON-NATURALS.

NATURE, according to Mr. Boyle, has eight different significations; it being used, 1. For the Author of nature, whom the schoolmen call *Natura Naturans*, being the same with God. 2. By the nature of a thing, we sometimes mean its essence; that is, the attributes which make it what it is, whether the thing be corporeal or not; as when we attempt to define the nature of a fluid, of a triangle, &c. 3. Sometimes we confound that which a man has by nature, with what accrues to him by birth; as when we say, that such a man is noble by nature. 4. Sometimes we take nature for an internal principle of motion; as when we say, that a stone by nature falls to the earth. 5. Sometimes we understand, by nature, the established course of things. 6. Sometimes we take nature for an aggregate of pow-

The *Sixth Class*, VERMES, is divided into five ORDERS.

ORDER I. The INTESTINA, are the most *simple animals*, being perfectly *naked*, and without *limbs* of any kind.—This order contains 7 genera, viz. *Lumbricus*, *Spinuaculus*, *Fasciola*, *Gordius*, *Alcasis*, *Hirudo*, *Mycine*. See these articles.

ORDER II. The MOLLUSCA, are likewise *simple naked animals*, without any *shell*; but they are *brachiated*, or furnished with a kind of *limb*.—This order comprehends 18 genera, viz. *Ascidia*, *Limare*, *Doris*, *Tethys*, *Aphrodita*, *Sepia*, &c. See these articles.

ORDER III. The TESTACEA, have the same characters with those of Order II. but are covered with a *shell*.—This order includes 39 genera, viz. *Anomia*, *Cardium*, *Argonauta*, *Bulla*, *Buccinum*, &c.

ORDER IV. The LITHOPHYTA, are *compound animals*, fixed upon a *calcareous base* constructed by the creatures *themselves*.—This order includes the corals, of which there are 4 genera, viz. *Tubipora*, *Madrepora*, &c. See these articles.

ORDER V. The ZOOPHYTA, are *compound animals*, furnished with a kind of *flowers*, and having a *vegetating root* and *stem*.—This order contains 15 genera, viz. *Spongia*, *Gorgonia*, *Tubularia*, *Hydra*, &c. See these articles.

This short explanation will enable any person who understands the Latin language to peruse the *Sytlema Naturæ* of Linnæus without the assistance of a master; which was the principal object of this article.

N A T

powers belonging to a body, especially a living one; in which sense physicians say, that nature is strong, weak, or spent; or that, in such or such diseases, nature left to herself will perform the cure. 7. Sometimes we use the term nature for the universe, or whole system of the corporeal works of God; as when it is said of a phoenix, or chimera, that there is no such thing in nature. 8. Sometimes too, and that most commonly, we express by the word nature a kind of semi-deity, or other strange kind of being.

If, says the same philosopher, I were to propose a notion of nature, less ambiguous than those already mentioned, and with regard to which many axioms relating to that word may be conveniently understood, I should first distinguish between the universal and the particular nature of things. Universal nature I would define to be the aggregate of the bodies that make up the world, in its present state, considered as a principle; by virtue whereof they act and suffer, according to the laws of motion prescribed by the Author of all things. And this makes way for the other subordinate notion; since the particular nature of an individual consists in the general nature applied to a distinct portion of the universal

universe; or, which is the same thing, it is a particular assemblage of the mechanical properties of matter, as figure, motion, &c.

NAVARINO, a port-town of European Turkey in the Morea, ninety-miles south-west of Corinth.

NAVARRÉ, a province of Spain, bounded by French Navarre on the north-east, by Arragon on the south-east, by Old Castile on the south-west, and by Guipuscoa on the west: it is a mountainous country.

French Navarre, separated from Spanish Navarre on the south-west by the Pyrenees: it is only thirty miles long, and fifteen broad; being one of the most barren provinces in France.

NAVE, in architecture, the body of a church where the

people are disposed, reaching from the balluster, or rail of the choir, to the chief door.

NAVEL, in anatomy, the centre of the lower part of the abdomen; being that part where the umbilical vessels passed out of the fetus to the placenta of the mother. See MIDWIFERY.

NAVEL-WORT, in botany. See COTYLEDON.

NAVEREINI, a town of Gascony, in France, sixteen miles south-east of Bayonne.

NAVEW, in botany. See BRASSICA, of which it is a species.

NAVICULARE os, in anatomy. See ANAT. p. 186.

NAVIDAD, a port-town of Mexico, in the province of Mechoachan: W. long. 110°, and N. lat. 19°.

NAVIGATION.

NAVIGATION, is the art of conducting or carrying a ship from one port to another. In order to understand this science, particularly the theoretical parts of it, it is necessary that the student be acquainted with the general principles of GEOMETRY, ASTRONOMY, and TRIGONOMETRY. See these articles.

SECT. I. Of the LOG-LINE and COMPASS.

1. THE method commonly made use of for measuring a ship's way at sea, or how far she runs in a given space of time, is by the log-line, and half-minute glass.

2. The log is a flat piece of wood, in shape like a flounder, having a piece of lead fastened to its bottom, which makes it stand or swim upright in the water: to this log is tied or fastened a long line, which is called the log-line; and this is commonly divided into certain spaces, each of which is, or ought to be, such a proportional part of a nautical mile (60 of which make a degree of a great circle on the earth) as half a minute (the time allowed for the experiment) is of an hour.

3. These spaces are called knots, because at the end of each of them there is a piece of twine with knots in it, interwoven between the strands of the line, which shews how many of these spaces or knots are run out during the half minute. They commonly begin to be counted at the distance of about 10 fathom or 60 feet from the log; that so the log, when it is hove over board, may be out of the eddy of the ship's wake before they begin to count; and for the more ready discovery of this point of commencement, there is commonly fastened at it a piece of red rag.

4 The log being thus prepared, and hove over board from the poop, and the line veered out (by the help of a reel, that turns easily, and about which it is wound) as fast as the log will carry it away, or rather as the ship sails from it, will shew, according to the time of veering, how far the ship has run in a given time, and consequently her rate of sailing.

5. A degree of a meridian, according to the exactest measures, contains about 69.545 English miles; and each mile by the statute being 5280 feet, therefore a degree

of a meridian will be about 367200 feet; whence the $\frac{1}{60}$ of that, viz. a minute, or nautical mile, must contain 6120 standard feet; consequently, since $\frac{1}{2}$ minute is the $\frac{1}{120}$ part of an hour, and each knot being the same part of a nautical mile, it follows, that each knot will contain the $\frac{1}{120}$ of 6120 feet, viz. 51 feet.

6. Hence it is evident, that whatever number of knots the ship runs in half a minute, the same number of miles she will run in one hour, supposing her to run with the same degree of velocity during that time; and therefore it is the general way to heave the log every hour to know her rate of sailing: but if the force or direction of the wind vary, and not continue the same during the whole hour; or if there has been more sail set, or any sail handed, that so the ship has run swifter or slower in any part of the hour than she did at the time of heaving the log; then there must be an allowance made accordingly for it, and this must be according to the discretion of the artist.

7. Sometimes when the ship is before the wind, and there is a great sea setting after her, it will bring home the log, and consequently the ship will sail faster than is given by the log. In this case it is usual, if there be a very great sea, to allow one mile in ten, and less in proportion, if the sea be not so great. But for the generality, the ship's way is really greater than that given by the log; and therefore, in order to have the reckoning rather before than behind the ship, (which is the safest way,) it will be proper to make the space on the log-line between knot and knot to consist of 50 feet instead of 51.

8 If the space between knot and knot on the log-line should happen to be too great in proportion to the half-minute glass, viz. greater than 50 feet, then the distance given by the log will be too short; and if that space be too small, then the distance run (given by the log) will be too great; therefore to find the true distance run in either case, having measured the distance between knot and knot, we have the following proportion, viz.

As the true distance, 50 feet, is to the measured distance; so are the miles of distance given by the log, to the true distance in miles that the ship has run.

EXAMPLE

EXAMPLE I. Suppose a ship runs at the rate of $6\frac{1}{2}$ knots in half a minute; but measuring the space between knot and knot, I find it to be 56 feet: Required the true distance in miles.

Making it, As 50 feet is to 56 feet, so is 6.25 knots to 7 knots; I find that the true rate of sailing is 7 miles in the hour.

EXAMPLE II. Suppose a ship runs at the rate of $6\frac{1}{2}$ knots in half a minute; but measuring the space between knot and knot, I find it to be only 44 feet: Required the true rate of sailing.

Making it, As 50 feet is to 44 feet, so is 6.5 knots to 5.72 knots; I find that the true rate or sailing is 5.72 miles in the hour.

9. Again, supposing the distance between knot and knot on the log line to be exactly 50 feet, but that the glass is not 30 seconds; then, if the glass require longer time to run than 30 seconds, the distance given will be too great, if estimated by allowing 1 mile for every knot run in the time the glass runs; and, on the contrary, if the glass requires less time to run them 30 seconds, it will give the distance failed too small. Consequently, to find the true distance in either case, we must measure the time the glass requires to run out (by the method in the following article;) then we have the following proportion, *viz.*

As the number of seconds the glass runs, is to half a minute, or 30 seconds; so is the distance given by the log, to the true distance.

EXAMPLE I. Suppose a ship runs at the rate of $7\frac{1}{2}$ knots in the time the glass runs; but measuring the glass, I find it runs 34 seconds: Required the true distance failed.

Making it, As 34 seconds is to 30 seconds, so is 7.5 to 6.6; I find that the ship sails at the rate of 6.6 miles an hour.

EXAMPLE II. Suppose a ship runs at the rate of $6\frac{1}{2}$ knots; but measuring the glass, I find it runs only 25 seconds: Required the true rate of sailing.

Making it, As 25 seconds is to 30 seconds, so is 6.5 knots to 7.8 knots; I find that the true rate of sailing is 7.8 miles an hour.

10. In order to know how many seconds the glass runs, you may try it by a watch or clock, that vibrates seconds; but if neither of these be at hand, then take a line, and to the one end fastening a plummet, hang the other upon a nail or peg, so as the distance from the peg to the centre of the plummet be 39 $\frac{1}{2}$ inches: Then this put into motion will vibrate seconds; *i. e.* every time it passes the perpendicular, you are to count one second; consequently, by observing the number of vibrations that it makes during the time the glass is running, we know how many seconds the glass runs.

11. If there be an error both in the log line and half-minute glass, *viz.* if the distance between knot and knot and the log-line be either greater or less than 50 feet, and the glass runs either more or less than 30 seconds; then the finding out the ship's true distance will be somewhat more complicate, and admit of three cases, *viz.*

CASE I. If the glass runs more than 30 seconds, and the distance between knot and knot be less than 50 feet, then the distance given by the log line, *viz.* by allowing

1 mile for each knot the ship sails while the glass is running, will always be greater than the true distance, since either of these errors give the distance too great. Consequently, to find the true rate of sailing in this case, we must first find (by Art. 8.) the distance, on the supposition that the log-line is only wrong, and then with this (by Art. 9.) we shall find the true distance.

EXAMPLE. Suppose a ship is found to run at the rate of 6 knots; but examining the glass, I find it runs 35 seconds; and measuring the log-line, I find the distance between knot and knot to be but 46 feet: Required the true distance run.

First, (by Art. 8.) We have the following proportion, *viz.* As 50 feet : 46 feet :: 6 knots : 5.52 knots. Then (by Art. 9.) As 35 seconds : 30 seconds :: 5.52 knots : 4.73 knots. Consequently the true rate of sailing is 4.73 miles an hour.

CASE II. If the glass be less than 30 seconds, and the place between knot and knot be more than 50 feet; then the distance given by the log will always be less than the true distance, since either of these errors lessen the true distance.

EXAMPLE. Suppose a ship is found to run at the rate of 7 knots; but examining the glass, I find it runs only 25 seconds; and measuring the space between knot and knot on the log line, I find it is 54 feet: Required the true rate of sailing.

First, (by Art. 9.) As 25 seconds : 30 seconds :: 7 knots : 8.4 knots. Then (by Art. 8.) As 50 feet : 54 feet :: 8.4 knots : 9.072 knots. Consequently the true rate of sailing is 9.072 miles an hour.

CASE III. If the glass runs more than 30 seconds, and the space between knot and knot be greater than 50 feet; or if the glass runs less than 30 seconds, and the space between knot and knot be less than 50 feet: then, since in either of these two cases the effects of the errors are contrary, it is plain the distance will sometimes be too great, and sometimes too little, according as the greater quantity of the error lies; as will be evident from the following examples.

EXAMPLE I. Suppose a ship is found to run at the rate of $9\frac{1}{2}$ knots per glass; but examining the glass, it is found to run 36 seconds; and by measuring the space between knot and knot, it is found to be 58 feet: Required the true rate of sailing.

First, (by Art. 8.) As 50 feet : 58 feet :: 9.5 knots : 11.02 knots. Then (by Art. 9.) As 38 seconds : 30 seconds :: 11.02 knots : 8.7 knots. Consequently the ship's true rate of sailing is 8.7 miles an hour.

EXAMPLE II. Suppose a ship runs at the rate of 6 knots per glass; but examining the glass, it is found to run only 20 seconds; and by measuring the log-line, the distance between knot and knot is found to be but 38 feet: Required the true rate of sailing.

First, (by Art. 8.) As 50 feet : 38 feet :: 6 knots : 4.56 knots. Then (by Art. 9.) As 20 seconds : 30 seconds :: 4.56 knots : 6.84 knots. Consequently the true rate of sailing is 6.83 miles an hour.

But if in this case it happen, that the time the glass takes to run be to the distance between knot and knot, as 30, the seconds in half a minute, is to 50, the true distance

distance between knot and knot; then it is plain, that whatever number of seconds the glass consists of, and whatever number of feet is contained between knot and knot; yet the distance given by the log line, will be the true distance in miles.

12. Though the method of measuring the ship's way by the log-line, described in the foregoing articles, be that which is now commonly made use of; yet it is subject to several errors, and these very considerable. For first, the half minute or quarter-minute glasses (by which, and the log, the ship's way is determined) are seldom or never true, because dry and wet weather have a great influence on them; so that at one time they may run more, and at another time fewer than 30 seconds, and it is evident that a small error in the glass will cause a sensible one in the ship's way. Again, the chief property of the log is to have it swim upright, or perpendicular to the horizon: but this too often wanting in logs, because few seamen examine whether it is so or not, and generally take it upon trust, being satisfied if it weigh a little more at the stern than the head: and from this there flows an error in the reckoning; for if the log does not swim upright, it will not hold water, nor remain steady in the place where it is heaved, since the least check in the hand in veering the line will make it come up several feet: this repeated will make the errors become fathoms, and perhaps knots, which, how insignificant soever they appear, are miles and parts of miles, and amount to a good deal in a long voyage. Another inconvenience attending the log line is its stretching and shrinking; for when a new line is first used, let it be ever so well stretched upon the deck, and measured as true as possible, yet after wetting it shrinks considerably; and consequently to be the better assured of the ship's way by the log-line, we ought to measure and alter the knots on it every time before we use it; but this is seldom done oftner than once a week, and sometimes not above once or twice in a whole voyage; also when the line is measured to its greatest degree of shrinking, it is generally left there; and when, by much use, it comes to stretch again, it is seldom or never mended, though it will stretch beyond what it first shrunk. These, and many other errors, too well known, attending that method of measuring the ship's way by the log-line, plainly answers for a great many errors committed in reckonings. So it is to be wished, that either this method were improved or amended, or that some other method less subject to error were found out.

13. The meridian and prime vertical of any place cuts the horizon in 4 points, at 90 degrees distance from one another, viz. *North, South, East, and West*; that part of the meridian which extends itself from the place to the north point of the horizon is called the *north line*; that which tends to the south point of the horizon, is called the *south line*; and that part of the prime vertical which extends towards the right hand of the observer, when his face is turned to the north, is called the *east line*; and lastly, that part of the prime vertical which tends towards the left hand, is called the *west line*; the four points in which these lines meet the horizon, are called the *cardinal points*.

VOL. III. N^o. 84.

2

14. In order to determine the course of the winds, and to discover their various alterations or shifts; each quadrant of the horizon intercepted between the meridian and prime vertical, is usually divided into eight equal parts, and consequently the whole horizon into thirty-two; and the lines drawn from the place on which the observer standeth, to the points of division in his horizon, are called *rum lines*, the four principal of which are those described in the preceding article, each of them having its name from the cardinal point in the horizon towards which it tends; the rest of the rum lines have their names compounded of the principal lines on each side of them, as in the figure; (*see Navigation Plater*, No. 1.) and over which-soever of these lines the course of the wind is directed, that wind takes its name accordingly.

15. The instrument commonly used at sea for directing the ship's way, is called the mariner's compass; which consists of a card and two boxes. The card is a circle made to represent the horizon, whose circumference is quartered and divided into degrees, and also into thirty-two equal parts, by lines drawn from the centre to the several points of division, called points of the compass. On the back side of the card, and just below the south and north line, is fixed a steel needle with a brass cupola, or hollow center in the middle, which is placed upon the end of a fine pin, upon which the card may easily turn about; the needle is touched with a load stone, by which a certain virtue is infused into it, that makes it (and consequently the south and north line on the card above it) hang nearly in the plane of the meridian, by which means the south and north lines on the card produced would meet the horizon in the south and north points; and consequently all the other lines on the card produced would meet the horizon in the respective points.

16. The card is represented in No. 1, in which you may observe, that the capital letters N, S, E, W, denote the four cardinal points, viz. N the *North*, S the *South*, &c. and the small letter *b* signifies the word *by*: the *Rhomb* in the middle between any two of the cardinals are expressed by the letters denoting these cardinals, that which denotes the point lying in the meridian having the precedence; thus the rhomb in the middle between the north and east is expressed N E, which is to be read *North-East*; also S W denotes the *South-West* rhomb, &c. the other rhombs are expressed according to their situation with respect to these middle rhombs, and the nearest cardinals, as is plain from the foregoing figure.

17. The card is put into a round box, made for it, having a pin erected in the middle, upon which the hollow centre of the needle is fixed, so as the card may lie horizontal, and easily vibrate according to the motion of the needle: the box is covered over with a smooth glass, and is hung in a brass hoop upon two cylindrical pins, diametrically opposite to one another; and this hoop is hung within another brass circle, upon two pins at right angles with the former. These two circles, and the box, are placed in another square wooden box, so that the innermost box, and consequently the card, may keep horizontal which way soever the ship heels.

18. Since the meridians do all meet at the poles, and

4 Z

†

there

there form certain angles with one another; and since, if we move never so little towards the east or west, from one place to another, we thereby change our meridian, and in every place the east and west line being perpendicular to the meridian; it follows, that the east and west line in the first place will not coincide with the east and west line in the second, but be inclined to it at a certain angle: and consequently all the other rhomb lines at each place will be inclined to each other, they always forming the same angles with the meridian. Hence it follows, that all rhombs, except the four cardinals, must be curves or helispherical lines, always tending towards the pole, and approaching it by infinite gyrations or turnings, but never falling into it. Thus let P (No. 2.) be the pole, EQ an arch of the equator, PE PA, &c. meridians, and EFGHKL any

rhomb: then because the angles PEF, PFG, &c. are by the nature of the rhomb line equal, it is evident that it will form a curve line on the surface of the globe, always approaching the pole P, but never falling into it; for if it were possible for it to fall into the pole, then it would follow, that the same line could cut an infinite number of other lines at equal angles, in the same point; which is absurd.

19. Because there are 32 rhumbs (or points in the compass) equally distant from one another, therefore the angle contained between any two of them adjacent will be $11^{\circ} 15'$, viz. $\frac{1}{16}$ part of 360° ; and so the angle contained between the meridian and the NNE, will be $11^{\circ} 15'$, and between the meridian and the NNE will be $22^{\circ} 30'$; and so of the rest, as in the following table.

A Table of the Angles which every $\frac{1}{16}$ Point of the Compass makes with the Meridian.

SECT. 2. OF PLAIN SAILING.

1. THIS method of sailing supposes the earth to be a plane, and the meridians parallel to one another; and likewise the parallels of latitude at equal distance from one another, as they really are upon the globe. Though this method be in itself evidently false; yet in a short run, and especially near the equator, an account of the ship's way may be kept by it tolerably well.

2. The angle formed by the meridian and rhumb that a ship sails upon, is called the ship's course. Thus if a ship sails on the NNE rhomb, then her course will be $22^{\circ} 30'$, and so of others.

3. The distance between two places lying on the same parallel counted in miles of the equator, or the distance of one place from the meridian of another counted as above on the parallel passing over that place, is called meridional distance; which, in plain sailing, goes under the name of departure.

4. Let A ($N^{\circ} 3.$) denote a certain point on the earth's surface, AC it's meridian, and AD the parallel of lati-

tude passing through it; and suppose a ship to sail from A on the NNE rhomb till she arrive at B; and through B draw the meridian BD, (which, according to the principles of plain sailing, must be parallel to CA,) and the parallel of latitude BC; then the length of AB, viz. how far the ship has sailed upon the NNE rhomb, is called her distance; AC or BD will be her difference of latitude, or northing; CB will be her departure, or easting; and the angle CAB will be the course. Hence it is plain, that the distance sailed will always be greater than either the difference of latitude or departure; it being the hypotenuse of a right angled triangle, whereof the other two are the legs; except the ship sails either on a meridian, or a parallel of latitude; for if the ship sails on a meridian, then it is plain, that her distance will be just equal to her difference of latitude, and she will have no departure; but if she sail on a parallel, then her distance will be the same with her departure, and she will have no difference of latitude. It is evident also from the figure, that if the course be less than 4 points, or 45 degrees, its complement, viz. the other oblique angle, will be greater

greater than 45 degrees, and so the difference of latitude will be greater than the departure; but if the course be greater than 4 points, then the difference of latitude will be less than the departure; and lastly, if the course be just 4 points, the difference of latitude will be equal to the departure.

5. Since the distance, difference of latitude, and departure, form a right-angled triangle, in which the oblique angle opposite to the departure is the course, and the other its complement; therefore, having any two of these given, we can (by plain trigonometry) find the rest; and hence arise the cases of plain-sailing, which are as follow.

CASE I. Course and distance given, to find difference of latitude and departure.

EXAMPLE. Suppose a ship sails from the latitude of $30^{\circ} 25'$ north, NNE, 32 miles, (No. 4.) Required the difference of latitude and departure, and the latitude come to. Then (by right angle trigonometry,) we have the following analogy, for finding the departure, viz.

As radius	—	—	—	10.00000
to the distance AC	—	32	—	1.50515
so is the sine of the course A $22^{\circ} 30'$	—	—	—	9.58284
to the departure BC	—	12.25	—	1.08799

so the ship has made 12.25 miles of departure easterly, or has got so far to the eastward of her meridian. Then for the difference of latitude or northing the ship has made, we have (by rectangular trigonometry) the following analogy, viz.

As radius	—	—	—	10.00000
is to the distance AC	—	32	—	1.50515
so is the cosine of course A	—	$22^{\circ} 30'$	—	9.96562
to the difference of lat. AB	—	29.57	—	1.47077

so the ship has differed her latitude, or made of northing, 29.57 minutes.

And since her former latitude was north, and her difference of latitude also north; therefore,

To the latitude failed from	—	—	$30^{\circ} 25' N$
add the difference of latitude	—	—	$00^{\circ} 29' 57''$

and the sum is the latitude come to $30^{\circ} 54' 57'' N$

By this case are calculated the tables of difference of latitude, and departure, to every degree, point, and quarter-point of the compass.

CASE II. Course and difference of latitude given, to find distance and departure.

EXAMPLE. Suppose a ship, in the latitude of $45^{\circ} 25'$ north, sails NE $\frac{1}{2}$ easterly (No 5.) till she come to the latitude of $46^{\circ} 55'$ north. Required the distance and departure made good upon that course.

Since both latitudes are northerly, and the course also northerly; therefore,

From the latitude come to	—	—	$46^{\circ} 55'$
subtract the latitude failed from	—	—	$45^{\circ} 25'$
and their remains	—	—	$01^{\circ} 30'$

the difference of latitude, equal to 90 miles.

And (by rectangular trigonometry) we have the following analogy, for finding the departure BD, viz.

As radius	—	—	—	10.00000
is to the diff. of latitude AB	—	90	—	1.95424

so is the tangent of course A — $39^{\circ} 22'$ 9.91404
to the departure BD — — — 73 84 1.86828
so the ship has got 73 84 miles to the eastward of her former meridian.

Again, for the distance AD, we have (by rectangular trigonometry) the following proportion, viz.

As radius	—	—	—	10.00000
is to the secant of the course	—	$39^{\circ} 22'$	—	10.11176
so is the difference of latitude AB 90	—	—	—	1.95424
to the distance AD	—	—	—	116.4 2.06600

CASE III. Difference of latitude and distance given, to find course and departure.

EXAMPLE. Suppose a ship sails from the latitude of $56^{\circ} 50'$ north, on a rhomb between south and west, 126 miles, and she is then found by observation to be in the latitude of $55^{\circ} 40'$ north. Required the course she failed on, and her departure from the meridian. No 6.

Since the latitudes are both north, and the ship sailing towards the equator; therefore,

From the latitude failed from	—	—	$56^{\circ} 50'$
subtract the observed latitude	—	—	$55^{\circ} 10'$

and the remainder — — — $01^{\circ} 40'$
equal to 70 miles, is the difference of latitude.

By rectangular trigonometry we have the following proportion for finding the angle of the course F, viz.

As the distance failed DF	—	126	—	2.10037
is to radius	—	—	—	10.00000
so is the diff. of latitude FD	—	70	—	1.84510
to the co-sine of the course F	—	$56^{\circ} 15'$	—	9.74473

which, because she fails between south and west, will be south $56^{\circ} 15'$ west, or SW $\frac{1}{2}$ W. Then, for the departure, we have (by rectangular trigonometry) the following proportion, viz.

As radius	—	—	—	10.00000
is to the distance failed DF	—	126	—	2.10037
so is the sine of the course F	—	$56^{\circ} 15'$	—	9.91985
to the departure DE	—	—	—	104 8 — 2.02022

consequently she has made 104.8 miles of departure westerly.

CASE IV. Difference of latitude and departure given, to find course and distance.

EXAMPLE. Suppose a ship sails from the latitude of $44^{\circ} 50'$ north, between south and east, till she has made 64 miles of easting, and is then found by observation to be in the latitude of $42^{\circ} 56'$ north. Required the course and distance made good.

Since the latitudes are both north, and the ship sailing towards the equator; therefore,

From the latitude failed from	—	—	$44^{\circ} 50' N$
take the latitude come to	—	—	$42^{\circ} 56'$

and their remains — — — $01^{\circ} 54'$
equal to 114 miles, the difference of latitude or southing.

In this case by (rectangular trigonometry) we have the following proportion to find the course KGL (No. 7.) viz.

As the diff. of latitude GK	114	—	2.05690
is to radius	—	—	10.00000
so is the departure KL	—	64	1.80618

to

to the trangent of course G — $29^{\circ} 19'$ — 9.74928
which, because the ship is failing between south and east,
will be fourth $29^{\circ} 19'$ east, or SSE $\frac{1}{2}$ east nearly.

Then for the distance, we shall have (by rectangular trigonometry) the following analogy, viz.

As radius	—	—	10.00000
is to the diff. of latitude GK	114	—	2.05690
so is the secant of the course	$29^{\circ} 19'$	—	10.05952
to the distance GL	—	130.8	— 2.11642

consequently the ship has sailed on a SSE $\frac{1}{2}$ east course
130.8 miles.

CASE V. Distance and departure given, to find course and difference of latitude.

EXAMPLE. Suppose a ship at sea fails from the latitude of 34° north, between north and west 124 miles, and is found to have made of westing 86 miles. Required the course steered, and the difference of latitude or northing made good.

In this case (by rectangular trigonometry) we have the following proportion for finding the course ADB, (No. 8.) viz.

As the distance AD	—	124	—	2.09342
is to radius	—	—	—	10.00000
so is the departure AB	—	86	—	1.93450
to the sine of the course D	$43^{\circ} 54'$	—	—	9.84108

so the ship's course is north $33^{\circ} 54'$ west, or NWbN $\frac{1}{4}$ west nearly.

Then for the difference of latitude, we have (by rectangular trigonometry) the following analogy, viz.;

As radius	—	—	10.00000
is to the distance AD	—	124	— 2.09342
so is the cosine of the course $43^{\circ} 54'$	—	—	9.85766
to the diff. of latitude BD	—	89.35	— 1.95108

which is equal to 1 degree and 29 minutes nearly. Hence, to find the latitude the ship is in, since both latitudes are north, and the ship failing from the equator; therefore,

To the latitude sailed from	—	—	$34^{\circ} 24'$
add the difference of latitude	—	—	$1^{\circ} 29'$

the sum is	—	—	$35^{\circ} 53'$
------------	---	---	------------------

the latitude the ship is in north.

CASE VI. Course and departure given, to find distance and difference of latitude.

EXAMPLE. Suppose a ship at sea, in the latitude of $24^{\circ} 30'$ south, fails SEbS, till she has made of easting 96 miles. Required the distance and difference of latitude made good on that course.

In this case, by Rectangular Trigonometry, and by Case 2. we have the following proportion for finding the distance, (No 9.) viz.

As the sine of the course G	$33^{\circ} 45'$	—	9.74474
is to the departure HM	—	96	— 1.98227
so is radius	—	—	10.00000
to the distance GM	—	172.8	— 2.23753

Then, for the difference of latitude, we have (by rectangular trigonometry) the following analogy, viz.

As the tangent of course	—	$33^{\circ} 45'$	— 9.82489
is to the departure HM	—	96	— 1.98227
so is radius	—	—	10.00000
to the difference of latitude GH	—	143.7	— 2.15738

equal to $2^{\circ} 24'$ nearly. Consequently, since the latitude the ship sailed from was south, and the sailing still towards the south,

To the latitude sailed from	—	—	$24^{\circ} 30'$
add the difference of latitude	—	—	$2^{\circ} 24'$

and the sum	—	—	$26^{\circ} 54'$
-------------	---	---	------------------

is the latitude she is come to south.

6. When a ship stems several courses in 24 hours, then the reducing all these into one, and thereby finding the course and distance made good upon the whole, is commonly called the resolving of a traverse.

7. At sea they commonly begin each day's reckoning from the noon of that day, and from that time they set down all the different courses and distances stemmed by the ship till noon next day upon the log-board; then from these several courses and distances had from the compass and log line, they compute the difference of latitude and departure for each course (by Case 1. of Plain Sailing;) and these, together with the courses and distances, are set down in a table called the traverse table, which consists of five columns: in the first of which are placed the courses and distances; in the two next the differences of latitude belonging to these courses, according as they are north or south; and in the two last are placed the departures belonging to these courses, according as they are east or west. Then they sum up all the northings, and all the southings; and taking the difference of these, they know the difference of latitude made good by the ship in the last 24 hours, which will be north or south, according as the sum of the northings or southings is greatest: The same way, by taking the sum of all the eastings, and likewise of all the westings, and subtracting the lesser of these from the greater, the difference will be the departure made good by the ship last 24 hours, which will be east or west according as the sum of the eastings is greater or less than the sum of the westings; then from the difference of latitude and departure made good by the ship last 24 hours, found as above, they find the true course and distance made good upon the whole (by Case 4. of Plain Sailing), as also the course and distance to the intended port.

EXAMPLE. Suppose a ship at sea, in the latitude of $48^{\circ} 24'$ north at noon any day, is bound to a port in the latitude of $43^{\circ} 40'$ north, whose departure from the ship is 144 miles east; consequently the direct course and distance of the ship is SSE $\frac{1}{2}$ east 315 miles; but by reason of the shifting of the winds she is obliged to steer the following courses till noon next day, viz. SEbS 56 miles, SSE 64 miles, NWbW 48 miles, SbW $\frac{1}{2}$ west 54 miles, and SEbS $\frac{1}{2}$ east 74 miles. Required the course and distance made good the last 24 hours, and the bearing and distance of the ship from the intended port.

The solution of this traverse depends entirely on the 1st and 4th cases of Plain Sailing; and first we must (by Case 1.) find the difference of latitude and departure for each course. Thus,

1 Course SEbS distance 56 miles.
For departure.

As radius	—	—	10.00000
is to the distance	—	56	— 1.74819

10

So is the sine of the course 33°, 45' — 9.74474
to the departure — 31.11 — 1.49293

For difference of latitude.

As radius — — — 10.00000
is to the distance — 56 — 1.74819
so is the co-sine of the course 33°, 45' — 9.91985
to the diff. of latitude — 46.57 — 1.66804

2. Course SSE and distance 64 miles.

For departure.

As radius — — — 10.00000
is to the distance — 64 — 1.80618
so is the sine of the course 22°, 30' — 9.58284
to the departure — 22.5 — 1.38902

For difference of latitude.

As radius — — — 10.00000
is to the distance — 64 — 1.80618
so is the co-sine of the course 22°, 30' — 9.96562
to the difference of latitude 59.13 — 1.77180

3. Course NW½W and distance 48 miles.

For departure.

As radius — — — 10.00000
is to the distance — 48 — 1.68124
so is the sine of the course 56°, 15' — 9.91985
to the departure — 39.91 — 1.60109

For difference of latitude.

As radius — — — 10.00000
is to the distance — 48 — 1.68124
so is the co-sine of the course 56°, 15' — 9.74474
to the difference of latitude 26.67 — 1.42598

4. Course S½W ½ west and distance 54 miles.

For departure.

As radius — — — 10.00000
is to the distance — 54 — 1.73239
so is the sine of the course 16°, 52' — 9.46262
to the departure — 15.67 — 8.19501

For difference of latitude.

As radius — — — 10.00000
is to the distance — 54 — 1.73239
so is the co-sine of the course 16°, 52' — 9.98090
to the difference of latitude 51.67 — 1.71329

5. Course SE½S ½ east and distance 74 miles.

For departure.

As radius — — — 10.00000
is to the distance — 74 — 1.86923
so is the sine of the course 39°, 22' — 9.80228
to the departure — 46.94 — 1.67151

For difference of latitude.

As radius — — — 10.00000
is to the distance — 74 — 1.86923
so is the co-sine of the course 39°, 22' — 9.88824
to the difference of latitude 57.21 — 1.75747

Now these several courses and distances, together with the differences of latitude and departures deduced from them, being set down in their proper columns in the traverse table, will stand as on next column.

From that table it is plain, since the sum of the northings is 26.67, and of the southings 214.58, the difference between these, viz. 187.91, will be the southing made good by the ship the last 24 hours; also the sum of the eastings being 102.55, and of the westings 55.58, the difference 46.97 will be the easting or departure made good by the ship's

The TRAVERSE TABLE.

Courses	Distances	Diff. of Lat.		Departure	
		N	S	E	W
SE ½ S —	56 —		46.57	31.11	
SSE —	64 —		59.13	24.5	
NW ½ W —	48 26.67.				39.91
S ½ W ½ West —	54 —		51.67		15.67
SE ½ S ½ East —	94 —		57.21	46.94	
		26.67	214.58	102.55	55.58
			26.67	55.58	

Diff. of Lat. 187.91 46.97 Dep.

last 24 hours; consequently, to find the true course and distance made good by the ship in that time, it will be, (by Case 4. of Plain Sailing.)

As the difference of latitude — 187.91 2.27393
is to radius — — — 10.00000

so is the departure — — — 46.97 1.67182
to the tangent of the course 14°. 03' — 9.39789

which is S½E ½ east nearly. Then for the distance, it will be,
As radius — — — 10.00000

is to the difference of latitude 187.91 2.27393
so is the secant of the course 14°, 03' 10.01319

to the distance — — — 193.7 2.28712

consequently the ship has made good the last 24 hours, on a S½E ½ east course, 193.7 miles: And since the ship is failing towards the equator; therefore,

From the latitude sailed from — — — 48°, 24' N
take the diff. of latitude made good — — — 3, 08 S

there remains — — — 45, 16 N

the latitude the ship is in north. And because the port the ship is bound for lies in the latitude of 43° 40' north, and consequently south of the ship; therefore,

From the latitude the ship is in — — — 45°, 16' N
take the latitude she is bound for — — — 43, 40 N

and there remains — — — 1, 36

or 96 miles, the difference of latitude or southing the ship has to make. Again, the whole easting the ship had to make being 144 miles, and she having already made

46.97 or 47 miles of easting; therefore the departure or easting the ship has to make will be 97 miles; consequently,

to find the direct course and distance between the ship and the intended port, it will be (by Case 4. of Plain Sailing)

As the difference of latitude — 96 — 1.98227
is to radius — — — 10.00000

so is the departure — — — 97 — 1.98677
to the tangent of the course — — — 45°, 19' 10.00450

And

As radius — — — 10.00000
is to the difference of latitude 96 — 1.98227

so is the secant of the course 45°, 19' — 10.15293
to the distance — — — 136.5 — 2.13620

whence the true bearing and distance of the intended port is SE, 136.5 miles.

† 5 A

S &.

SECT. 3. OF PARALLEL SAILING.

1. SINCE the parallels of latitude do always decrease the nearer they approach the pole, it is plain a degree on any of them must be less than a degree upon the equator. Now in order to know the length of a degree on any of them, let PB (No. 10.) represent half the earth's axis; PA a quadrant of a meridian, and consequently A a point on the equator, C a point on the meridian, and CD a perpendicular from that point upon the axis, which plainly will be the sine of CP the distance of that point from the pole, or the co-sine of CA its distance from the equator; and CD will be to AB, as the sine of CP, or co-sine of CA, is to the radius. Again, if the quadrant PAB is turned round upon the axis PB, it is plain the point A will describe the circumference of the equator whose radius is AB, and any other point C upon the meridian will describe the circumference of a parallel whose radius is CD.

COR. I. Hence (because the circumference of circles are as their radii) it follows, that the circumference of any parallel is to the circumference of the equator, as the co-sine of its latitude is to radius.

COR. II. And since the wholes are as their similar parts, it will be, As the length of a degree on any parallel is to the length of a degree upon the equator, so is the co-sine of the latitude of that parallel to radius.

COR. III. Hence, as radius is to the co-sine of any latitude, so are the minutes of difference of longitude between two meridians, or their distance in miles upon the equator, to the distance of these two meridians on the parallel in miles.

COR. IV. And as the co-sine of any parallel is to radius, so is the length of any arch on that parallel (intercepted between two meridians) in miles, to the length of a similar arch on the equator, or minutes of difference of longitude.

COR. V. Also, as the co-sine of any one parallel is to the co-sine of any other parallel, so is the length of any arch on

the first, in miles, to the length of the same arch on the other in miles.

2. From what has been said, arises the solution of the several cases of parallel sailing, which are as follow.

CASE I. Given the difference of longitude between two places, both lying on the same parallel; to find the distance between those places.

EXAMPLE I. Suppose a ship in the latitude of $54^{\circ} 20'$ north, sails directly west on that parallel till she has differed her longitude $12^{\circ} 45'$; required the distance sailed on that parallel.

First, The difference of longitude reduced into minutes, or nautical miles, is $765'$, which is the distance between the meridian sailed from, and the meridian come to, upon the equator; then to find the distance between these meridians on the parallel of $54^{\circ} 20'$, or the distance sailed, it will be, by Cor. 3. of the last article,

As radius ————— 10.00000
is to the co-sine of the lat. — $54^{\circ} 20'$ ——— 9.76572
so are the minutes of diff. long. — 765 ——— 2.88366
to the distance on the parallel ——— 446.1 ——— 2.64938

EXAMPLE II. A degree on the equator being 60 minutes or nautical miles; required the length of a degree on the parallel of $51^{\circ} 32'$.

By Cor. 3. of the last article, it will be
As radius ————— 10.00000
is to the co-sine of the latitude $51^{\circ} 32'$ ——— 9.79383
so are the minutes in 1 degree on the equa. 60 — 1.77815
to ————— 37.32 — 1.57198
the miles answering to a degree on the parallel of $51^{\circ} 32'$

By this problem the following table is constructed, shewing the geographic miles answering to a degree on any parallel of latitude; in which you may observe, that the columns marked at the top with *D.L.* contain the degrees of latitude belonging to each parallel; and the adjacent columns marked at the top, *Miles*, contain the geographic miles answering to a degree upon these parallels.

A Table shewing how many Miles answer to a Degree of Longitude, at every Degree of Latitude.

D.L.	Miles	D.L.	Miles	D.L.	Miles	D.L.	Miles	D.L.	Miles
1	59.99	19	56.73	37	47.92	55	34.41	73	17.54
2	59.97	20	56.38	38	47.28	56	33.55	74	16.63
3	59.92	21	56.01	39	46.62	57	32.68	75	15.72
4	59.86	22	55.63	40	45.95	58	31.75	76	14.81
5	59.77	23	55.23	41	45.28	59	30.95	77	13.90
6	59.67	24	54.81	42	44.95	60	30.00	78	12.48
7	59.56	25	54.38	43	43.88	61	29.09	79	11.45
8	59.42	26	53.93	44	43.16	62	28.17	80	10.42
9	59.26	27	53.46	45	42.43	63	27.24	81	9.38
10	59.08	28	52.97	46	41.68	64	26.30	82	8.35
11	58.89	29	52.47	47	40.92	65	25.36	83	7.32
12	58.68	30	51.96	48	40.15	66	24.41	84	6.28
13	58.46	31	51.43	49	39.36	67	23.45	85	5.23
14	58.22	32	50.88	50	38.57	68	22.48	86	4.18
15	57.95	33	50.32	51	37.76	69	21.50	87	3.14
16	57.67	34	49.74	52	36.94	70	20.52	88	2.09
17	57.37	35	49.15	53	36.11	71	19.54	89	1.05
18	57.06	36	48.54	54	35.26	72	18.55	90	0.00

Though

Though this table does only shew the miles answering to a degree of any parallel, whose latitude consists of a whole number of degrees; yet it may be made to serve for any parallel whose latitude is some number of degrees and minutes, by making the following proportion, *viz.*

As 1 degree, or 60 minutes, is to the difference between the miles answering to a degree in the next greater and next less tabular latitude than that proposed; so the excess of the proposed latitude above the next tabular latitude, to a proportional part; which, subtracted from the miles answering to a degree of longitude in the next less tabular latitude, will give the miles answering to a degree in the proposed latitude.

EXAMPLE. Required to find the miles answering to a degree on the parallel of $56^{\circ} 44'$.

First, The next less parallel of latitude in the table than that proposed, is that of 56° , a degree of which (by the table) is equal to 33.55 miles; and the next greater parallel of latitude in the table, than that proposed, is that of 57° , a degree of which is (by the table) equal to 32.68 miles; the difference of these is 87, and the distance between these parallels is 1 degree or 60 minutes; also the distance between the parallel of 56° , and the proposed parallel of $56^{\circ} 44'$, is 44 minutes: then by the preceding proportion it will be, As 60 is to 87, so is 44 to 628, the difference between a degree on the parallel of 56° and a degree on the parallel of $56^{\circ} 44'$; which therefore taken from 33.55, the miles answering to a degree on the parallel of 56° , leaves 32.912, the miles answering to a degree on the parallel of $56^{\circ} 44'$, as was required.

CASE II. The distance sailed in any parallel of latitude, or the distance between any two places on that parallel, being given; to find the difference of longitude.

EXAMPLE. Suppose a ship in the latitude of $55^{\circ} 36'$ north sails directly east 685.6 miles; required how much she has differed her longitude.

By Cor. 4. Art. 1. of this section, it will be

As the co sine of the lat. — $55^{\circ} 36'$ — 9.75202
is to radius ————— 10.00000
so is the distance sailed — 685.6 — 2.83607
to min. of diff. of long. — 1213 — 3.08405
which reduced into degrees, by dividing by 60, makes $20^{\circ} 13'$, the difference of longitude the ship has made.

This may also be solved by help of the foregoing table, *viz.* by finding from it the miles answering to a degree on the proposed parallel, and dividing with this the given number of miles, the quotient will be the degrees and minutes of difference of longitude required.

Thus in the last example; I find, from the foregoing table, that a degree on the parallel of $55^{\circ} 36'$ is equal to 33.89 miles; by this I divide the proposed number of miles 685.6 and the quotient is 20.13 degrees, *i. e.* $20^{\circ} 13'$, the difference of longitude required.

CASE III. The difference of longitude between two places on the same parallel, and the distance between them, being given; to find the latitude of that parallel.

EXAMPLE. Suppose a ship sails on a certain parallel directly west 624 miles, and then has differed her longi-

tude $18^{\circ} 46'$ or 1126 miles: Required the latitude of the parallel she sailed upon.

By Cor. 3. Art. 1. of this section, it will be,
As the min. of diff. long. — 1126 — 3.05154
is to the distance sailed — 624 — 2.79518
so is radius ————— 10.00000
to the co sine of the lat. $56^{\circ} 21'$ — 9.74364

consequently the latitude of the ship or parallel she sailed upon was $56^{\circ} 21'$.

From what has been said, may be solved the following problems.

PROB. I. Suppose two ships in the latitude of $46^{\circ} 30'$ north, distant asunder 654 miles, sail both directly north 256 miles, and consequently are come to the latitude of $50^{\circ} 46'$ north: Required their distance on that parallel

By Cor. 6. Art. 1. of this Section, it will be,
As the co sine of — $46^{\circ} 30'$ — 9.83781
is to the co sine of — $50^{\circ} 46'$ — 9.80105
so is ————— 654 — 2.81558
to ————— 601 — 2.77882
the distance between the ships when on the parallel of $50^{\circ} 46'$.

PROB. II. Suppose two ships in the latitude of $45^{\circ} 48'$ north, distant 846 miles, sail directly north till the distance between them is 624 miles: Required the latitude come to, and the distance sailed.

By Cor. 5. Art. 1. of this Section, it will be,
As their first distance — 846 — 2.92737
is to their second distance — 624 — 2.79518
so is the co sine of — $45^{\circ} 48'$ — 9.84334
to the co sine — 59, 04 — 9.71115
the latitude of the parallel the ships are come to.

Consequently to find their distance sailed,
From the latitude come to — $59^{\circ} 04'$
subtract the latitude sailed from, — 45, 48
and there remains ————— 13, 16
equal to 796 miles, the difference of latitude or distance sailed.

SECT. 4. OF MIDDLE-LATITUDE SAILING.

WHEN two places lie both on the same parallel, we shewed in the last section, how, from the difference of longitude given, to find the miles of easting or westing between them, & *e contra*. But when two places lie not on the same parallel, then their difference of longitude cannot be reduced to miles of easting or westing on the parallel of either place: for if counted on the parallel of that place that has the greatest latitude, it would be too small; and if on the parallel of that place having the least latitude, it would be too great. Hence the common way of reducing the difference of longitude between two places, lying on different parallels, to miles of easting or westing, & *e contra*, is by counting it on the middle parallel between the places, which is found by adding the latitudes of the two places together, and taking half the sum, which will be the latitude of the middle parallel required. And hence arises the solution of the following cases.

CASE I. The latitudes of two places, and their difference of longitude, given; to find the direct course and distance.

EXAMPLE.

EXAMPLE. Required the direct course and distance between the Lizard in the latitude of $50^{\circ} 00'$ north, and longitude of $5^{\circ} 14'$ west, and St Vincent in the latitude of $17^{\circ} 10'$ N. and longitude of $24^{\circ} 20'$ W.

First, To the latitude of the Lizard — $50^{\circ}, 00' N.$
add the latitude of St Vincent — $17, 10$

The sum is — $67, 10$
Half the sum or latitude of } — $33, 35 N.$
the middle parallel is }
Also the difference of latitude is — $33, 50$
equal to 1970 miles of sailing. Again,
From the longitude of St Vincent — $24, 20 W.$
take the longitude of the Lizard — $05, 14$

there remains — $16, 06$
equal to 1146 min. of diff. of long. west.

Then for the miles of sailing, or departure, it will be, by *Case 1. of Parallel Sailing*,

As radius — 10.00000
is to the co-fine of the } — $33^{\circ} 35'$ — 9.92069
middle parallel }
so is min. diff. of long. — 1146 — 3.05918
to the miles of sailing — 954.7 — 2.97987

And for the course it will be, by *Case 4. of Plain Sailing*,

As the diff. of lat. — 1970 — 3.29447
is to radius — 10.00000
so is the departure — 954.7 — 2.97987
to the tang. of the course $25^{\circ}, 51'$ — 9.68540
which, because it is between south and west, it will be SSW $\frac{1}{2}$ west nearly.

For the distance, it will be, by the same case,

As radius — 10.00000
is to the diff. of lat. — 1970 — 3.29447
so is the secant of the course $25^{\circ}, 51'$ — 10.04579
to the distance — 2189 — 3.54026
whence the direct course and distance from the Lizard to St Vincent is SSW $\frac{1}{2}$ W, 2189 miles.

CASE II. One latitude, course, and distance sailed being given, to find the other latitude and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of $50^{\circ} 00'$ north, sails south $50^{\circ} 06'$ west, 150 miles: Required the latitude the ship has come to, and how much she has differed her longitude.

First, For the difference of latitude, it will be, by *Case 1. of Plain Sailing*,

As radius — 10.00000
is to the distance — 150 — 2.17609
so is the co-fine of the course $50^{\circ}, 06'$ — 9.80716
to the diff. of latitude — 96.22 — 1.98325
equal to $1^{\circ}, 36'$. And since the ship is sailing towards the equator; therefore,
From the latitude she was in — $50^{\circ}, 00'$
take the diff. of latitude — $1, 36$

and there remains — $48, 24$
the latitude she has come to north. Consequently the latitude of the middle parallel will be $49^{\circ} 12'$.

Then for departure or westing it will be, by the same case,

As radius — 10.00000
is to the distance — 150 — 2.17609
so is the fine of the course $50^{\circ} 06'$ — 9.88489
to the departure — 115.1 — 2.06098

As for the difference of longitude, it will be, by *Case 2. of Plain Sailing*.

As the co-fine of the middle parallel $49^{\circ} 12'$ 9.81519
is to radius — 10.00000
so is the departure — 115.1 — 2.06098
to the min. diff. of longitude 176.1 — 2.24579
equal to $2^{\circ} 56'$, which is the difference of longitude the ship has made westerly.

CASE III. Course and difference of latitude given; to find the distance sailed, and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of $53^{\circ} 34'$ north, sails SEbS, till by observation she is found to be in the latitude of $51^{\circ} 12'$, and consequently has differed her latitude $2^{\circ} 22'$ or 142 miles: Required the distance sailed, and the difference of longitude.

First, for the departure, it will be (by *Case 2. of Plain Sailing*.)

As radius — 10.00000
is to the diff. of latitude — 142 — 2.15229
so is the tang. of course — $33^{\circ} 45'$ — 9.82489
to the departure — 94.88 — 1.97718

And for the distance it will be, by the same *Case*,

As radius — 10.00000
is to the diff. of latitude — 142 — 2.15229
so is the secant of the course $33^{\circ} 45'$ — 10.08011
to the distance — 170.8 — 2.23244

Then, since the latitude sailed from was $53^{\circ} 34'$ north, and the latitude come to $51^{\circ} 12'$ north; therefore the middle parallel will be $52^{\circ} 23'$; and consequently, for the difference of longitude, it will be (by *Case 2. of Parallel Sailing*)

As the co-fine of the mid. parallel $52^{\circ} 23'$ 9.78560
is to the departure — 94.88 — 1.97718
so is radius — 10.00000
to min. of diff. of longitude — 155.5 — 2.19158
equal to $2^{\circ} 35'$ the difference of longitude easterly.

CASE IV. Difference of latitude and distance sailed, given; to find the course and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of $43^{\circ} 26'$ north, sails between south and east, 246 miles, and then is found by observation to be in the the latitude of $41^{\circ} 06'$ north: Required the direct course and difference of longitude.

First, For the course, it will be, by *Case 3. of Plain Sailing*.

As the distance — 246 — 2.39094
is to radius — 10.00000
so is the diff. of latitude — 140 — 2.14613
to the co-fine of the course $55^{\circ} 19'$ — 9.75519
which, because the ship sails between south and east, will be south $55^{\circ} 19'$ east, or SEbE nearly.

Then for departure, it will be, by the same *Case*,
As radius — 10.00000
is to the distance — 246 — 2.39094
to

So is the sine of the course 55° 19' — 9.91504
to the departure — 202.3 — 2.30598
Lastly, For the difference of longitude, it will be, by

Case 2. of Parallel Sailing,
As the co-sine of the mid. par. 42° 16' — 9.86924
is to the departure — 302.3 — 2.30598
So is radius — — — 10.00000
to min. of diff. of longitude 273.3 — 2.43674
equal to 4° 33', the difference of longitude easterly.

CASE V. Course and departure given, to find difference of latitude, difference of longitude, and distance failed.

EXAMPLE. Suppose a ship in the latitude of 48° 23' north, sails SW $\frac{1}{2}$ S, till she has made of westing 123 miles: Required the latitude come to, the difference of longitude, and the distance failed.

First, For the distance, it will be, by *Case 6. of Plain Sailing,*

As the sine of the course — 33° 45' — 9.74474
is to the departure — 123 — 2.08991
So is radius — — — 10.00000
to the distance — 221.4 — 2.34517

And for the difference of latitude it will be, by the same *Case,*

As the tang. of course — 33° 45' — 9.82489
is to the departure — 123 — 2.08991
So is radius — — — 10.00000
to the diff. of latitude — 184 — 2.26502

equal to 3° 04': And since the ship is sailing towards the equator, the latitude come to will be 45° 19' north; and consequently the middle parallel will be 46° 51'.

Then to find the difference of longitude, it will be, by

Case 2. of Parallel Sailing,
As the co-sine of mid. par. 46° 51' — 9.83500
is to departure — 123 — 2.08991
So is radius — — — 10.00000
to min. of diff. of longit. — 180 — 2.25491

which is equal to 3° 00', the difference of longitude westerly.

CASE VI. Difference of latitude and departure given, to find course, distance, and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of 46° 37' north, sails between south and east, till she has made of easting 146 miles, and is then found by observation to be in the latitude of 43° 24' north; required the course, distance, and difference of longitude.

First, By *Case 4. of Plain Sailing,* it will be for the course,

As the diff. of latitude — 193 — 2.28556
is to departure — 146 — 2.16137
So is radius — — — 10.00000
to the tang. of the course — 36° 55' — 9.87581

which, because the ship is sailing between south and east, will be south 36° 55' east or SE $\frac{1}{2}$ S $\frac{1}{2}$ east nearly.

For the distance, it will be, by the same *Case,*

As radius — — — 10.00000
is to the diff. of latitude — 193 — 2.28556
So is the secant of the course 36° 55' — 10.09718
to the distance — 241.4 — 2.38274

Then for the difference of longitude, it will be, by *Case 2. of Parallel Sailing,*

Vol. III. No. 84. 2

As the co-sine of the mid. par. 45° 00' — 9.84949
is to the departure — 146 — 2.16137
So is radius — — — 10.00000
to min. of diff. of longitude — 205 — 2.31188
equal to 3° 25', the difference of longitude easterly.

CASE VII. Distance and departure given, to find difference of latitude, course, and difference of longitude.

EXAMPLE. Suppose a ship in the latitude of 33° 40' north, sails between south and east 165 miles, and has then made of easting 112.5 miles; required the difference of latitude, course, and difference of longitude.

First, For the course, it will be, by *Case 5. of Plain Sailing,*

As the distance — 165 — 2.21748
is to radius — — — 10.00000
So is the departure — 102.5 — 2.05115
to the sine of the course 42° 59' — 9.83367
which, because the ship sails between south and east, will be south 42° 59' east or SE $\frac{1}{2}$ E $\frac{1}{2}$ east nearly.

And for the difference of latitude, it will be, by the same *Case,*

As radius — — — 10.00000
is to the distance — 165 — 2.21748
So is the co sine of the course 42° 59' — 9.86436
to the difference of lat. — 120.7 — 2.08184

equal to 2° 00'; consequently the latitude come to will be 31° 40' north, and the latitude of the middle parallel will be 32° 40'. Hence, to find the difference of longitude, it will be, by *Case 2. of Parallel Sailing,*

As the co-sine of the mid. par. 32° 40' — 9.92522
is to the departure — 112.5 — 2.05115
So is radius — — — 10.00000
to min. of diff. of long. — 133.6 — 2.12593

equal to 2° 13' nearly, the difference of longitude easterly.

CASE VIII. Difference of longitude and departure given, to find difference of latitude, course, and distance failed.

EXAMPLE. Suppose a ship in the latitude of 50° 46' north, sails between south and west, till her difference of longitude is 3° 12', and is then found to have departed from her former meridian 126 miles; required the difference of latitude, course, and distance failed.

First, For the latitude she has come to, it will be, by *Case 3. of Parallel Sailing,*

As min. of diff. of long. — 192 — 2.28330
is to departure — 126 — 2.10037
So is radius — — — 10.00000
to the co sine of the mid. par. — 48° 59' — 9.81707

Now since the middle latitude is equal to half the sum of the two latitudes (by Art. 1. of this Sect.) and so the sum of the two latitudes equal to double the middle latitude; it follows, that if from double the middle latitude, we subtract any one of the latitudes, the remainder will be the other. Hence from twice 48° 59', viz. 97° 58' taking 50° 46' the latitude failed from, there remains 47° 12' the latitude come to; consequently the difference of latitude is 3° 34', or 214 minutes.

Then for the course, it will be, by *Case 4. of Plain Sailing,*

As diff. of lat. — 214 — 2.33041
5 B † 13

is to radius ————— 10.00000
 so is the departure — 126 ——— 2.10037
 to the tang. of the course 30° , $29'$ ——— 9.76996
 which, because it is between fourth and west, will be fourth
 30° $29'$ west, or SSW $\frac{1}{2}$ west nearly.

And for the distance, it will be, by the same *Case*,

As radius ————— 10.00000
 is to the diff. of lat. ——— 214 ——— 2.33041
 so is the secant of the course 30° , $29'$ ——— 10.06461
 to the distance ——— 248.4 ——— 2.39502

2 From what has been said, it will be easy to solve a traverse, by the rules of *Middle Latitude Sailing*.

EXAMPLE. Suppose a ship in the latitude of 43° $25'$ north, sails upon the following courses, viz. SWbS 63 miles, SSW $\frac{1}{2}$ W 45 miles, SdE 54 miles, and SWbW 74 miles: Required the latitude the ship has come to, and how far she has differed her longitude.

First, By *Case* 2. of this *Section*. find the difference of latitude and difference of longitude belonging to each course and distance, and they will stand as in the following table.

Courses	Distances	Diff. of Lat.		Diff. of Longit.	
		N	S	E	W
SWbS —	63		52.4		47.85
SSW $\frac{1}{2}$ W —	45		39.7		28.62
SdE —	54		53.0	13.75	
SWbW —	74		41.1		81.08
Diff. of Lat.			186.2		157.55
					13.75
				Diff. of Long. 143.80	

Hence it is plain the ship has differed her latitude 186.2 minutes, or 3° $6'$ and so has come to the latitude of 40° $19'$ north, and has made of difference of longitude 143.8 minutes, or 2° $23'$ $48''$ westerly.

3. This method of sailing, though it be not strictly true, yet it comes very near the truth, as will be evident, by comparing an example wrought by this method with the same wrought by the method delivered in the next *Section*, which is strictly true; and it serves, without any considerable error, in runnings of 450 miles between the equator and parallel of 30 degrees, of 300 miles between that and the parallel of 60 degrees, and of 150 miles as far as there is any occasion, and consequently must be sufficiently exact for 24 hours run.

SECT. 5. OF MERCATOR'S SAILING.

1. THOUGH the meridians do all meet at the pole, and the parallels to the equator do continually decrease, and that in proportion to the co-sines of their latitudes; yet in old sea charts the meridians were drawn parallel to one another, and consequently the parallels of latitude made equal to the equator, and so a degree of longitude on any parallel as large as a degree on the equator: also in these charts the degrees of latitude were still represented (as they are in themselves) equal to each other, and to

those of the equator. By these means the degrees of longitude being increased beyond their just proportion, and the more so the nearer they approach the pole, the degrees of latitude at the same time remaining the same, it is evident places must be very erroneously marked down upon these charts with respect to their latitude and longitude, and consequently their bearing from one another very false.

2. To remedy this inconvenience, so as still to keep the meridians parallel, it is plain we must protract, or lengthen, the degrees of latitude in the same proportion as those of longitude are, that so the proportion in easting and westing may be the same with that of southing and northing, and consequently the bearings of places from one another be the same upon the chart as upon the globe itself.

Let ABD (No. 11.) be a quadrant of a meridian, A the pole, D a point on the equator, AC half the axis, B any point upon the meridian, from which draw BF perpendicular to AC, and BG perpendicular to CD; then BG will be the sine, and BF or CG the co-sine of BD the latitude of the point B; draw D the tangent and CE the secant of the arch CD. It has been demonstrated in Sect. 3. that any arch of a parallel is to the like arch of the equator as the co-sine of the latitude of that parallel is to radius. Thus any arch as a minute on the parallel described by the point B, will be to a minute on the equator as BF or CG is to CD; but since the triangles CGB CDE are similar, therefore CG will be to CD as CB is to CE, i. e. the co-sine of any parallel is to radius as radius is to the secant of the latitude of that parallel. But it has been just now shown, that the co-sine of any parallel is to radius, as the length of any arch as a minute on that parallel is to the length of the like arch on the equator: Therefore the length of any arch as a minute on any parallel, is to the length of the like arch on the equator, as radius is to the secant of the latitude of that parallel; and so the length of any arch, as a minute on the equator, is longer than the like arch of any parallel in the same proportion, as the secant of the latitude of that parallel is to radius. But since in this projection the meridians are parallel, and consequently each parallel of latitude equal to the equator, it is plain the length of any arch as a minute on any parallel, is increased beyond its just proportion, at such rate as the secant of the latitude of that parallel is greater than radius; and therefore to keep up the proportion of northing and southing to that of easting and westing, upon this chart, as it is upon the globe itself, the length of a minute upon the meridian at any parallel must also be increased beyond its just proportion at the same rate, i. e. as the secant of the latitude of that parallel is greater than radius. Thus to find the length of a minute upon the meridian at the latitude of 75 degrees, since a minute of a meridian is every where equal on the globe, and also equal to a minute upon the equator, let it be represented by unity: then making it as radius is to the secant of 75 degrees, so is unity to a fourth number, which is 3.864 nearly; and consequently, by whatever line you represent one minute on the equator of this chart, the length of one minute on the enlarged meridian

meridian at the latitude of 75° degrees, or the distance between the parallel of $75^\circ 00'$ and the parallel of $75^\circ 01'$, will be equal to 3 of these lines, and $\frac{86.4}{3}$ of one of them. By making the same proportion, it will be found, that the length of a minute on the meridian of this chart at the parallel of 60° , or the distance between the parallel of $60^\circ 00'$ and that of $60^\circ 01'$, is equal to two of these lines. After the same manner, the length of a minute on the enlarged meridian may be found at any latitude; and consequently beginning at the equator, and computing the length of every intermediate minute between that and any parallel, the sum of all these shall be the length of a meridian intercepted between the equator and that parallel; and the distance of each degree and minute of latitude from the equator upon the meridian of this chart, computed in minutes of the equator, forms what is commonly called a table of meridional parts.

If the arch BD (No. 11.) represent the latitude of any point B, then (CD being radius) CE will be the secant of that latitude: but it has been shown above, that radius is to the secant of any latitude, as the length of a minute upon the equator is to the length of a minute on the meridian of this chart at that latitude; therefore CD is to CE, as the length of a minute on the equator is to the length of a minute upon the meridian, at the latitude of the point B. Consequently, if the radius CD be taken equal to the length of a minute upon the equator, CE, or the secant of the latitude, will be equal to the length of a minute upon the meridian at that latitude. Therefore, in general, if the length of a minute upon the equator be made radius, the length of a minute upon the enlarged meridian will be every where equal to the secant of the arch contained between it and the equator.

COR. 1. Hence it follows, since the length of every intermediate minute between the equator and any parallel, is equal to the secant of the latitude (the radius being equal to a minute upon the equator) the sum of all these lengths, or the distance of that parallel on the enlarged meridian from the equator, will be equal to the sum of all the secants, to every minute contained between it and the equator.

COR. 2. Consequently the distance between any two parallels on the same side of the equator is equal to the difference of the sums of all the secant contained between the equator and each parallel, and the distance between any two parallels on contrary sides of the equator is equal to the sum of the sums of all the secants contained between the equator and each parallel.

5. By the tables of meridional parts, which may be seen in Paton, and other writers on this subject, may be constructed the nautical chart, commonly called Mercator's chart. Thus, for example, let it be required to make a chart that shall commence at the equator, and reach to the parallel of 60° degrees, and shall contain 80 degrees of longitude.

Draw the line EQ representing the equator, (see No. 12.) then take, from any convenient line of equal parts, 4800 (the number of minutes contained in 80° degrees,) which set off from E to Q, and this will determine the breadth of the chart.

Divide the line EQ into eight equal parts, in the points

10, 20, 30, &c. each containing 10 degrees, and each of these divided into 10 equal parts will give the single degrees upon the equator; then through the points E, 10, 20, &c. drawing lines perpendicular to EQ, these shall be meridians.

From the scale of equal parts take 4527.4 (the meridional parts answering to 60° degrees,) and set that off from E to A and from Q to B, and join AB; then this line will represent the parallel of 60° , and will determine the length of the chart.

Again, from the scale of equal parts take 603.1 (the meridional parts answering to 10 degrees,) and set that off from E to 10 on the line EA; and through the point 10 draw 10, 10, parallel to EQ; and this will be the parallel of 10 degrees. The same way, setting off from E on the line EA, the meridional parts answering to each degree, &c. of latitude, and through the several points drawing lines parallel to EQ, we shall have the several parallels of latitude.

If the chart does not commence from the equator, but is only to serve for a certain distance on the meridian between two given parallels on the same side of the equator; then the meridians are to be drawn as in the last example: and for the parallels of latitude you are to proceed thus, viz. from the meridional parts answering to each point of latitude in your chart, subtract the meridional parts answering to the least latitude, and set off the differences severally, from the parallel of least latitude, upon the two extreme meridians; and the lines joining these points of the meridians shall represent the several parallels upon your chart.

Thus let it be required to draw a chart that shall serve from the latitude of 20 degrees north to 60 degrees north, and that shall contain 80 degrees of longitude.

Having drawn the line DC to represent the parallel of 20 degrees (see No. 12.) and the meridians to it, as in the foregoing example; set off 663.3 (the difference between the meridional parts answering to 30 degrees, and those of 20 degrees) from D to 30, and from C to 30; then join the points 30 and 30 with a right line, and that shall be the parallel of 30. Also set off 1397.6 (the difference between the meridional parts answering to 40 degrees, and those of 20 degrees) from D to 40, and from C to 40, and joining the points 40 and 40 with a right line, that shall be the parallel of 40. And proceeding after the same way, we may draw as many of the intermediate parallels as we have occasion for.

But if the two parallels of latitude that bound the chart, are on the contrary sides of the equator; then draw a line representing the equator and meridians to it, as in the first example; and from the equator set off on each side of it the several parallels contained between it and the given parallels as above, and your chart is finished.

If Mercator's chart, constructed as above, hath its equator extended on each side of the point E 180 degrees, and if the several places on the surface of the earth be there laid down according to their latitudes and longitudes, we shall have what is commonly called Mercator's map of the earth. This map is not to be considered as a similar and just representation of the earth's surface; for in it the

figures

figures of countries are distorted, especially near the poles: but since the degrees of latitude are every where increased in the same proportion as those of longitude are, the bearings between the places will be the same in this chart as on the globe; and the proportions between the latitudes, longitudes, and nautical distances, will also be the same on this chart, as on the globe itself; by which means the several cases of navigation are solved after a most easy manner, and adapted to the meanest capacities.

N. B. Here you must take notice, that in all charts, the upper part is the north side, and the lower part or bottom is the south side; also that part of it towards the right hand is the east, and that towards the left hand the west side of the chart.

6. Since, according to this projection, the meridians are parallel right lines; it is plain, that the rhombs which form always equal angles with the meridians, will be straight lines; which property renders this projection of the earth's surface much more easy and proper for use than any other.

7. This method of projecting the earth's surface upon a plane, was first invented by Mr Edward Wright, but first published by Mercator; and hence the sailing by the chart, was called Mercator's sailing.

8. In No. 13. let A and E represent two places upon Mercator's chart, AC the meridian of A, and CE the parallel of latitude passing through E; draw AE, and set off upon AC the length AB equal to the number of minutes contained in the difference of latitude between the two places, and taken from the same scale of equal parts the chart was made by, or from the equator, or any graduated parallel of the chart, and through B draw BD parallel to CE meeting AE in D. Then AC will be the enlarged difference of latitude, AB the proper difference of latitude, CE the difference of longitude, BD the departure, AE the enlarged distance, and AD the proper distance, between the two places A and E; also the angle BAD will be the course, and AE the rhomb line between them.

9. Now since in the triangle ACE, BD is parallel to one of its sides CE; it is plain the triangles ACE, ABD, will be similar, and consequently the sides proportional. Hence arise the solutions of the several cases in this sailing, which are as follow.

CASE I. The latitudes of two places given, to find the meridional or enlarged difference of latitude between them.

Of this case there are three varieties, viz. either one of the places lies on the equator, or both on the same side of it; or lastly, on different sides.

1. If one of the proposed places lies on the equator, then the meridional difference of latitude is the same with the latitude of the other place, taken from the table of meridional parts.

EXAMPLE. Required the meridional difference of latitude between St Thomas, lying on the equator, and St Antonio in the latitude of $17^{\circ} 20'$ north. I look in the tables for the meridional parts answering to $17^{\circ} 20'$, and find it to be 1056.2, the enlarged difference of latitude required.

2. If the two proposed places be on the same side of

the equator, then the meridional difference of latitude is found by subtracting the meridional parts answering to the least latitude from those answering to the greatest, and the difference is that required.

EXAMPLE. Required the meridional difference of latitude between the Lizard in the latitude of $50^{\circ} 00'$ north, and Antigua in the latitude of $17^{\circ} 30'$ north. From the meridional parts of — $50^{\circ} 00'$ — 3474.5 subtract the meridional parts of $17^{\circ} 30'$ — 1066.7

there remains — — 2407.8
the meridional difference of latitude required.

3. If the places lie on different sides of the equator, then the meridional difference of latitude is found by adding together the meridional parts answering to each latitude, and the sum is that required.

EXAMPLE. Required the meridional difference of latitude between Antigua in the latitude of $17^{\circ} 30'$ north, and Lima in Peru in the latitude of $12^{\circ} 30'$ South.

To the merid. parts answering to $17^{\circ} 30'$ — 1066.7
add these answering to — $12^{\circ} 30'$ — 756.1

the sum is — — 1822.8
the meridional difference of latitude required.

CASE II. The latitudes and longitudes of two places given, to find the direct course and distance between them.

EXAMPLE. Required to find the direct course and distance between the Lizard in the latitude of $50^{\circ} 00'$ north, and Port-Royal in Jamaica in the latitude of $17^{\circ} 40'$; differing in longitude $70^{\circ} 46'$, Port-Royal lying so far to the westward of the Lizard.

PREPARATION.

From the latitude of the Lizard — $50^{\circ} 00'$
subtract the latitude of Port-Royal — $17^{\circ} 40'$

and there remains — — 32, 20
equal to 1940 minutes, the proper difference of latitude,
Then from the meridional parts of $50^{\circ} 00'$ — 3474.5
subtract those of — $17^{\circ} 40'$ — 1077.2

and there remains — — 2397.3
the meridional or enlarged difference of longitude.

GEOMETRICALLY. Draw the line AC (No 14.) representing the meridian of the Lizard at A, and set off from A, upon that line, AE equal to 1940 (from any scale of equal parts) the proper difference of latitude, also AC equal to 2397.3 (from the same scale) the meridional or enlarged difference of longitude. Upon the point C raise CB perpendicular to AC, and make CB equal to 4246 the minutes of difference of longitude.

Join AB, and through E draw ED parallel to BC: so the case is constructed; and AD applied to the same scale of equal parts the other legs were taken from will give the direct distance, and the angle DAE measured by the line of chords will give the course.

By CALCULATION.

For the angle of the course EAD, it will be, (by Rectangular Trigonometry.)

AC : CB :: R : T, BAC, i. e.
As the meridional diff. of lat. 2397.3 — 3.37970

is to the difference of long. — 4246.0 — 3.62798
 so is radius — — — 10.00000
 to the tang. of the direct course $60^{\circ} 33'$ — 10.34828
 which, because Port Royal is southward of the Lizard,
 and the difference of longitude westerly, will be south
 $60^{\circ} 33'$ west, or SW $\frac{1}{2}$ west nearly.

Then for the distance AD, it will be, (by rectangular trigonometry)

$$R : AE :: \text{Sec. } A : AD, i. e.$$

As the radius — — — 10.00000
 is to the proper diff. of lat. — 194° — 3.28780
 so is the secant of the course — $60^{\circ} 33'$ — 10.30833
 to the distance — — — 3945.6 — 3.59613
 consequently the direct course and distance between the
 Lizard and Port-Royal in Jamaica, is south $60^{\circ} 33'$,
 3945.6 miles.

CASE III. Course and distance failed given, to find difference of latitude and difference of longitude.

EXAMPLE. Suppose a ship from the Lizard in the latitude of $50^{\circ} 00'$ north, sails south $35^{\circ} 40'$ west 156 miles. Required the latitude come to, and how much she has altered her longitude.

GEOMETRICALLY. 1. Draw the line BK (No. 15.) representing the meridian of the Lizard at B; from B draw the line BM, making with BK an angle equal to $35^{\circ} 40'$, and upon this line set off BM equal to 156 the given distance, and from M let fall the perpendicular MK upon BK.

Then for BK the proper difference of latitude, it will be, (by rectangular trigonometry,)

$$R : MB :: S, BMK : BK,$$

i. e. As radius — — — 10.00000
 is to the distance — — — 156 — 2.19312
 so is the co-sine of the course $35^{\circ} 40'$ — 9.90978
 to the proper difference of lat. 127 — 2.10290
 equal to $2^{\circ} 07'$; and since the ship is failing from a north latitude towards the south, therefore the latitude come to will be $47^{\circ} 53'$ north. Hence the meridional difference of latitude will be 193.4.

2. Produce BK to D, till BD be equal to 193.4; through D draw DL parallel to MK, meeting DM produced in L; then DL will be the difference of longitude: to find which by calculation, it will be, (by rectangular trigonometry)

$$R : BD :: T, LBD : DL,$$

i. e. As radius — — — 10.00000
 is to the meridional diff. of lat. 193.4 — 2.28646
 so is the tangent of the course $35^{\circ}, 40'$ — 9.85594
 to minutes of diff. of long. — 138.8 — 2.14240
 equal to $2^{\circ} 18' 48''$ the difference of longitude the ship has made westerly.

CASE IV. Given course and both latitudes, viz. the latitude failed from, and the latitude come to; to find the distance failed, and the difference of longitude.

EXAMPLE. Suppose a ship in the latitude of $54^{\circ} 20'$ north, sails south $33^{\circ} 45'$ east, until by observation she is found to be in the latitude of $51^{\circ} 45'$ north; required the distance failed, and the difference of longitude.

GEOMETRICALLY. Draw AB (No. 16.) to represent the meridian of the ship in the first latitude, and set off from A to B 155 the minutes of the proper difference of

latitude, also AG equal to 257.9 the minutes of the enlarged difference of latitude. Through B and G, draw the lines BC and GK perpendicular to AG; also draw AK making with AG an angle of $33^{\circ} 45'$, which will meet the two former lines in the points C and K; so the case is constructed, and AC and GK may be found from the line of equal parts: To find which,

By CALCULATION:

First, For the difference of longitude, it will be, (by rectangular trigonometry,)

$$R : AG :: T, GAK : GK,$$

i. e. As radius — — — 10.00000
 is to the enlarged diff. of lat. — 257.9 — 2.41145
 so is the tang. of the course — $33^{\circ}, 45'$ — 9.82489
 to min. of diff. of longitude — 172.3 — 2.23634
 equal to $2^{\circ} 52' 18''$, the difference of longitude the ship has made easterly.

This might also have been found, by first finding the departure BC (by *Case 2. of Plain Sailing*), and then it would be

AB : BC :: AG : GK, the difference of longitude required.

Then for the direct distance AC, it will be, (by rectangular trigonometry,)

$$R : AB :: \text{Sec. } A : AC,$$

i. e. As radius — — — 10.00000
 is to the proper diff. of lat. — 155 — 2.19033
 so is the secant of the course — $33^{\circ}, 45'$ — 10.08015
 to the direct distance — 186.4 — 2.27048
 consequently the ship has failed south $33^{\circ} 45'$ east 186.4 miles, and has differed her longitude $2^{\circ} 52' 18''$ easterly.

CASE V. Both latitudes, and distance failed, given; to find the direct course, and difference of longitude.

EXAMPLE. Suppose a ship from the latitude of $45^{\circ} 26'$ north, sails between north and east 195 miles, and then by observation she is found to be in the latitude of $48^{\circ} 6'$ north; required the direct course and difference of longitude.

GEOMETRICALLY. Draw AB (No. 17.) equal to 160 the proper difference of latitude, and from the point B raise the perpendicular BD; then take 195 in your compasses, and setting one foot of them in A, with the other cross the line BD in D. Produce AB, till AC be equal to 233.6 the enlarged difference of latitude. Thro' C draw CK parallel to BD, meeting AD produced in K: so the case is constructed; and the angle A may be measured by the line of chords, and CK by the line of equal parts: To find which,

By CALCULATION:

First, For the angle of the course BAD it will be, (by rectangular trigonometry)

$$AB : R :: AD : \text{Sec. } A. i. e.$$

As the proper diff. of lat. — 160 — 2.20412
 is to radius — — — 10.00000
 so is the distance — 195 — 2.29003
 to the secant of the course — $34^{\circ}, 52'$ — 10.08591
 which, because the ship is failing between north and east, will be north $34^{\circ} 52'$ east, or NE $\frac{1}{2}$ N $1^{\circ} 7'$ easterly.

Then for the difference of longitude, it will be, (by rectangular trigonometry,)

R : AC :: T, A : CK.

i. e. As radius ————— 10.00000
 is to the merid. diff. of lat. — 233.6 — 2.36847
 so is the tang. of the course — 34°, 52' — 9.84307
 to min. of diff. of longitude — 162.8 — 2.21154
 equal to 2° 42' 48", the difference of longitude easterly.

CASE VI. One latitude, course, and difference of longitude, given; to find the other latitude, and distance failed.

EXAMPLE. Suppose a ship from the latitude of 48° 50' north, sails south 34° 40' west, till her difference of longitude is 2° 44'; required the latitude come to, and the distance failed.

GEOMETRICALLY. 1. Draw AE (No. 18.) to represent the meridian of the ship in the first latitude, and make the angle EAC equal to 34° 40', the angle of the course; then draw EC parallel to AE, at the distance of 164 the minutes of difference of longitude, which will meet AC in the point C. From C let fall upon AE the perpendicular CE; then AE will be the enlarged difference of latitude. To find which by *Calculation*, it will be, (by rectangular trigonometry.)

T, A : R :: CE : AE,

i. e. As the tang. of the course 34°, 40' — 9.83984
 is to the radius ————— 10.00000
 so is min. of diff. longitude — 164 — 2.21484
 to the enlarged diff. of latitude — 237.2 — 2.37500
 and because the ship is sailing from a north latitude southerly, therefore,
 From the merid. parts of }
 the latitude failed from } — 48°, 50' — 3366.9
 take the merid. difference of latitude — 237.2
 and there remains ————— 3129.7
 the meridional parts of the latitude come to, *viz.* 46° 09'.

Hence for the proper difference of latitude,
 From the latitude failed from ————— 48°, 50' N
 take the latitude come to ————— 46, 09 N

and there remains ————— 2, 41
 equal to 161, the minutes of difference of latitude.

2. Set off upon AE the length AD equal to 161 the proper difference of latitude, and through D draw DB parallel to CE; then AB will be the direct distance. To find which by *Calculation*, it will be, by rectangular trigonometry,

R : AD :: Sec. A : AB.

i. e. As radius ————— 10.00000
 is to the proper diff. of latitude 161 2.20683
 so is the secant of the course 34°, 40' 10.08488
 to the direct distance ————— 195.8 — 2.29171

CASE VII. One latitude, course, and departure, given; to find the other latitude, distance failed, and difference of longitude.

EXAMPLE. Suppose a ship sails from the latitude of 54° 36' north, south 42° 33' east, until she has made of departure 116 miles. Required the latitude she is in, her direct distance failed, and how much she has altered her longitude.

GEOMETRICALLY. 1. Having drawn the meridian AB, (No. 19.) make the angle BAD equal to 42° 33'. Draw FD parallel to AB at the distance of 116, which will meet AD in D. Let fall upon AB the perpendicular DB. Then AB will be the proper difference of latitude, and AD the direct distance: To find which by calculation, first, for the distance AD it will be (by rectangular trigonometry)

S, A : BD :: R : AD.

i. e. As the sine of the course 42°, 33' 9.83010
 is to the departure ————— 116 2.06446
 so is radius ————— 10.00000
 to the direct distance ————— 171.5 — 2.23436

Then for the proper difference of latitude, it will be, by rectangular trigonometry.

T, A : BD :: R : AB.

i. e. As the tang. of the course 42°, 33' 9.96281
 is to the departure ————— 116 2.06446
 so is radius ————— 10.00000
 to the proper difference of latitude 126.4 2.10165
 equal to 2° 6'; consequently the ship has come to the latitude of 52° 30' north, and so the meridional difference of latitude will be 212.2.

2. Produce AB to E, till AE be equal to 212.2; and through E draw EC parallel to BD, meeting AD produced in C; then EC will be the difference of longitude; to find which by calculation, it will be, (by rectangular trigonometry)

R : AE :: T, A : EC.

i. e. As radius ————— 10.00000
 is to the merid. diff. of latitude 212.2 2.32675
 so is the tang. of the course 42°, 33' 9.96281
 to the min. of diff. of longitude 194.8 2.28956
 equal to 3° 14' 48", the difference of longitude easterly.

This might have been found otherwise, thus: because the triangles ACE, ADB, are similar; therefore it will be,

AB : BD :: AE : EC.

i. e. As the proper diff. of latitude 126.4 2.10165
 is to the departure ————— 116 2.06446
 so is the enlarged diff. of latitude 212.2 2.32675
 to min. diff. of longitude ————— 194.8 2.28956

CASE VIII. Both latitudes and departure given, to find course, distance, and difference of longitude.

EXAMPLE. Suppose a ship from the latitude of 46° 20' N. sails between south and west, till she has made of departure 126.4 miles; and is then found by observation to be in the latitude of 43° 35' north. Required the course and distance sailed, and difference of longitude.

GEOMETRICALLY. Draw AK (No. 20.) to represent the meridian of the ship in her first latitude; set off upon it AC, equal to 165, the proper difference of latitude. Draw BC perpendicular to AC, equal to 126.4 the departure, and join AB. Set off from A, AK equal to 233.3, the enlarged difference of latitude; and through K draw KD parallel to BC, meeting AB produced in D; so the case is constructed, and DK will be the difference of longitude, AB the distance, and the angle A the course; to find which

BY CALCULATION:

First, For DC the difference of longitude, it will be,
 AC:

AC : CB :: AK : KD.

BD : DE :: BA : AC.

i. e. As the proper diff. of latitude 165 2.21748
is to the departure — 126.4 2.10175
so is the enlarged diff. of latitude — 233.3 2.36791
to min. of diff. longitude — 178.7 2.25218
equal to 2° 58' 42", the difference of longitude westerly.

Then for the course it will be, (by rectangular trigonometry,)

AC : BC :: R : T, A.

i. e. As the proper diff. of latitude 165 2.21748
is to departure — 126.4 2.10175
so is radius — 10.00000
to the tangent of the course 37°, 27' 9.88427
which, because the ship sails between fourth and well,
will be fourth 37° 27' west, or SW½S 6° 30' westerly.

Lastly, For the distance AB, it will be, (by rectangular trigonometry,)

S, A : BC :: R : AB.

i. e. As the sine of the course 37°, 27' — 9.78395
is to the departure — 126.4 — 2.10175
so is radius — 10.00000
to the direct distance — 207.9 — 2.31780

CASE IX. One latitude, distance failed, and departure given ; to find the other latitude, difference of longitude, and course.

EXAMPLE. Suppose a ship in the latitude of 48° 33' north, sails between fourth and east 138 miles, and has then made of departure 112.6. Required the latitude come to, the direct course, and difference of longitude.

GEOMETRICALLY. 1st, Draw BD (No. 21.) for the meridian of the ship at B; and parallel to it draw FE, at the distance of 112.6, the departure. Take 138, the distance, in your compasses, and fixing one point of them in B, with the other cross the line FE in the point E; then join B and E, and from E let fall upon BD the perpendicular ED; so BD will be the proper difference of latitude, and the angle B will be the course; to find which, by calculation,

First, for the course it will be, (by rectangular trigonometry,)

BE : R :: DE : S, B.

i. e. As the distance — 138 — 2.13988
is to radius — 10.00000
so is the departure — 112.6 — 2.05154
to the sine of the course — 54° 41' 9.91166
which, because the ship sails between fourth and east, will be fourth 54° 41' east, or SE 9° 41' easterly.

Then for the difference of latitude, it will be, (by rectangular trigonometry,)

R : BE :: Co-S, B : BD.

i. e. As radius — 10.00000
is to the distance — 138 — 2.13988
so is the co-sine of the course 54° 41' 9.76200
to the difference of latitude 79.8 — 1.90188
equal to 1° 19'. Consequently the ship has come to the latitude of 47° 13'. Hence the meridional difference of latitude will be 117.7.

2dly, Produce B to A, till BA be equal to 117.7; and through A draw AC parallel to DE, meeting BE produced in C; then AC will be the difference of longitude; to find which by calculation, it will be,

i. e. As the proper diff. of latitude 79.8 1.90180
is to the departure — 112.6 2.05154
so is the enlarged diff. of latitude 117.7 2.07078
to the diff. of longitude — 166.1 — 2.22044
equal to 2° 46' 06", the difference of longitude easterly.

9. From what has been said, it will be easy to solve a traverse according to the rules of Mercator's sailing.

EXAMPLE. Suppose a ship at the Lizard in the latitude 50° 00' north, is bound to the Madera in the latitude of 32°, 20' north, the difference of longitude between them being 11° 40', the west end of the Madera lying so much to the westward of the Lizard, and consequently the direct course and distance (by *Case* 2. of this *Sett.*) is fourth 26° 15' west 1181.9 miles; but by reason of the winds she is forced to sail on the following courses (allowance being made for lee-way and variation, &c.) viz. SSW 44 miles, S½W ½ west 36 miles, SW½S 56 miles, and S½E 28 miles. Required the latitude the ship is in, her bearing and distance from the Lizard, and her direct course and distance from the Madera, at the end of these courses.

The geometrical construction of this traverse is performed by laying down the two ports according to construction of *Case* 2. of this *Sett.* and the several courses and distances according to *Case* 3. by which we have the following solution by calculation.

1. Course SSW, distance 44 miles.

For difference of latitude:

As radius — 10.00000
is to the distance — 44 — 1.64345
so the is the co-sine of the course 22°, 30' 9.96562
to the difference of latitude — 40.65 — 1.60907
and since the course is southerly, therefore the latitude come to will be 49° 20' north, and consequently the meridional difference of latitude will be 61.8. Then

For difference of longitude,

As radius — 10.00000
is to the enlarged diff. of lat. 61.8 — 1.79099
so is the tang. of the course 22°, 30' — 9.61722
to min. of diff. of longitude 25.6 — 1.40821

2. Course S½W ½ west, distance 36 miles.

For difference of latitude:

As radius — 10.00000
is to the distance — 36 — 1.55630
so is the co-sine of the course 16°, 52' 9.98099
to the difference of latitude — 34.46 — 1.53720
and since the course is southerly, therefore the latitude come to will be 48° 45'. Hence the meridional difference of latitude will be 53.4. Then,

For difference of longitude:

As radius — 10.00000
is to the enlarged diff. of lat. 53.4 — 1.72754
so is the tan. of the course 16°, 52' — 9.48171
to the difference of longitude 16.19 — 1.20925

3. Course SW½S, distance 56 miles.

For difference of latitude:

As radius — 10.00000
is to the distance — 56 — 1.74819
so is the co-sine of the course 33°, 45' 9.91985

to the difference of latitude — 46 56 1.66804
consequently the latitude come to is $47^{\circ} 59'$, and there-
fore the enlarged difference of latitude will be 69.2.

Then,

For difference of longitude :

As radius ————— 10.00000
is to the enlarged diff. of lat. 69.2 1.84011
so is the tang. of the course $33^{\circ} 45'$ 9.82489
to the difference of longitude 46.24 1.66500

4. Course S δ E, distance 28 miles.

For difference of latitude :

As radius ————— 10.00000
is to the distance — 28 — 1.44716
so is the co-sine of the course $11^{\circ} 15'$ 9.99157
to the difference of latitude 27.46 1.43873
consequently the latitude come to will be $47^{\circ} 31'$;
hence the meridional difference of latitude will be 43.2.

Then,

For difference of longitude :

As radius ————— 10.00000
is to the enlarged diff. of lat. 43.2 1.63548
so is the tang. of the course $11^{\circ} 15'$ 9.29866
to the diff. of longitude 8.59 0.93414

Now these several courses and distances, together with
the difference of latitude and longitude belonging to each
of them, being set down in their proper columns in the
Traverse Table, will stand as follow.

Courses	Distances	Diff. of Lat.				Diff. of Longit.
		N	S	E	W	
SSW —	44 —		40.65 —		25.6 —	
S δ W $\frac{1}{2}$ W —	36 —		34.46 —		16.19 —	
SW $\frac{1}{2}$ S —	56 —		46.56 —		49.24 —	
S δ E —	28 —		27.46 —	8.59 —		
Diff. of Lat.		149.13		8.59		88.03
						8.59
		Diff. of long.				79.44

Hence it is plain that the ship has made of Southing
149.13 minutes, and consequently has come to the lati-
tude of $47^{\circ} 31'$ north, and so the meridional difference
of latitude between that and her first latitude will be
226.1; and since she has made of difference of longitude
79.44 minutes westerly; therefore for the direct course
and distance between the lizard and the ship it will be,
(by *Case 2. of this Section*)

For the direct course :

As the merid. diff. of latitude 226.1 — 2.35430
is to radius ————— 10.00000
so is the difference of longitude 79.44 1.90004
to the tang. of the course — $19^{\circ} 22'$ 9.54593
which because the difference of latitude is southerly, and
the difference of longitude westerly, will be south 19°
 $22'$ west, or S δ W $8^{\circ} 7'$ westerly. Then,

For the direct distance :

As radius ————— 10.00000

is to the proper diff. of lat 149.13 2.17349
so is the secant of the course $19^{\circ} 22'$ 10.02530
to the direct distance — 158 — 2.19879
From the latitude the ship is in $47^{\circ} 31' N$
subtract the lat. of the Madera — $32^{\circ} 20' N$

and there remains ————— 15, 11
equal to 911 minutes, the proper difference of latitude
between the ship and the Madera.

Again, from the merid. parts answering }
to the latitude the ship is in } — 3248.4
Take the meridional parts answering to }
the latitude of the Madera } — 2052.0

and there remains ————— 1196.4
the enlarged difference of latitude between the ship and
the Madera.

Also, from the diff. of long. between }
the Lizard and the Madera } $11^{\circ} 40' W$
Take the difference of long. between }
the Lizard and the ship — 1, 19.43 W

and there remains ————— 10, 20.86 W
equal to 620.56 min. of difference of longitude between
the ship and the Madera westerly.

Then for the direct course and distance between the ship
and the Madera, it will be,

For the direct course :

As the merid. diff. of latitude 1196.4 3.07788
is to radius ————— 10.00000
so is the difference of longitude 620.56 2.79278
to the tang. of the course — $27^{\circ} 25'$ 9.71453

For the direct distance :

As radius ————— 10.00000
is to the proper diff. of latitude 911 2.95952
so is the secant of the course $27^{\circ} 25'$ 10.05174
to the direct distance 1027 3.01126

10. It is very common, in working a day's reckoning
at sea, to find the difference of latitude and departure to
each course and distance; and adding all the departures
together, and all the differences of latitudes for the whole
departure, and difference of latitude made good that day,
from thence (by *Case 8. of this Section*) to find the dif-
ference of longitude, &c. made good that day. Now that
this method is false, will evidently appear, if we consider
that the same departure reckoned on two different paral-
lels will give unequal differences of longitude; and con-
sequently, when several departures are compounded to-
gether and reckoned on the same parallel, the difference of
longitude resulting from that cannot be the same with
the sum of the differences of longitude resulting from the
several departures on different parallels; and therefore
we have chosen, in the last example of a traverse, to find
the difference of longitude answering to each particular
course and distance, the sum of which must be the true
difference of longitude made good by the ship on these
several courses and distances.

11. We shewed, at *Art. 5. of this Section*, how to
construct a *Mercator's Chart*; and now we shall proceed
to its several uses, contained in the following problems.

PROB. 1. Let it be required to lay down a place upon

the chart, its latitude, and the difference of longitude between it and some known place upon the chart being given.

EXAMPLE. Let the known place be the Lizard lying on the parallel of $50^{\circ} 00'$ north, and the place to be laid down St Katharines on the east coast of America, differing in longitude from the Lizard $42^{\circ} 36'$, lying so much to the westward of it.

Let L represent the Lizard on the chart, (see No. 12.) lying on the parallel of $50^{\circ} 00'$ north, its meridian. Set off AE from E upon the equator EQ $42^{\circ} 36'$, towards Q, which will reach from E to F. Through F draw the meridian FG, and this will be the meridian of St Katharines; then set off from Q to H upon the graduated meridian QB, 28 degrees; and through H draw the parallel of latitude HM, which will meet the former meridian in K, the place upon the chart required.

PROB. II. Given two places upon the chart, to find their difference of latitude and difference of longitude.

Through the two places draw parallels of latitude; then the distance between these parallels numbered in degrees and minutes upon the graduated meridian will be the difference of latitude required; and through the two places drawing meridians, the distance between these, counted in degrees and minutes on the equator or any graduated parallel, will be the difference of longitude required.

PROB. III. To find the bearing of one place from another upon the chart.

EXAMPLE. Required the bearing of St Katharines at K (see No. 12.) from the Lizard at L.

Draw the meridian of the Lizard AE, and join K and L with the right line KL; then by the line of chords measuring the angle KLE, and with that entering the tables, we shall have the thing required.

This may also be done, by having compasses drawn on the chart (suppose at two of its corners); then lay the edge of a ruler over the two places, and let fall a perpendicular, or take the nearest distance from the centre of the compass next the first place, to the ruler's edge; then with this distance in your compasses, slide them along by the ruler's edge, keeping one foot of them close to the ruler, and the other as near as you can judge perpendicular to it, which will describe the rhomb required.

PROB. IV. To find the distance between two given places upon the chart.

This problem admits of four cases, according to the situation of the two places with respect to one another.

CASE I. When the given places lie both upon the equator.

In this case their distance is found by converting the degrees of difference of longitude intercepted between them into minutes.

CASE II. When the two places lie both on the same meridian.

Draw the parallels of those places; and the degrees upon the graduated meridian, intercepted between those parallels, reduced to minutes, give the distance required.

CASE III. When the two places lie on the same parallel.

EXAMPLE. Required to find the distance between the points K and N, (see No. 12.) both lying on the parallel

of $28^{\circ} 00'$ north. Take from your scale the chord of 60° or radius in your compasses, and with that extent on KN as a base make the isosceles triangle KFN; then take from the line of lines the co-sine of the latitude, or sine of 72° and set that off from P to S and T. Join S and T with the right line ST, and that applied to the graduated equator will give the degrees and minutes upon it equal to the distance; which, converted into minutes, will be the distance required.

The reason of this is evident from the fiction of *Parallel Sailing*; for it has been there demonstrated, that radius is to the co-sine of any parallel, as the length of any arch on the equator, to the length of the same arch on that parallel. Now in this chart KN is the distance of the meridians of the two places K and N upon the equator; and since, in the triangle PNK, ST is the parallel to KN, therefore PN:PT::NK:TS. Consequently TS will be the distance of the two places K and N upon the parallel of 28° .

If the parallel the two places lie on be not far from the equator, and they not far asunder; then their distance may be found thus. Take the distance between them in your compasses, and apply that to the graduated meridian, so as the one foot may be as many minutes above, as the other is below the given parallel; and the degrees and minutes intercepted, reduced to minutes, will give the distance.

Or it may also be found thus. Take the length of a degree on the meridian at the given parallel, and turn that over on the parallel from the one place to the other, as oft as you can; then as oft as that extent is contained between the places, so many times 60 miles will be contained in the distance between them.

CASE IV. When the places differ both in longitude and latitude.

EXAMPLE. Suppose it were required to find the distance between the two places *a* and *c* upon the chart. By

PROB. II. Find the difference of latitude between them; and take that in your compasses from the graduated equator, which set off on the meridian of *a*, from *a* to *b*; then through *b* draw *bc* parallel to *de*; and taking *ac* in your compasses, apply it to the graduated equator, and it will shew the degrees and minutes contained in the distance required, which multiplied by 60 will give the miles of distance.

The reason of this is evident from *Art. 8.* of this *Sett.* for it is plain *ad* is the enlarged difference of latitude, and *ab* the proper; consequently *ac* the enlarged distance, and *ac* the proper.

PROB. V. To lay down a place upon the chart, its latitude and bearing from some known place upon the chart being known, or (which is the same) having the course and difference of latitude that a ship has made, to lay down the running of the ship, and find her place upon the chart.

EXAMPLE. A ship from the Lizard in the latitude of $50^{\circ} 00'$ north, sails SSW till she has differed her latitude $36^{\circ} 40'$. Required her place upon the chart

Count from the Lizard at L, on the graduated meridian downwards (because the course is southerly) $36^{\circ} 40'$ to *g*;

through which draw a parallel of latitude, which will be the parallel the ship is in; then from *L* draw a SSW line *Lf*, cutting the former parallel in *f*, and this will be the ship's place upon the chart.

PROB. VI. One latitude, course, and distance, failed, given; to lay down the running of the ship, and find her place upon the chart.

EXAMPLE. Suppose a ship at *a* in the latitude of $20^{\circ} 00'$ north, sails north $37^{\circ} 20'$, east 191 miles: Required the ship's place upon the chart.

Having drawn the meridian and parallel of the place *a*, set off the rhomb line *ac*, making with *ab* an angle of $37^{\circ} 20'$; and upon it set off 191 from *a* to *c*; through *c* draw the parallel *cb*; and taking *ab* in your compasses, apply it to the graduated equator, and observe the number of degrees it contains; then count the same number of degrees on the graduated meridian from *C* to *h*, and through *h* draw the parallel *he*, which will cut *ac* produced in the point *e*, the ship's place required.

PROB. VII. Both latitudes and distance failed, given; to find the ship's place upon the chart.

EXAMPLE. Suppose a ship sails from *a*, in the latitude of $20^{\circ} 00'$ north, between north and east 191 miles, and is then in the latitude of $45^{\circ} 00'$ north: Required the ship's place upon the chart.

Draw *de* the parallel of 45° , and set off upon the meridian of *a* upwards, *ab* equal to the proper difference of latitude taken from the equator or graduated parallel. Through *b* draw *bc* parallel to *de*; then with 191 in your compasses, fixing one foot of them in *a*, with the other cross *bc* in *c*. Join *a* and *c* with the right line *ac*; which produced will meet *de* in *e*, the ship's place required.

PROB. VIII. One latitude, course and difference of longitude, given; to find the ship's place upon the chart.

EXAMPLE. Suppose a ship from the Lizard in the latitude of $50^{\circ} 00'$ north, sails SW $\frac{1}{2}$ W, till her difference of longitude is $42^{\circ} 36'$: Required the ship's place upon the chart.

Having drawn *AE* the meridian of the Lizard at *L*, count from *E* to *F* upon the equator $42^{\circ} 36'$; and through *F* draw the meridian *EG*; then from *L* draw the SW $\frac{1}{2}$ W line *LK*, and where this meets *FG*, as at *K*, will be the ship's place required.

PROB. IX. One latitude, course, and departure, given; to find the ship's place upon the chart.

EXAMPLE. Suppose a ship at *a* in the latitude of $20^{\circ} 00'$ north, sails north $37^{\circ} 20'$ east, till she has made of departure 116 miles: Required the ship's place upon the chart.

Having drawn the meridian of *a*, at the distance of 116, draw parallel to it the meridian *kl*. Draw the rhomb line *ac*, which will meet *kl* in some point *c*; then through *c* draw the parallel *cb*, and *a* *b* will be the proper difference of latitude, and *b* *c* the departure. Take *a* *b* in your compasses, and apply it to the equator or graduated parallel; then observe the number of degrees it contains, and count so many on the graduated meridian from *C* upwards to *b*. Through *b* draw the parallel *be*, which will meet *ac* produced in some point as *e*, which is the ship's place upon the chart.

PROB. X. One latitude, distance, and departure, given; to find the ship's place upon the chart.

EXAMPLE. Suppose a ship at *a* in the latitude of $20^{\circ} 00'$ north, sails 191 miles between north and east, and then is found to have made of departure 116 miles: Required the ship's place upon the chart.

Having drawn the meridian and parallel of the place *a*, set off upon the parallel *am* equal to 116, and through *m* draw the meridian *kl*. Take the given distance 191 in your compasses; setting one foot of them in *a*, with the other cross *kl* in *c*. Join *ac*, and through *c* draw the parallel *cb*; so *cb* will be the departure, and *ab* the proper difference of latitude; then proceeding with this, as in the foregoing problem, you will find the ship's place to be *e*.

PROB. XI. The latitude failed from, difference of latitude, and departure, given; to find the ship's place upon the chart.

EXAMPLE. Suppose a ship from *a* in the latitude of $20^{\circ} 00'$ north, sails between north and east, till she be in the latitude of $45^{\circ} 00'$ north, and is then found to have made of departure 116 miles: Required the ship's place upon the chart.

Having drawn the meridian of *a*, set off upon it, from *a* to *b*, 25 degrees, (taken from the equator or graduated parallel,) the proper difference of latitude; then through *b* draw the parallel *bc*, and make *bc* equal to 116 the departure, and join *a* *c*. Count from the parallel of *a* on the graduated meridian upwards to *b* 25 degrees, and through *b* draw the parallel *be*, which will meet *ac* produced in some point *e*, and this will be the place of the ship required.

12. In the section of *Plain Sailing* it is plain that the terms *meridional distance*, *departure*, and *difference of longitude*, were synonymous, constantly signifying the same thing; which evidently followed from the supposition of the earth's surface being projected on a plane, in which the meridians were made parallel, and the degrees of latitude equal to one another and to those of the equator. But since it has been demonstrated (in this section) that if, in the projection of the earth's surface upon a plane, the meridians be made parallel, the degrees of latitude must be unequal, still increasing the nearer they come to the pole. It follows that these terms must denote lines really different from one another.

SECT. 6. OF OBLIQUE SAILING.

THE questions that may be proposed on this head being innumerable, we shall only give a few of the most useful.

PROB. 1. Coasting along the shore. I saw a cape bear from me NNE; then I stood away NW $\frac{1}{2}$ W 20 miles, and I observed the same cape to bear from me NE $\frac{1}{2}$ E. Required the distance of the ship from the cape at each station.

GEOMETRICALLY. Draw the circle NWSE (No. 22.) to represent the compass, NS the meridian, and WE the east and west line, and let *C* be the place of the ship in her first station; then from *C* set off upon the NW $\frac{1}{2}$ W line, *CA* 20 miles, and *A* will be the place of the ship in her second station.

From

From C draw the NNE line CB, and from A draw AB parallel to the NEAE line CD, which will meet CB in B the place of the cape, and CB will be the distance of from the ship in its first station, and AB the distance in the second : to find which,

By CALCULATION;

In the triangle ABC are given AC, equal to 20 miles; the angle ACB, equal to $78^{\circ} 45'$, the distance between the NNE and NW $\frac{1}{2}$ W lines; also the angle ABC, equal to BCD, equal to $33^{\circ} 45'$, the distance between the NNE and NB $\frac{1}{2}$ E lines; and consequently the angle A, equal to $67^{\circ} 3'$.

Hence for CB, the distance of the cape from the ship in her first station, it will be (by oblique trigonometry)

$$S. ABC : AC :: S. BAC : CB,$$

i. e. As the sine of the angle B $33^{\circ} 45'$ 9.74473
is to the distance run AC — 20 — 1.30103
so is the sine of BAC — $67^{\circ} 3'$ 9.96562
to CB — 33.26 1.52191
the distance of the cape from the ship at the first station.

Then for AB, it will be, by oblique trigonometry,

$$S. ABC : AC :: S. ACB : AB.$$

i. e. As the sine of B — $33^{\circ} 45'$ 9.74474
is to AC — 20 — 1.30103
so is the sine of C — $78^{\circ} 45'$ 9.99157
to AB — 35.31 1.54786
the distance of the ship from the cape at her second station.

PROB. II. Coasting along the shore, I saw two headlands; the first bore from me NEAE 17 miles, the other SSW miles. Required the bearing and distance of these headlands from one another.

GEOMETRICALLY. Having drawn the compass NWSE (No. 23.) let C represent the place of the ship; set off upon the NEAE line CA 17 miles from C to A, and upon the SSW line CB 20 miles from C to B, and join AB: then A will be the first headland, and B the second; also AB will be their distance, and the angle A will be the bearing from the NEAE line: to find which

By CALCULATION;

In the triangle ACB are given, AC 17, CB 20, and the angle ACB equal to $101^{\circ} 15'$, the distance between the NEAE and SSW lines. Hence (by oblique angular trigonometry) it will be

As the sum of the sides AC and CB 37 1.56820
is to their difference — 3 0.47712
so is the tang. of $\frac{1}{2}$ the sum } $39^{\circ} 22 \frac{1}{2}'$ 9.91417
of the angles A and B }
to the tang. of half their diff. 3, 49 8.82309
consequently the angle A will be $43^{\circ} 11'$, and the angle B $35^{\circ} 34'$; also the bearing of B from A will be S $\frac{1}{2}$ W $1^{\circ} 49'$ westerly, and the bearing of A from B will be NAE $1^{\circ} 49'$ easterly.

Then for the distance AB, it will be, by oblique-angular trigonometry,

$$S. A : CB :: S. C : AB.$$

i. e. As the sine of A $43^{\circ} 11'$ 9.83527
is to CB — 20 — 1.30103
so is the sine of C — $101^{\circ} 15'$ — 9.99157
to AB — 28.67 — 1.45733
the distance between the two headlands.

PROB. III. Coasting along the shore, I saw two headlands; the first bore from me NW $\frac{1}{2}$ N, and the second NNE; then standing away E $\frac{1}{2}$ N $\frac{1}{2}$ northerly 20 miles, I found the 6th bore from me WNW $\frac{1}{2}$ westerly, and the second N $\frac{1}{2}$ W $\frac{1}{2}$ westerly. Required the bearing and distance of these two headlands.

GEOMETRICALLY. Having drawn the compass NWSE (No. 24.) let C represent the first place of the ship; from which draw the NW $\frac{1}{2}$ N line CB, and the NNE line CD, also the E $\frac{1}{2}$ N $\frac{1}{2}$ N line CA, which make equal to 20. From A draw AB parallel to the WNW $\frac{1}{2}$ W line, and AD parallel to the N $\frac{1}{2}$ W $\frac{1}{2}$ W meeting the two first lines in the points B and D; then B will be the first and D the second headlands. Join the points B and D, and BD will be the distance between them, and the angle CDB the bearing from the NNE line: to find which

By CALCULATION;

1. In the triangle ABC are given the angle BCA, equal to $104^{\circ} 04'$, the distance between the NW $\frac{1}{2}$ N line, and the ENE $\frac{1}{2}$ E line; the angle BAC, equal to $36^{\circ} 34'$, the distance between the WSW $\frac{1}{2}$ W line and the WNW $\frac{1}{2}$ W line; the angle ABC equal to $39^{\circ} 22'$, the distance between the ESE $\frac{1}{2}$ E line; and the SW $\frac{1}{2}$ S line, also the side CA equal to 20 miles: whence for CB, it will be (by oblique trigonometry)

As the sine of CBA — $39^{\circ} 22'$ — 9.80228
is to AC — 20 — 1.30103
so is the sine of CAB — $36^{\circ} 34'$ — 9.77507
to CB — 18.79 — 1.27382
the distance between the first headland and the ship in her first station.

2. In the triangle ACD, are given the angle ACD, equal to $47^{\circ} 49'$, the distance between the ENE $\frac{1}{2}$ E line, and the NNE line; the angle CAD, equal to $92^{\circ} 49'$, the distance between the WSW $\frac{1}{2}$ W line; and the NW $\frac{1}{2}$ W line, the angle CDA equal to $39^{\circ} 22'$, the distance between the SSW line and the S $\frac{1}{2}$ E $\frac{1}{2}$ E line; also the leg CA equal to 20.

Hence for CD, it will be (by oblique trigonometry)
As the sine CAD — $39^{\circ} 22'$ — 9.80228
is to AC — 20 — 1.30103
so is the sine of CAD — $92^{\circ} 34'$ — 9.99960
to CD — 31.5 — 1.49835
the distance between the second headland and the ship in her first station.

3. In the triangle BCD are given BC 18.79, CD 31.5, and the angle BCD equal to $56^{\circ} 15'$, the distance between the NW $\frac{1}{2}$ N line and the NNE line.

Hence for the angle CDB, it will be (by oblique trigonometry)

As the sum of the sides — 50.29 — 1.70148
is to the difference of sides 12.71 — 1.10415
so is tangent of $\frac{1}{2}$ sum } $61^{\circ} 51'$ — 10.27189
of the unknown angles }
to tang. of half their diff. $25^{\circ} 18'$ — 9.67458
consequently the angle CBD is $87^{\circ} 10'$, and the angle CDB $36^{\circ} 35'$. Hence the bearing of the first headland from the second will be S $59^{\circ} 8'$ W or SW $\frac{1}{2}$ W $\frac{1}{2}$ W nearly; and for the distance between them, it will be,
As the sine of BDC — $36^{\circ} 35'$ — 9.77524
is to BC — 18.79 — 1.27382

so is the sine of BCD — $56^{\circ} 15'$ — 991985
to BD — — — 26 21 — 141843
the distance between the two headlands.

This, and the first problem, are of great use in drawing the plot of any harbour, or laying down any sea coast.

Suppose a ship that makes her way good within 6 $\frac{1}{2}$ points of the wind, at north, is bound to a port bearing east 86 miles distance from her: Required the course and distance upon each tack, to gain the intended port.

GEOMETRICALLY. Having drawn the compass NE SW, (No. 25.) let C represent the ship's place, and set off upon the east line CA 86 miles, so A will be the intended port. Draw CD and CB on each side of the north line at 6 $\frac{1}{2}$ points distance from it, and through A draw AB parallel to CD meeting CB in B; then the ENE $\frac{1}{2}$ E line CB, will be the course of the ship upon the starboard tack, and CB its distance on that tack; also the ESE $\frac{1}{2}$ E line Ab, will be the course on the larboard tack, and BA the distance on that tack: to find which

By CALCULATION;

In the triangle ABC are given, the angle ACB, equal to $16^{\circ} 53'$, the distance between the east and ENE $\frac{1}{2}$ E line; the angle CBA, equal to $146^{\circ} 14'$, the distance between the ENE $\frac{1}{2}$ E and the WNW $\frac{1}{2}$ W lines; the angle BAC equal to $16^{\circ} 53'$, the distance between the east and ESE $\frac{1}{2}$ E lines; also AC 86 miles.

Hence since the angle at A and C are equal, the legs CB and BA will likewise be equal; to find either of which (suppose CB) it will be (by oblique angled trigonometry.)

As the sine of B	—	$146^{\circ} 14'$	—	9 74493
is to AC	—	86	—	1.93450
so is the sine of A	—	$16^{\circ} 53'$	—	9.46303
to CB	—	44.94	—	1.65260

the distance the ship must sail on each tack.

There is a great variety of useful questions of this nature that may be proposed; but the nature of them being better understood by practice at sea, we shall leave them, and go on to *Current Sailing*.

SECT. 7. Concerning CURRENTS, and how to make proper allowances.

I. CURRENTS are certain settings of the stream, by which all bodies (as ships, &c.) moving therein, are compelled to alter their course or velocity, or both; and submit to the motion impressed upon them by the current.

CASE I. If the current sets just with the course of the ship, (*i. e.*) moves on the same rhomb with it; then the motion of the ship is increased, by as much as is the drift or velocity of the current.

EXAMPLE. Suppose a ship sails SEBS at the rate of 6 miles an hour, in a current that sets SEBS 2 miles an hour: Required her true rate of sailing.

Here it is evident that the ship's true rate of sailing will be 8 miles an hour.

CASE II. If the current sets directly against the ship's course, then the motion of the ship is lessened by as much as is the velocity of the current.

EXAMPLE. Suppose a ship sails SSW at the rate of 10 miles an hour, in a current that sets NNE 6 miles an hour. Required the ship's true rate of sailing.

Here it is evident that the ship's true rate of sailing will be 4 miles an hour. Hence it is plain.

COR. I. If the velocity of the current be less than the velocity of the ship, then the ship will get so much ahead as is the difference of these velocities.

COR. II. If the velocity of the current be greater than that of the ship, then the ship will fall so much a stern as is the difference of these velocities.

COR. III. Lastly, If the velocity of the current be equal to that of the ship, then the ship will stand still; the one velocity destroying the other.

CASE III. If the current thwarts the course of the ship, then it not only lessens or augments her velocity, but gives her a new direction compounded of the course the steers, and the setting of the current, as is manifest from the following

LEMMA. If a body at A (No. 26.) be impelled by two forces at the same time, the one in the direction AB capable to carry that body from A to B in a certain space of time, and the other in the direction AD capable to carry it from A to D in the same time; complete the parallelogram ABCD, and draw the diagonal AC; then the body at A agitated by these two forces together, will move along the line BC, and will be in the point C at the end of the time in which it would have moved along AD or AB with the forces separately applied.

Hence the solution of the following examples will be evident.

EXAMPLE I. Suppose a ship sails (by the compass) directly south 96 miles in 24 hours, in a current that sets east 45 miles in the same time. Required the ship's true course and distance.

GEOMETRICALLY. Draw AD (see No. 26.) to represent the south and north line of the ship at A, which make equal to 96; from D draw DC perpendicular to AD, equal to 45; and join AC. Then C will be the ship's true place, AC her true distance, and the angle CAD the true course. To find which

By CALCULATION:

First, For the true course DAC, it will be, (by rectangular trigonometry,)

As the apparent distance AD	—	96	—	1.98227
is to the current's motion DC	—	45	—	1.65321
so is radius	—	—	—	10.00000
to the tangent of the true	}	—	$25^{\circ} 07'$	9 67094
course DAC				

consequently the ship's true course is S $25^{\circ} 07'$ E, or SSE $2^{\circ} 37'$, easterly.

Then for the true distance AC, it will be, (by rectangular trigonometry,)

As the sine of the course A	—	$25^{\circ} 07'$	—	9 62784
is to the departure DC	—	45	—	1.65321
so is radius	—	—	—	10.00000
to the true distance AC	—	106	—	2.02537

EXAMPLE. Suppose a ship sails SE 120 miles in 20 hours, in a current that sets WbN at the rate of 2 miles an hour: Required the ship's true course and distance sailed in that time.

GEOMETRICALLY. Having drawn the compass NESW (No 27.) let C represent the place the ship failed from; draw the SE line CA, which make equal to 120; then will A be the place the ship caped at.

From A draw AB parallel to the W^N line CD, equal to 40, the motion of the current in 20 hours, and join CB; then B will be the ship's true place at the end of 20 hours, CB her true distance, and the angle SCB her true course. To find which

By CALCULATION;

In the triangle ABC, are given CA 120, AB 40, and the angle CAB equal to $34^{\circ} 45'$, the distance between the E^SS and SE lines, to find the angles B and C, and the side CB.

First, For the angles C and B, it will be, (by oblique trigonometry)

As the sum of the sides CA and AB	160	—	2.20412
is to their difference	80	—	1.90309
so is the tang. of half the sum			
of the angles B and C	$73^{\circ} 07'$		10.51783
to the tang. of half their diff.	$59, 45$		10.21680

consequently the angle B will be $131^{\circ} 52'$, and the angle ACB $14^{\circ} 23'$. Hence the true course is S 30° , $37'$ E, or SSE $2^{\circ} 07'$ easterly.

Then for the true distance CB, it will be, (by oblique trigonometry)

As the sine of B	$131^{\circ} 52'$	—	9.87198
is to AC	120	—	2.07918
so is the sine of A	$33^{\circ} 45'$	—	9.74474
to the true distance CB	89.53	—	1.95194

EXAMPLE III. Suppose a ship coming out from sea in the night, has sight of Scilly light, bearing NE^N distance 4 leagues, it being then flood tide setting ENE 2 miles an hour, and the ship running after the rate of 5 miles an hour. Required upon what course and how far she must fail to hit the Lizard, which bears from Scilly E^SS distance 17 leagues.

GEOMETRICALLY. Having drawn the compass NESW (No. 28.) let A represent the ship's place at sea, and draw the NE^N line AS, which make equal to 12 miles, so S will represent Scilly.

From S draw SL equal to 51 miles, and parallel to the E^SS line; then L will represent the Lizard.

From L draw LC parallel to the ENE line, equal to 2 miles, and from C draw CD equal to 5 miles meeting AL in D; then from A draw AB parallel to CD meeting LC produced in B; and AB will be the required distance, and SAB the true course. To find which

By CALCULATION;

In the triangle ASL are given the side AS equal to 12 miles, the side SL equal to 51, and the angle ASL equal to $118^{\circ} 07'$, the distance between the NE^N and W^N lines; to find the angles SAL and SLA. Consequently, (by oblique trigonometry,) it will be,

As the sum of the sides AS and SL	63	—	1.79934
is to their difference	39	—	1.59106
so is the tang. of half the sum			
of the angles SAL and SLA	$30^{\circ} 56'$		9.77763
to the tang. of half their diff.	$20^{\circ} 21'$		9.56935

Vox. III. N^o. 85.

consequently the angle SAL, will be $51^{\circ} 17'$, and for the direct bearing of the Lizard from the ship will be N $85^{\circ} 02'$ E, or E^NN $6^{\circ} 17'$ E; and for the distance AL, it will be (by oblique trigonometry,)

As the sine of SAL	$51^{\circ} 17'$	—	9.89223
is to SL	51	—	1.70757
so is the sine of ASL	$118^{\circ} 07'$	—	9.94546
to AL	57.65	—	1.76080

the distance between the ship and the Lizard.

Again, in the triangle DLC, are given the angle L equal to $17^{\circ} 32'$, the distance between the ENE and N $85^{\circ} 02'$ E lines; the side LC, equal to 2 miles, the current's drift in an hour; and the side CD, equal to 5 miles, the ship's run in the same time. Hence for the angle D, it will be (by oblique trigonometry,)

As the ship's run in 1 hour DC	5	—	0.69897
is to the sine of L	$17^{\circ} 32'$	—	9.47894
so is the current's drift LC	2	—	0.30103
to the sine of D	$6^{\circ} 55'$	—	9.08100

consequently since by construction the angle LAB is equal to the angle LDC, the course the ship must steer is S $88^{\circ} 03'$ E.

Then for the distance AB, it will be (by oblique trigonometry,)

As the sine of B	$155^{\circ} 33'$	—	9.61689
is to AL	57.65	—	1.76080
so is the sine of L	$17^{\circ} 32'$	—	9.47894
to AB	41.96	—	1.62285

consequently, since the ship is sailing at the rate of 5 miles an hour, it follows, that in sailing $8^h 24^m$ S $88^{\circ} 03'$ E, she will arrive at the Lizard.

EXAMPLE IV. A ship from a certain headland in the latitude of $34^{\circ} 00'$ north, sails SE^S 12 miles in three hours, in a current that sets between north and east; and then the same headland is found to bear WNW, and the ship to be in the latitude of $33^{\circ} 52'$ north. Required the setting and drift of the current.

GEOMETRICALLY. Having drawn the compass NESW (No. 29.) let A represent the place of the ship, and draw the SE^S line AB equal to 12 miles, also the ESE line AC.

Set off from A upon the meridian AD, equal to 8 miles, the difference of latitude, and through D draw DC parallel to the east and west line WE, meeting AC in C. Join C and B with the right line BC; then C will be the ship's place, the angle ABC the setting of the current from the SE^S line, and the line BC will be the drift of the current in 3 hours. To find which

By CALCULATION:

In the triangle ADC, right angled at D, are given the difference of latitude AD equal to 8 miles, the angle DAC equal to $67^{\circ} 30'$. Whence for AC, the distance the ship has sailed, it will be

As radius	—	—	10.00000
is to the diff. of latitude AD	8	—	0.90309
so is the secant of the course			
DAC	$67^{\circ} 30'$		10.41716
to the distance run AC	20.9	—	1.32025

Again, in the triangle ABC, are given AB equal to 5 E

†

12

12 miles, AC equal to 20.9, and the angle BAC equal to $33^{\circ} 45'$, the distance between the SEBS and ESE lines. Whence for the angle at B, it will be,
 As the sum of the sides AC and AB 32.9 1.51720
 is to their difference ——— 8.9 — 0.94930
 so is the tang. of half the
 sum of the angles B and C } $73^{\circ} 07'$ — 10.51806
 to tang. of $\frac{1}{2}$ their diff. — $41^{\circ} 43'$ — 9.95025
 consequently the angle B is $114^{\circ} 51'$, and so the setting
 of the current will be N $81^{\circ} 06'$ E or E $8^{\circ} 21'$ E.
 Then for BC the current's drift in 3 hours, it will be,
 As the sine of B — $114^{\circ} 51'$ — 9.92700
 is to the distance run AC 20.9 ——— 1.32025
 so is the sine of A — $33^{\circ} 45'$ — 9.74474
 to BC ——— 12.8 — 1.10719
 the current's drift in 3 hours, and consequently the current sets E $8^{\circ} 21'$ E 4.266 miles an hour.

SECT. 8. Concerning the VARIATION of the COMPASS, and how to find it from the true and observed AMPLITUDES or AZIMUTHS of the sun.

1. THE variation of the compass is how far the north or south point of the needle stands from the true south or north point of the horizon towards the east or west; or it is an arch of the horizon intercepted between the meridian of the place of observation and the magnetic meridian.

2. It is absolutely necessary to know the variation of the compass at sea, in order to correct the ship's course; for since the ship's course is directed by the compass, it is evident that if the compass be wrong the true course will differ from the observed, and consequently the whole reckoning differ from the truth.

3. The sun's true amplitude is an arch of the horizon comprehended between the true east or west point thereof, and the centre of the sun at rising or setting; or it is the number of degrees, &c. that the centre of the sun is distant from the true east or west point of the horizon, towards the south or north.

4. The sun's magnetic amplitude is the number of degrees that the centre of the sun is from the east or west point of the compass, towards the south or north point of the same at rising or setting.

5. Having the declination of the sun, together with the latitude of the place of observation, we may from thence find the sun's true amplitude, by the following astronomic proposition, *viz.*

As the co-sine of the latitude
 is to the radius

So is the sine of the sun's declination
 to the sine of the sun's true amplitude
 which will be north or south according as the sun's declination is north or south.

EXAMPLE. Required the sun's true amplitude in the latitude of $41^{\circ} 50'$ north, on the 23d day of April 1731.

First, I find (from the tables of the sun's declination) that the sun's declination the 23d of April is $15^{\circ} 54'$ north; then for the true amplitude, it will be, by the former analogy.

As the co sine of the lat. $41^{\circ} 50'$ — 9.87221
 is to radius ——— 10.00000

so is the sine of the decl. $15^{\circ} 54'$ — 9.43767
 to the sine of the amplit. $21^{\circ} 35'$ — 9.56548
 which is north, because the declination is north at that time; and consequently, in the latitude of $41^{\circ} 50'$ north, the sun rises on the 23d of April $21^{\circ} 35'$ from the east part of the horizon towards the north, and sets so much from the west the same way.

6. The sun's true azimuth is the arch of the horizon intercepted between the meridian and the vertical circle passing through the centre of the sun at the time of observation.

7. The sun's magnetic azimuth is the arch of the horizon intercepted between the magnetic meridian and the vertical, passing through the sun.

8. Having the latitude of the place of observation, together with the sun's declination and altitude at the time of observation, we may find his true azimuth after the following method, *viz.*

Make it,

As the tangent of half the complement of the latitude is to the tangent of half the sum of the distance of the sun from the pole and complement of the altitude

So is the tangent of half the difference between the distance of the sun from the pole and complement of the altitude

To the tangent of a fourth arch
 which fourth arch added to half the complement of the latitude will give a fifth arch, and this fifth arch lessened by the complement of the latitude will give a sixth arch.

Then make it

As the radius

is to the tangent of the altitude

so is the tangent of the sixth arch

to the co sine of the sun's azimuth

which is to be counted from the fourth or north, to the east or west, according as the sun is situated with respect to the place of observation.

If the latitude of the place and declination of the sun be both north or both south, then the declination taken from 90° will give the sun's distance from the pole; but if the latitude and declination be on contrary sides of the equator, then the declination added to 90° will give the sun's distance from the nearest pole to the place of observation.

EXAMPLE. In the latitude of $51^{\circ} 32'$ north, the sun having $19^{\circ} 39'$ north declination, his altitude was found by observation to be $38^{\circ} 18'$: Required the azimuth.

By the first of the foregoing analogies, it will be

As the tangent of $\frac{1}{2}$ the complement of the latitude } $19^{\circ} 14'$ 9.54269

is to the tangent of $\frac{1}{2}$ the sum of the distance of the sun from the pole and complement of the altitude — } $61^{\circ} 01$ 10.25655

so is the tangent of half their difference — } $9^{\circ} 19$ 7.21499

to the tang. of a 4th arch $40^{\circ} 20'$ 9.92885
 which fourth arch $40^{\circ} 20'$, added to $19^{\circ} 14'$ half the complement of the latitude, give a fifth arch $59^{\circ} 34'$; and this fifth arch lessened by $38^{\circ} 28'$, the complement of the latitude, gives the sixth arch $21^{\circ} 06'$; then for the

the azimuth, it will be, by the second of the preceding analogies,

As radius ————— 10.00000
is to the tang. of the altitude 38°, 18' 9.89749
so is the tang. of the sixth arch 21°, 06' — 9.58644
to the co-sine of the azimuth 72°, 15' — 9.48393
which, because the latitude is north and the sun south of the place of observation, must be counted from the south towards the east or west; and consequently, if the altitude of the sun was taken in the morning, the azimuth will be S 72° 15' E, or ESE 4° 45' E; but if the altitude was taken in the afternoon, the azimuth will be S 72° 15' W, or WSW 4° 45' westerly.

g. Having found the sun's true amplitude or azimuth by the preceding analogies, and his magnetic amplitude or azimuth by observation, it is evident, if they agree, there is no variation; but if they disagree, then if the true and observed amplitudes at the rising or setting of the sun be both of the same name, *i. e.* either both north, or both south, their difference is the variation; but if they be of different names, *i. e.* one north and the other south, their sum is the variation. Again, if the true and observed azimuth be both of the same name, *i. e.* either both east or both west, their difference is the variation; but if they be of different names, their sum is the variation: And to know whether the variation is easterly, observe this general rule, *viz.*

Let the observer's face be turned to the sun: then if the true amplitude or azimuth be to the right hand of the observed, the variation is easterly; but if it be to the left, westerly.

To explain which, let NESW (No. 30.) represent a compass, and suppose the sun is really E δ S at the time of observation, but the observer sees him off the east point of the compass, and so the true amplitude or azimuth of the sun is to the right of the magnetic or observed; here it is evident that the E δ S point of the compass ought to lie where the east point is, and so the north where the N δ W is; consequently the north point of the compass is a point too far east, *i. e.* the variation in this case is easterly. The same will hold when the amplitude or azimuth is taken on the west side of the meridian.

Again, let the true amplitude or azimuth be to the left hand of the observed. Thus, suppose the sun is really E δ N at the time of observation, but the observer sees him off the east point of the compass, and so the true amplitude or azimuth to the left of the observed: Here it is evident that the E δ N point of the compass ought to stand where the east point is, and so the north where the N δ E point is; consequently the north point of the compass lies a point too far westerly, so in this case the variation is west. The same will hold when the sun is observed on the west side of the meridian.

EXAMPLE I. Suppose the sun's true amplitude at rising is found to be E 14 $\frac{1}{2}$ 20' N, but by the compass it is found to be E 26° 12': Required the variation, and which way it is.

Since they are both the same way, therefore
From the magnetic amplitude ——— E 26°, 12' N.

take the true amplitude ——— E 14, 20 N.

and there remains the variation ——— 11, 52 E.
which is easterly, because in this case the true amplitude is the right of the observed.

EXAMPLE II. Suppose the sun's true amplitude at setting is W 34° 26' S, and his magnetic amplitude W 23° 13' S: Required the variation, and which way it is.

Since they lie both the same way, therefore
From the sun's true amplitude — W 34°, 26' S.
take his magnetic amplitude — W 23, 13 S.

there remains the variation ——— 11, 13 W.
which is westerly, because the true amplitude, in this case, is to the left hand of the observed.

EXAMPLE III. Suppose the sun's true altitude at rising is found to be 13° 24' N, and his magnetic E 12° 32' S: Required the variation, and which way it lies.

Since the true and observed amplitudes lie different ways, therefore

To the true amplitude ——— E 13°, 24' N.
add the magnetic amplitude ——— E 12, 32 S.

the sum is the variation ——— 25, 56 W.
which is westerly, because the true amplitude is, in this case, to the left of the observed.

EXAMPLE IV. Suppose the sun's true altitude at setting is found to be W 8° 24' N, but his magnetic amplitude is W 10° 13' S: Required the variation.

To the true amplitude ——— W 8°, 24' N.
add the magnetic ——— W 10, 13 S.

the sum is the variation ——— 18, 37 E.
which is easterly, because the true amplitude is to the right of the observed.

EXAMPLE V. Suppose the sun's true azimuth at the time of observation, is found to be N 86° 40' E, but by the compass it is N 73° 24' E: Required the variation, and which way it lies.

From the sun's true azimuth, ——— N 86°, 40' E.
take the magnetical, ——— N 73, 24 E.

there remains the variation, ——— 13, 16 E.
which is easterly, because the true azimuth is to the right of the observed.

EXAMPLE VI. Suppose the sun's true azimuth is S 3° 24' E. and the magnetical S 4° 36' W: Required the variation, and which way it lies.

To the true azimuth ——— S 3°, 24' E.
add the magnetical azimuth ——— S 4, 36 W.

the sum is the variation ——— 8, 00 W.
which is westerly, because the true azimuth is, in this case, to the left of the observed.

10. The variation of the compass was first observed at London, in the year 1580, to be 11° 15' easterly, and in the year 1622 it was 6° 0' E; also in the year 1634, it was 4° 05' E, still decreasing, and the needle approaching the true meridian, till it coincided with it, and then there was no variation; after which, the variation

tion began to be westerly; and in the year 1672, it was observed to be $2^{\circ} 30'$ W; also in the year 1683, it was $4^{\circ} 30'$ W; and since that time the variation still continues at London to increase westerly; but how far it will go that way, time and observations will probably be the only means to discover.

Again, at Paris, in the year 1640, the variation was $3^{\circ} 00'$ E; and in the year 1666, there was no variation; but in the year 1681, it was $2^{\circ} 30'$ W, and still continues to go westerly.

In short, from observations made in different parts of the world, it appears, that in different places the variation differs both as to its quantity and denomination, it being east in one place, and west in another; the true cause and theory of which, for want of a sufficient number of observations, has not as yet been fully explained.

SECT. 9. *The METHOD of keeping a JOURNAL at sea; and how to correct it, by making proper allowances for the leeway, variation, &c.*

1. **LEE-WAY** is the angle that the rhomb bline, upon which the ship endeavours to sail, makes with the rhomb she really sails upon. This is occasioned by the force of the wind or surge of the sea, when she lies to the windward, or is close hauled, which causes her to fall off and glide side-ways from the point of the compass she aims at. Thus let NESW (No. 31.) represent the compass; and suppose a ship at C aims at, or endeavours to sail upon, the rhomb Ca; but by the force of the wind, and surge of the sea, she is obliged to fall off, and make her way good upon the rhomb Cb; then the angle aCb is the leeway; and if that angle be equal to one point, the ship is said to make one point lee way; and if equal to two points, the ship is said to make two points lee way, &c.

2. The quantity of this angle is very uncertain, because some ships, with the same quantity of sail, and with the same gale, will make more lee-way than others; it depending much upon the mould and trim of the ship, and the quantity of water that she draws. The common allowances that are generally made for the lee-way, are as follow.

1. If a ship be close hauled, has all her sails set, the water smooth, and a moderate gale of wind, she is then supposed to make little or no lee-way.

2. If it blow so fresh as to cause the small sails be handed, it is usual to allow one point.

3. If it blow so hard that the top sails must be close reefed, then the common allowance is two points for lee-way.

4. If one top sail must be handed, then the ship is supposed to make between two and three points lee way.

5. When both top-sails must be handed, then the allowance is about four points for lee-way.

6. If blows so hard, as to occasion the fore-course to be handed, the allowance is between $5\frac{1}{2}$ and 6 points.

7. When both main and fore-courses must be handed, then 6 or $6\frac{1}{2}$ points are commonly allowed for lee-way.

8. When the mizen is handed, and the ship is trying a hull, she is then commonly allowed about 7 points for lee-way.

3. Though these rules are such as are generally made

use of, yet since the lee-way depends much upon the mould and trim of the ship, it is evident that they cannot exactly serve to every ship; and therefore the best way is to find it by observation: Thus, let the ship's wake be set by a compass in the poop, and the opposite rumb is the true course made good by the ship; then the difference between this and the course given by the compass in the binnacle, is the lee-way required. If the ship be within sight of land; then the lee-way may be exactly found by observing a point on the land which continues to bear the same way, and the distance between the point of the compass it lies upon and the point the ship aims at will be the lee-way. Thus suppose a ship at C, is lying up NWb, towards A; but instead of keeping that course, she is carried on the NNE line CB, and consequently the point B continues to bear the same way from the ship: Here it is evident, that the angle ACB, or the distance between the NW line that the ship aims at, and the NNE line that the ship really sails upon, will be the lee-way.

4. Having the course steered, and the lee-way, given; we may from thence find the true course by the following method, *viz.* Let your face be turned directly to the windward; and if the ship have her larboard tacks on board, count the lee way from the course steered towards the right hand; but if the starboard tacks be on board, then count it from the course steered towards the left hand. Thus, suppose the wind at north, and the ship lies up within 6 points of the wind, with her larboard tacks on board, making one point lee way; here it is plain, that the course steered is ENE, and the true course EN; also suppose the wind is at NNW, and the ship lies up within $6\frac{1}{2}$ points of the wind with her starboard tack on board, making $1\frac{1}{2}$ point lee way; it is evident that the true course, in this case, is WSW.

5. We have shewed, in the last section, how to find the variation of the compass; and from what has been said there, we have this general rule for finding the ship's true course, having the course steered and the variation given, *viz.* Let your face be turned towards the point of the compass upon which the ship is steered; and if the variation be easterly, count the quantity of it from the course steered towards the right hand; but if westerly, towards the left hand; and the course thus found is the true course steered. Thus, suppose the course steered is N δ E, and the variation one point easterly; then the true course steered will be NNE: Also suppose the course steered is NE δ E, and the variation one point westerly; then in this case, the true course will be NE; and so of others.

Hence, by knowing the lee-way variation, and course steered, we may from thence find the ship's true course; but if there be a current under foot, then that must be tried, and proper allowances made for it, as has been shown in the section concerning *Currents*, from thence to find the true course.

6. After making all the proper allowances for finding the ship's true course, and making as just an estimate of the distance as we can; yet by reason of the many accidents that attend a ship in a day's running, such as different rates of sailing between the times of heaving the log,

the

the want of due care at the helm by not keeping her steady, but suffering her to yaw and fall off; sudden storms, when no account can be kept, &c.; the latitude by account frequently differs from the latitude by observation; and when that happens, it is evident there must be some error in the reckoning; to discover which, and where it lies, and also how to correct the reckoning, you may observe the following rules.

1st, If the ship sail near the meridian, or within 2 or 3 points thereof; then if the latitude by account disagrees with the latitude by observation, it is most likely that the error lies in the distance run; for it is plain that in this case it will require a very sensible error in the course to make any considerable error in the difference of latitude, which cannot well happen if due care be taken at the helm, and proper allowances be made for the lee-way, variation, and currents. Consequently if the course be pretty near the truth, and the error in the distance run regularly through the whole, we may, from the latitude obtained by observation, correct the distance and departure by account, by the following analogies, viz.

As the difference of latitude by account
is to the true difference of latitude,
so is the departure by account
to the true departure,
and so is the direct distance by account
to the true direct distance.

The reason of this is plain: for let AB (No. 33.) denote the meridian of the ship at A, and suppose the ship sails upon the rhomb AE near the meridian, till by account she is found in C, and consequently her difference of latitude by account is AB; but by observation she is found in the parallel ED, and so her true difference of latitude is AD, her true distance AE, and her true departure DE; then since the triangles ABC ADE are similar, it will be AB : AD :: BC : DE, and AB : AD :: AC : AE.

EXAMPLE. Suppose a ship from the latitude of $45^{\circ} 20'$ north, after having sailed upon several courses near the meridian for 24 hours, her difference of latitude is computed to be upon the whole 95 miles southerly, and her departure 34 miles easterly; but by observation she is found to be in the latitude of $43^{\circ} 10'$ north, and consequently her true difference of latitude is 130 miles southerly; then for the true departure, it will be, As the difference of latitude by account 95 is to the true difference of latitude 130, so is the departure by account 34 to the true departure 46.52, and so is the distance by account 100.9 to the true distance 138.

2dly, If the courses are for the most part near the parallel of east and west, and the direct course be within $5\frac{1}{2}$ or 6 points of the meridian; then if the latitude by account differs from the observed latitude, it is most probable that the error lies in the course, or distance, or perhaps both; for in this case it is evident, the departure by account will be very nearly true; and thence by the help of this, and the true difference of latitude, may the true course and distance be readily found by *Case 4. of Plain Sailing*.

EXAMPLE. Suppose a ship from the latitude of $43^{\circ} 50'$ north, after having sailed upon several courses near the parallel of east and west, for the space of 24 hours, is found by dead reckoning to be in the latitude of $42^{\circ} 45'$ north, and to have made 160 miles of westing; but by a good observation the ship is found to be in the latitude of $42^{\circ} 35'$ north: Required the true course, and direct distance sailed.

With the true difference of latitude 75 miles, and departure 160 miles, we shall find (by *Case 4. of Plain Sailing*) the true course to be $S 64^{\circ} 53' W$, and the direct distance 176.7 miles.

3dly, If the courses are for the most part near the middle of the quadrant, and the direct course within 2 and 6 points of the meridian; then the error may be either in the course, or in the distance, or in both, which will cause an error both in the difference of latitude and departure; to correct which, having found the true difference of latitude by observation, with this, and the direct distance by dead reckoning, find a new departure (by *Case 3. of Plain Sailing*;) then half the sum of this departure, and that by dead reckoning, will be nearly equal to the true departure; and consequently with this, and the true difference of latitude, we may (by *Case 4. of Plain Sailing*) find the true course and distance.

EXAMPLE. Suppose a ship from the latitude of $44^{\circ} 38'$ north, sails between south and east upon several courses, near the middle of the quadrant, for the space of 24 hours, and is then found by dead reckoning to be in the latitude of $42^{\circ} 15'$ north, and to have made of easting 136 miles; but by observation she is found to be in the latitude of $42^{\circ} 04'$ north: Required her true course and distance.

With the true distance of latitude 154 miles, and the direct distance by dead reckoning 197.4, you will find (by *Case 3. of Plain Sailing*) the new departure to be 123.4, and half the sum of this and the departure by dead reckoning will be 123.7 the true departure; then with this, and the true difference of latitude, you will find (by *Case 4. of Plain Sailing*) the true course to be $S 39^{\circ} 00' E$, and the direct distance 198.2 miles.

7. In keeping a ship's reckoning at sea, the common method is to take from the log-board the several courses and distances stemmed by the ship last 24 hours, and to transfer these together with the most remarkable occurrences into the log-book, into which also are inserted the courses corrected, and the difference of latitude and difference of longitude made good upon each; then the whole day's work being finished in the log-book, if the latitude by account agree with the latitude by observation, the ship's place will be truly determined; if not, then the reckoning must be corrected according to the preceding rules, and placed in the journal.

The form of the Log-book and Journal, together with an example of 2 days work, you have here subjoined.

Note, To express the days of the week, they commonly use the characters by which the sun and planets are expressed, viz. \odot denotes Sunday, \bullet Monday, \ddagger Tuesday, \S Wednesday, Υ Thursday, ♀ Friday, and ♄ denotes Saturday.

Hence the ship, by account, has come to the latitude of $47^{\circ} 46'$ north, and has differed her longitude $2^{\circ} 5'$ westerly; so this day I have made my way good S $31^{\circ} 31'$ W, distance 157.4 miles.

At noon the Lizard bore from me N $31^{\circ} 31'$ E, distance 157.4 miles; and having observed the latitude, I found it agreed with the latitude by account.

Hence the ship, by account, has come to the latitude of 47° 17' north, and has differed her longitude 49' easterly; consequently she has got 1° 16' to the westward of the Lizard, and has made her way good the last 24 hours 849° 08' E, distance 44.3 miles.

At noon the Lizard bore from me north 17° 7' east, distance 170.6 miles.

This day I had an observation, and found the latitude by account to disagree with the latitude by observation by 11 minutes, I being so much further to the southward than by dead reckoning, which by the third of the preceding rules I correct as in the Journal.

A JOURNAL from the Lizard towards Jamaica in the ship Neptune, J. M. commander.

NAUMACHIA, in antiquity, a show or spectacle among the ancient Romans, representing a sea-fight.

NAUMBURG, a city of Germany, the capital of the county of Sax Naumburg, in Upper Saxony, situated in E. long. 12°, N. lat. 51° 15'.

NAUSEA, in medicine, a reaching, or propensity and endeavour to vomit, arising from a loathing of food, excited by some viscous humour that irritates the stomach.

NAUTICAL PLANISPHERE, a description of the terrestrial globe upon a plane for the use of mariners, more usually called chart.

NAUTILUS, in zoology, a genus belonging to the order of vermes testacea. The shell consists of one spiral valve, divided into several apartments by partitions. There are 17 species, principally distinguished by peculiarities in their shells.

NAVY, the fleet or shipping of a prince or state.

The management of the British navy-royal, under the lord high admiral of Great Britain, is entrusted to principal officers and commissioners of the navy, who hold their places by patent. The principal officers of the navy are four, *viz.* the treasurer, whose business it is to receive money out of the exchequer, and to pay all the charges of the navy, by warrant from the principal officers: comptroller, who attends and compels all payment of wages, is to know the rates of stores, to examine and audit all accounts, &c.: surveyor, who is to know the states of all stores, and see wants supplied; to estimate repairs, charge boatswains, &c. with what stores they receive, and at the end of each voyage to state and audit accounts: clerk of the acts, whose business it is to record all orders, contracts, bills, warrants, &c.

The commissioners of the navy are five: the first executes that part of the comptroller's duty which relates to the comptrolling the victuallers accounts; the second, another part of the said comptroller's duty, relating to the account of the store-keepers of the yard; the third has the direction of the navy at the port of Portsmouth; the fourth has the same at Chatham; and the fifth, at Plymouth.

There are also other commissioners at large, the number more or less according to the exigencies of public affairs; and since the increase of the royal navy, these have several clerks under them, with salaries allowed by the king.

The victualling of the royal navy hath formerly been undertaken by contract; but is now managed by commissioners, who hold their office on Tower-hill, London.

The navy-office is where the whole business concerning the navy is managed by the principal officers and commissioners.

The royal navy of Great Britain is now in a very flourishing state; having been diligently kept up in late reigns, as the natural strength of the kingdom. When it is complete, it is divided into three squadrons, distinguished by the different colours of the flags carried by the respective admirals belonging to the same.

NAXIA, or **NIXIA**, one of the islands of the Archipe-

lago, about an hundred miles in circumference, situated in E. long. 26°, and N. lat. 36° 30'.

NAZARENES, in church history, a name originally given to all Christians in general, on account that Jesus Christ was of the city of Nazareth; but afterwards restrained to a sect of heretics, whose religion consisted of a strange jumble of Judaism and Christianity, observing at the same time the Mosaic law and the several rites of the Christian religion.

NAZARITES, among the Jews, persons who either of themselves, or by their parents, were dedicated to the observation of nazarethship. They were of two sorts: namely, such as were bound to this observance for only a short time, as a week or month; or those who were bound to it all their lives. All that we find peculiar in the latter's way of life, is, that they were to abstain from wine and all intoxicating liquors, and never to shave or cut off the hairs of their heads. The first sort of Nazarites were moreover to avoid all defilement; and if they chanced to contract any pollution before the term was expired, they were obliged to begin afresh. Women as well as men might bind themselves to this vow.

NEALED, among seamen, is used when the sounding is deep water close to the shore; as also when the shore is sandy, clayey, oozy, or foul and rocky ground.

NEAPED. When a ship wants water so that she cannot get out of the harbour, off the ground, or out of the dock, the seamen say she is neaped, or be-neaped.

NEATH, a town of Glamorganshire, in south Wales, situated on the river Neath, near the Bristol channel, twenty-eight miles north west of Landaff.

NEBULY, or **NEBULE**, in heraldry, is when a coat is charged with several little figures, in form of words, running within one another, or when the outline of a bordure, ordinary, &c. is indented or waved, as represented in Plate CXXXIV. fig. 3.

NECESSARY, in a philosophical sense, that which cannot but be, or cannot be otherwise.

NECESSITY, whatever is done by a necessary cause, or a power that is irresistible, in which sense it stands opposed to freedom. See **METAPHYSICS**.

NECK, in anatomy, is that slender part situated between the head and trunk of the body. See **ANATOMY**.

NECKAR, a river of Germany, which rises in the south part of the circle of Swabia, and falls into the Rhine at Manheim.

NECROMANCY, a species of divination, performed by raising the dead, and extorting answers from them. See **DIVINATION**.

NECTAR, among ancient poets, the drink of the fabulous deities of the heathens, in contradistinction from their solid food, which was called ambrosia.

NECTARINE. See **PERSICA**.

NECTARIUM, among botanists. See **BOTANY**, p. 637.

NECYDALIS, in zoology, a genus of insects belonging to the order of coleoptera. The feelers are setaceous; the elytra are shorter and narrower than the wings; and the

the tail is simple. There are eleven species, chiefly distinguished by the size and figure of the elytra.

NEDDHAM, a market-town of Suffolk, situated on the river Orwel, eight miles north-west of Ipswich.

NEEDLE, a very common little instrument or utensil, made of steel, pointed at one end, and pierced at the other, used in sewing embroidery, tapeltry, &c.

Needles make a very considerable article in commerce, though there is scarce any commodity cheaper, the consumption of them being almost incredible. The sizes are from n^o 1. the largest, to n^o 25. the smallest. In the manufacture of needles, German and Hungarian steel are of most repute.

In the making of them, the first thing is to pass the steel through a coal fire, and under a hammer, to bring it out of its square figure into a cylindrical one. This done, it is drawn through a large hole of a wire-drawing iron, and returned into the fire, and drawn through a second hole of the iron, smaller than the first, and thus successively from hole to hole, till it has acquired the degree of fineness required for that species of needles, observing every time it is to be drawn, that it be greased over with lard, to render it more manageable. The steel thus reduced to a fine wire, is cut in pieces of the length of the needles intended. These pieces are flattened at one end on the anvil, in order to form the head and eye; they are then put into the fire, to soften them farther; and thence taken out and pierced at each extreme of the flat part on the anvil, by force of a punchon of well tempered steel, and laid on a leaden block to bring out, with another punchon, the little piece of steel remaining in the eye. The corners are then filed off the square of the heads, and a little cavity filed on each side of the flat of the head; this done, the point is formed with a file, and the whole filed over; they are then laid to heat red hot on a long flat narrow iron, crooked at one end, in a charcoal fire, and when taken out thence are thrown into a basin of cold water to harden. On this operation a good deal depends; too much heat burns them, and too little leaves them soft; the medium is learned by experience. When they are thus hardened, they are laid in an iron shovel on a fire more or less brisk in proportion to the thickness of the needles; taking care to move them from time to time. This serves to temper them, and take off their brittleness; great care here too must be taken of the degree of heat. They are then straightened one after another with the hammer, the coldness of the water used in hardening them having twisted the greatest part of them.

The next process is the polishing them. To do this, they take twelve or fifteen thousand needles, and range them in little heaps against each other on a piece of new buckram sprinkled with emery dust. The needles thus disposed, emery dust is thrown over them, which is again sprinkled with oil of olives; at last the whole is made up into a roll, well bound at both ends. This roll is then laid on a polishing table, and over it a thick plank laden with stones, which two men work backwards and forwards a day and a half, or two days, successively, by which means the roll thus continually agitated by the weight and motion of the plank

over it, the needles withinside being rubbed against each other with oil and emery are infensibly polished. After polishing, they are taken out, and the filth washed off them with hot water and soap: they are then wiped in hot bran, a little moistened, placed with the needles in a round box, suspended in the air by a cord, which is kept stirring till the bran and needles be dry. The needles thus wiped in two or three different brans, are taken out and put in wooden vessels, to have the good separated from those whose points or eyes have been broke either in polishing or wiping; the points are then all turned the same way, and smoothed with an emery-stone turned with a wheel. This operation finishes them, and there remains nothing but to make them into packets of two hundred and fifty each.

Magnetical NEEDLE, in navigation, a needle touched with a loadstone, and sustained on a pivot or centre; on which playing at liberty, it directs itself to certain points in or under the horizon. See **NAVIGATION**, **NEEDLE FISH**. See **SYNGNATHUS**.

NEEDLES, twocapes, or head lands, at the west end of the isle of Wight, which is very difficult to pass on account of the sands and rocks.

NEFASTI DIES, in Roman antiquity, an appellation given to such days wherein it was not allowed to administer justice, usually marked in the calendar by N. or N. P. i. e. nefastus prima, when only nefastus for the first part of it.

NEGAPATAN, a port-town of the hither India, situated on the coast of Coromandel: E. long. 79°, N. lat. 11° 15'.

NEGATION, in logic, an act of the mind affirming one thing to be different from another; as, that the soul is not matter.

NEGATIVE, in general, something that implies a negation: thus we say, negative quantities, negative signs, negative powers, &c. See **METAPHYSICS** and **LOGIC**.

NEGOMBO, a port-town on the west coast of the isle of Ceylon, in the Indian ocean, subject to the Dutch: E. long. 78°, N. lat. 7° 25'.

NEGRAIS, a port town of Pegu, in the further India, situated on the west side of the bay of Bengal: E. lon. 92° 30', N. lat. 17°.

NEGRIL POINT, the most westerly promontory of the island of Jamaica.

NEGROES, properly the inhabitants of Nigritia in Africa, also called blacks and moors; but this name is now given to all the blacks.

The origin of the negroes, and the cause of this remarkable difference from the rest of the human species, has much perplexed the naturalists. Mr. Boyle has observed, that it cannot be produced by the heat of the climate: for though the heat of the sun may darken the colour of the skin, yet experience does not shew that it is sufficient to produce a new blackness, like that of the negroes.

In Africa itself, many nations of Æthiopia are not black, nor were there any blacks originally in the West Indies. In many parts of Asia, under the same parallel with the African region, inhabited by blacks,

the people are but tawny. He adds, that there are negroes in Africa, beyond the southern tropic; and that a river sometimes parts nations, one of which is black and the other only tawny. Dr Barriere alledges that the gall of negroes is black, and being mixed with their blood is deposited between their skin and scarfskin. However, Dr Mitchel of Virginia, in the philosophical transactions, n^o 476, has endeavoured by many learned arguments to prove, that the influence of the sun in hot countries, and the manner of life of their inhabitants, are the remote causes of the colour of negroes, indians, &c. and indeed it would be a strong confirmation of his doctrine, if we would see any people, originally white, become black and woolly by transplantation, or *vice versa*.

Negroes are brought from Guinea, and other coasts of Africa, and sent into the colonies in America, to cultivate tobacco, sugar, indigo, &c. and in Mexico and Peru, to dig in the mines; and this commerce, which is scarce defensible on the foot either of religion or humanity, is now carried on by all the nations that have settlements in the West Indies. Those negroes make the best slaves who are brought from Angola, Senegal, Cape Verd, the river Gambia, the kingdoms of Joloffes, Daniel, Galland, &c.

There are various ways of procuring them: some, to avoid famine, sell themselves, their wives and children, to their princes, or other great men; others are made prisoners of war; and great numbers are seized in excursions made for that very purpose by the petty princes upon one another's territories, in which it is usual to sweep away all without distinction of age or sex.

NEGROES-ISLAND, one of the Philippine islands, in the Indian ocean, subject to Spain; so called, because most of the inhabitants are blacks: E. long. 120°, N. lat. 10°.

NEGROLAND, or **NIGRITIA**, a country of Africa, which lies between 18° west and 15° east longitude, and between 10° and 20° of north latitude, the great river Niger running through it. It is bounded by Zaara, or the desert, on the north, by unknown countries on the east, by Guinea on the south, and by the Atlantic ocean on the west.

NEGROPONT, or **ΕΓΡΙΠΟΣ**, the capital of the island of Negropont, anciently called Euboea, situated in the Archipelago, on the west side of the island; where the strait is so narrow, that it is joined to the continent by a bridge: E. lon. 24° 30', N. lat. 38° 30'.

NEHEMIAH, a canonical book of the Old Testament so called from the name of its author. Nehemiah was born in Babylon, during the captivity, and succeeded Ezra in the government of Judah and Jerusalem. He was a Jew, and was promoted to the office of cup-bearer to Artaxerxes Longimanus king of Persia; when the opportunities he had of being daily in the king's presence, together with the favour of Esther the queen, procured him the favour of being authorized to repair and fortify the city of Jerusalem, in the same manner as it was before its destruction by the Babylonians. On his going to Jerusalem, he fi-

nished the rebuilding of the walls in fifty-two days, and dedicated the gates of the city with great solemnity. He then reformed some abuses which had crept in among his countrymen, particularly the extortion of the usurers, by which the poor were so oppressed as to be forced to sell their lands and children for support: after which he returned to Persia, and came back again with a new commission, by virtue of which he regulated every thing relating both to the state and religion of the Jews. The history of these transactions is the subject of this book.

NELLENBURG, a city of Swabia, in Germany, capital of a county of the same name, situated fifteen miles north of Constance.

NEMÆA, a town in the Morea, thirty miles south of Corinth, where the ancient Nemæan games were celebrated.

NEMÆAN GAMES, were so called from Nemæa, a village between the cities of Cleonæ and Philus, where they were celebrated every third year. The exercises were chariot races, and all the parts of the pentathlon. These games were instituted in memory of Opheltes, or Archemorus, the son of Euphetes and Creusa, and nursed by Hyppipyle; who leaving him in a meadow, while he went to shew the besiegers of Thebes a fountain, at her return found him dead, and a serpent twined about his neck; whence the fountain, before called Langia, was named Archemorus; and the captains, to comfort Hyppipyle, instituted these games. Others ascribe their institution to Hercules, after his victory over the Nemæan lion.

NEMOURS, a city in the isle of France, forty-two miles south of Paris: E. long. 2° 45', N. lat. 48° 17'.

NEOMENIA, or **NOUMENIA**, a festival of the ancient Greeks, at the beginning of every lunar month, which was, as the name imports, observed upon the day of the new moon, in honour of all the gods, but especially Apollo, who was called Neomenios; because the sun is the fountain of light, and whatever distinction of times and seasons may be taken from other planets, yet they are all owing to him as the original of those borrowed rays by which they shine.

NEOPHYTES, *new plants*, a name given by the ancient Christians to those heathens who had newly embraced the faith; such persons being considered as regenerated, or born anew by baptism. The term neophytes has been also used for new priests, or those just admitted into orders, and sometimes for the novices in monasteries. It is still applied to the converts made by the missionaries among the infidels.

NEOTTIA, in botany. See **OPHRYS**.

NEPA, in zoology, a genus of insects belonging to the order of hemiptera. The rostrum is infested; the antennæ are shorter than the thorax; and the hind-feet are hairy, and fitted for swimming. There are seven species.

NEPENTHES, in botany, a plant of the gynandria tetrandria class. The calix consists of four segments; it has no corolla; and the capsule has four cells. There is but one species, a native of Ceylon.

NEPER'S RODS, or **BONES**, an instrument invented by

by J. Neper, baron of Merchiston, in Scotland, whereby the multiplication and division of large numbers are much facilitated.

As to the construction of NEPER'S RODS: suppose the common table of multiplication to be made upon a plate of metal, ivory, or paste-board, and then conceive the several columns (standing downwards from the digits on the head) to be cut asunder; and these are what we call Neper's rods for multiplication. But then there must be a good number of each; for as many times as any figure is in the multiplicand, so many rods of that species (*i. e.* with that figure on the top of it) must we have; though six rods of each species will be sufficient for any example in common affairs: there must also be as many rods of o's.

But before we explain the way of using these rods, there is another thing to be known, *viz.* that the figures on every rod are written in an order different from that in the table. Thus, the little square space or division in which the several products of every column are written, is divided into two parts by a line across from the upper angle on the right to the lower on the left; and if the product is a digit, it is set in the lower division; if it has two places, the first is set in the lower, and the second in the upper division; but the spaces on the top are not divided; also there is a rod of digits, not divided, which is called the index rod, and of this we need but one single rod. See the figure of all the different rods, and the index, separate from one another, in Plate CXXXIV. fig. 1.

Multiplication by NEPER'S RODS. First lay down the index rod; then on the right of it set a rod whose top is the figure in the highest place of the multiplicand; next to this again, set the rod whose top is the next figure of the multiplicand; and so on in order, to the first figure. Then is your multiplicand tabulated for all the nine digits; for in the same line of squares standing against every figure of the index rod, you have the product of that figure, and therefore you have no more to do but to transfer the products and sum them. But in taking out these products from the rods, the order in which the figures stand obliges you to a very easy and small addition; thus, begin to take out the figure in the lower part, or unit's place, of the square of the first rod on the right; add the figure in the upper part of this rod to that in the lower part of the next, and so on, which may be done as fast as you can look on them. To make this practice as clear as possible, take the following example.

Example: To multiply 4768 by 185. Having set the rods together for the number 4768 (*ibid* n° 2.) against 5 in the index, I find this number, by adding according to the rule, - - - 23840

Against 8, this number - - - 38144

Against 3, this number - - - 14304

Total product 1835680

To make the use of the rods yet more regular and easy, they are kept in a flat square box, whose breadth is that of ten rods, and the length that of one rod, as thick as to hold six (or as many as you please) the

capacity of the box being divided into ten cells for the different species of rods. When the rods are put up in the box (each species in its own cell distinguished by the first figure of the rod set before it on the face of the box near the top) as much of every rod stands without the box as shews the first figure of that rod; also upon one of the flat sides without and near the edge, upon the left hand, the index rod is fixed; and along the foot there is a small ledge, so that the rods when applied are laid upon this side, and supported by the ledge, which makes the practice very easy; but in case the multiplicand should have more than nine places, that upper face of the box may be made broader. Some make the rods with four different faces, and figures on each for different purposes.

Division by NEPER'S RODS. First tabulate your divisor; then you have it multiplied by all the digits, out of which you may chuse such convenient divisors as will be next less to the figures in the dividend, and write the index answering in the quotient, and so continually till the work is done. Thus 2179788, divided by 6123, gives in the quotient 356.

Having tabulated the divisor 6123, you see that 6123 cannot be had in 2179; therefore take five places, and on the rods find a number that is equal or next less to 21797, which is 18369; that is, 3 times the divisor; wherefore set 3 in the quotient, and subtract 18369 from the figures above, and there will remain 3428; to which add 8, the next figure of the dividend, and seek again on the rods for it, or the next less, which you will find to be five times; therefore set 5 in the quotient, and subtract 30615 from 34288, and there will remain 3673; to which add 8, the last figure in the dividend, and finding it to be just 6 times the divisor, set six in the quotient.

NEPETA, in botany, a genus of the didynamia gymnospermia class. The intermediate lacinium of the inferior lip is crenated; the margin of the faux is reflected; and the stamina are near each other. There are 14 species, only one of which, *viz.* the catania, nap, or cat-mint, is a native of Britain.

NEPHEW, a term relative to uncle and aunt, signifying a brother or sister's son; who, according to the civil law, is in the third degree of consanguinity; but according to the canon, in the second.

NEPHRITIC, something that relates to the kidneys.

NEPHRITIC WOOD, a wood of a very dense and compact texture, and of a fine grain, brought us from New Spain, in small blocks, in its natural state, and covered with its bark.

This wood is a very good diuretic, and is said to be of

of great use with the Indians in all diseases of the kidneys and bladder, and in suppressions of urine, from whatever cause. It is also recommended in fevers and obstructions of the viscera. The way of taking it, among the Indians, is only an infusion in cold water.

NEPHRITICS, in pharmacy, medicines proper for diseases of the kidneys, especially the stone.

Such particularly are the roots of *althæa*, dog's-grass, asparagus, fago, pellitory of the wall, mallows, pimpinella, red chick-pease, peach kernels, turpentine, the nephritic stone, the nephritic wood, &c. and diuretics.

NEPHRITIS, in medicine, an inflammation of the kidneys. See *MEDICINE*.

NEREIDS, in the pagan theology, sea-nymphs, daughters of Nereus and Doris.

The nereids were esteemed very handsome, inasmuch that Caliope, the wife of Cepheus king of Ethiopia, having triumphed over all the beauties of the age, and daring to vie with the nereids, they were so enraged that they sent a prodigious sea-monster into the country; and to appease them, she was commanded by the oracle to expose her daughter Andromeda, bound to a rock, to be devoured by the monster.

In ancient monuments the nereids are represented riding upon sea-horses, sometimes with an entire human form, and at other times with the tail of a fish.

NEREIS, in zoology, a genus belonging to the order of vermes mollusca. The body is oblong, linear, and fitted for creeping; it is furnished with lateral pincelled tentacula. There are eleven species.

NERICIA, a province of Sweden, bounded by Westmania on the north, by Sunderland on the east, and by Gothland on the south and west.

NERIUM, in botany, a genus of the pentandria monogynia class. The seeds are furnished with plumes; and the tube of the corolla terminates in a lacerated corona. There are four species, none of them natives of Britain.

NERVES, in anatomy. See *ANATOMY*, p. 247.

NEST. See *NIDUS*.

NESTORIANS, a Christian sect, the followers of Nestorius, bishop and patriarch of Constantinople; who, about the year 529, taught that there were two persons in Jesus Christ, the divine and the human, which are united, not hypostatitally or substantially, but in a mystical manner; whence he concluded, that Mary was the mother of Christ and not the mother of God. For this opinion, Nestorius was condemned and deposed by the council of Ephesus; and the decree of this council was confirmed by the emperor Theodosius, who banished the bishop to a monastery.

NETHERLANDS, anciently called Belgia, but since denominated Low Countries or Netherlands from their low situation, are situated between 2° and 7° of east longitude. and between 50° and 53° 30' of north latitude: and are bounded by the German sea on the north, Germany on the east, by Lorrain and France on the south, and by another part of France and the British seas on the west; extending near three hundred

miles in length from north to south, and two hundred miles in breadth from east to west. They consist of seventeen provinces; ten of which are called the Austrian and French Netherlands, and the other seven the United Provinces.

NETTINGS, in a ship, a sort of grates made of small ropes seized together with rope yarn or twine, and fixed on the quarters and in the tops; they are sometimes stretched upon the ledges from the waste trees to the roof trees, from the top of the fore-castle to the poop; and sometimes are laid in the waste of a ship, to serve instead of gratings.

NETTLE, in botany. See *URTICA*.

Dead Nettle. See *LAMIAM*.

NETTLE-TREE. See *CELTIS*.

NETTUNO, a port town of Italy, in the Campagna di Roma; situated on the Mediterranean, thirty miles south-east of Rome.

NEVERS, a city of France, capital of the Nivernois: E. long. 3° 15', N. lat. 46° 50'.

NEUFCHÂTEL, the capital of the counties of Neuchâtel and Vallengin, in Switzerland, which together form one free and independant state, subject to the king of Prussia: E. long. 6° 35', N. lat. 47° 10'.

NEUFCHÂTEL is also a town of Normandy in France, twenty-three miles north-east of Rouen.

NEVIN, or *NEWIN*, a market town of North-Wales eighteen miles south-west of Caernarvon.

NEVIS, one of the Caribbee-islands, divided from the east end of St. Christopher by a narrow channel.

NEURADA, in botany, a genus of the decandria decagynia class. The calix consists of five segments, and the corolla of five leaves; the capsule has ten cells, and ten sharp-pointed seeds. There is but one species, a native of Egypt.

NEURITICS, in pharmacy, medicines good in disorders of the nerves.

NEUROGRAPHY, signifies a description of the nerves.

NEUROPTERA. See *NATURAL HISTORY*, p. 364, col. 1.

NEUSTAT, a city of Germany, thirty miles south of Vienna.

NEUSTAT is also a town of Lower Saxony, sixteen miles north-west of the city of Hanover.

NEUTER, or *NEUTER GENDER*, in grammar, one of the three genders of nouns, so called as being neither masculine nor feminine. See *GRAMMAR*.

NEUTRAL SALTS, among chemists, a sort of salts neither acid nor alkaline, but partaking of the nature of both. See *CHEMISTRY*.

NEUTRALITY, the state of a person or thing that is neuter, or that takes part with neither side.

NEWARK, a borough town of Nottinghamshire, fifteen miles north-east of Nottingham. In sends two members to parliament.

NEWBOROUGH, a market town of Anglesey, fifteen miles north-west of Beaumaris.

NEUBURG, a city of Bavaria. In Germany, twenty eight miles north-east of Augsburg.

NEUBURG is also the name of two other towns of Germany;

(L. B. & Co.

many; one in Swabia, twenty five miles west of Stuttgart; and the other likewise in Swabia, twelve miles north of Basil.

NEWBURY, a market town of Berkshire, fifteen miles west of Reading.

NEWCASTLE, the county-town of Northumberland, situated upon the river Tyne: W. long. $1^{\circ} 10'$, N. lat. 55° . It sends two members to parliament.

NEWCASTLE, a borough town of Staffordshire, ten miles north of Stafford. It sends two members to parliament.

NEWCASTLE, a market town of Caermarthenshire, in South Wales, fifteen miles north of Caermarthen.

NEWEL, in architecture, is the upright post which a pair of winding stairs turn about; this is properly a cylinder of stone which bears on the ground, and is formed by the end of the steps of the winding stairs.

NEWFIDLERS SEA, a lake thirty five miles long, on the north-west part of Upper Hungary.

NEW FOREST, a part of Hampshire, opposite to the Isle of Wight, appropriated by act of parliament for the growth of oaks to build the royal navy. See **FOREST**.

NEFOUNDLAND, a triangular island, three hundred and fifty miles in length from north to south, and two hundred miles in breadth at the base from east to west; situated in North America, between 55° and 61° of west longitude, and between 47° and 52° of north latitude; bounded by the narrow straits of Bellisle on the north, by the Atlantic ocean on the east and south, and by the bay of St. Lawrence on the west. It is subject to England; but the fishing banks on this coast are frequented by most European nations.

NEUHAUSEL, a city of Upper Hungary, situated on the river Neyra: E. long. $18^{\circ} 12'$, N. lat. $48^{\circ} 25'$.

NEWMARK, a city of Transilvania, subject to the house of Austria: E. long. $23^{\circ} 25'$, N. lat. $47^{\circ} 35'$.

NEWMARK is also a town of Germany in the palatinate of Bavaria, thirty miles north-west of Ratibon.

NEWMARKET, a market town, situated both in Cambridgeshire and Suffolk, twelve miles east of Cambridge.

NEWNHAM, a market town, ten miles south-west of Gloucester.

NEWPORT, a port town of Flanders, nine miles south-west of Ostend.

NEWPORT is also a borough town of the Isle of Wight, which sends two members to parliament.

NEWPORT is also a borough of Cornwall, ten miles west of Launceston, which sends two members to parliament.

NEWPORT is also the name of several market towns; one fifteen miles east of Shrewsbury, another eighteen miles south-west of Monmouth, and a third sixteen miles north-east of St. Davids.

NEWPORT PAGNEL, a market-town, sixteen miles north of Ailbury.

NEWSTAT, the name of several towns; one eight miles north of Landau; another fifteen miles south-west of Ratibon; a third in Silesia, fifteen miles south

of Breslaw; a fourth in Hungary, sixty five miles east of Tockay; and a fifth in Moravia, ten miles north of Olmutz.

NEWT, or **EFT**, in zoology. See **LACERTA**.

NEWTON, a borough town, thirty five miles south of Lancaster.

It sends two members to parliament.

NEWTON is also a borough town in the Isle of Wight, twelve miles south of Southampton: it sends two members to parliament.

NEWTONIAN PHILOSOPHY, the doctrine of the universe, and particularly of the heavenly bodies, their laws, affections, &c. as delivered by Sir Isaac Newton. See **ASTRONOMY**, **MECHANICS**, **OPTICS**, &c.

NEYLAND, a market-town of Suffolk, fourteen miles south-west of Ipswich.

NIAGARA, a prodigious cataract in Canada, in North America, between the lakes Erie and Ontario, where the water falls from high rocks 156 feet perpendicular. The mist which this fall occasions may be seen at fifteen miles distance rising as high as the clouds, and forming a beautiful rainbow.

NIBANO, a town of Italy, in the duchy of Parma, thirty five miles west of Parma.

NICARAGUA, a province of Mexico, bounded by the province of Honduras on the north, by the North-sea on the east; by the province of Costarica on the south-east, and by the South sea on the south-west; being 400 miles long, and 120 broad. Nicaragua lake runs through the middle of the province.

NICARIA, one of the islands of the Archipelago, in Asiatic Turkey: E. long. $26^{\circ} 5'$, N. lat. 37° .

NICASTRO, a town of Naples, in the territory of Calabria; E. long. $16^{\circ} 40'$, N. lat. $39^{\circ} 15'$.

NICE, the capital of the county of the same name, situated on the mediterranean, at the mouth of the river Var: E. long. $7^{\circ} 15'$, N. lat. $43^{\circ} 40'$.

NICE is also a town of Asiatic Turkey, fifty miles south-east of Constantinople.

NICHE, in architecture, a hollow sunk into a wall, for the commodious and agreeable placing a statue.

NICOBAR ISLANDS, a cluster of islands situated in the Indian ocean, at the entrance of the gulph of Bengal, between 7° and 10° N. lat.

NICOLAITANS, in church-history, Christian heretics who assumed this name from Nicolas of Antioch; who, being a Gentile by birth, first embraced Judaism, and then Christianity; when his zeal and devotion recommended him to the church of Jerusalem, by whom he was chosen one of the first deacons. Many of the primitive writers believe that Nicolas was rather the occasion than the author of the infamous practices of those who assumed his name, who were expressly condemned by the spirit of God himself, Rev. ii. 6. And indeed their opinions and actions were highly extravagant and criminal. They allowed a community of wives; made no difference between ordinary meats and those offered to idols. According to Eusebius, they subsisted but a short time; but Tertullian says, that they only changed their name, and that their heresies passed into the sect of the Cainians.

St. NICOLAS, a town of Lorrain, ten miles south-east of Nancy, at the mouth of the river *Duna*.

St. Nicolas is also a port-town of Russia situated on the White sea, six miles below Archangel.

St. Nicolas's day, a festival of the Romish church, observed on the 6th of December.

NICOMEDIA, a city of Asiatic Turkey, thirty miles south-east of Constantinople.

NICOPOLIS, a city of European Turkey, situated on the Danube, 100 miles north-west of Adrianople: E. long. 25°, N. lat. 43°.

NICOPPING, a city of Sweden, in the province of Sunderland, fifty miles south of Stockholm.

Nicopping is also the capital of the island *Hullster*, subject to Denmark, and forty eight miles south-west of Copenhagen.

NICOSIA, the capital of the island of Cyprus: E. long. 25°, N. lat. 35°.

NICOTERA, a port town of the kingdom of Naples, thirty miles north-east of Reggio.

NICOTIANA, in botany, a genus of the pentandria monogynia class. The corolla is funnel shaped, with a plaited limbus; the stamina are inclined; and the capsule has two valves and two cells. There are 7 species, all natives of warm climates. The *nicotiana tabacum*, or tobacco, was first brought into Europe about the year 1560, from the island *Tobago* in America. It is cultivated in the following manner.

After sowing the tobacco seeds, the ground is watered every day, and in hot weather covered to prevent its being scorched by the sun; and when the plants are grown to a convenient pitch, they are transplanted into a soil well prepared for their reception: care is also taken to keep this ground clear of weeds, and to pull off the lowest leaves of the plant, that ten or fifteen of the finest leaves may have all the nourishment. When these leaves are ripe, which is known by their breaking when bent, the stalks are cut, and left to dry two or three hours in the sun; after which they are tied together two and two, and hung on ropes under a shade to be dried in the air. And when the leaves are sufficiently dried, they are pulled from off the stalks, and made up in little bundles; which being steeped in seawater, or, for want thereof, in common water, are twisted in manner of ropes, and the twills formed into rolls, by winding them with a kind of mill around a stick: in which condition it is imported into Europe, where it is cut by the tobaccoists for smoking, formed into snuff, and the like. See **SNUFF**.

Besides the tobacco of the West-Indies, there are considerable quantities cultivated in the Levant, the coasts of Greece and the Archipelago, the island of Malta and Italy.

The marks of good twist-tobacco, are a fine shining cut, an agreeable smell, and that it have been well kept. Tobacco is either taken by way of snuff, as a sternutatory; or as a masticatory, by chewing it in the mouth; or by smoking it in a pipe. It is sometimes also taken in little longish pellets put up the nose, where it is found to produce very good effects, to attract a deal of water or pituita, unload the head, resolve catarrhs, and make

a free respiration; for the subtle parts of the tobacco in inspiration, are carried into the trachea and lungs, where they loosen the peccant humours adhering thereto, and promote expectoration. Some have left this tobacco in their noses all night; but this is found to occasion vomiting the next morning. Another thing charged on this way of application, is, that it weakens the sight. When taken in great quantities in the way of snuff, it is found to prejudice the smelling, greatly diminishes the appetite, and in time gives rise to a phthisis. That taken in the way of smoke, dries and damages the brain. Borghi, in a letter to Bartholine, mentions a person who through excess of smoking had dried his brain to that degree, that after his death there was nothing found in his skull but a little black lump, consisting of mere membranes.

Some people use the infusion of tobacco as an emetic; but it is a very dangerous and unjustifiable practice, and often produces violent vomiting, sickness, and stupidity.

Bates and Fuller give some receipts, in which tobacco is an ingredient, with mighty encomiums in asthmatic cases. A strong decoction of tobacco, with proper carminatives and cathartics, given clyster-wise, sometimes proves of good effect in what is usually called the stone-cholic, and also in the iliac passion. A drop or two of the chymical oil of tobacco, being put on the tongue of a cat, produces violent convulsions, and death itself in the space of a minute; yet the same oil used in lint, and applied to the teeth, has been of service in the tooth-ach: though it must be to those that have been used to the taking of tobacco; otherwise, great sickness, reachings, vomitings, &c. happen; and even in no case is the internal use of it warranted by ordinary practice.

A strong decoction of the stalks, with sharp-pointed dock and alum, is said to be of good service, used externally, in cutaneous distempers, especially the itch; some boil them for that purpose in urine. The same is said to be infallible in curing the mange in dogs.

Beat into a mass with vinegar, or brandy, it has been found serviceable for removing hard tumours of the hypochondria.

NICOYA, or **St. Lucas**, a port-town of Mexico, situated on a bay of the South Sea, in 88° W. long. and 10° 15' N. lat.

NICTITATING MEMBRANE, a thin membrane, chiefly found in the bird and fish kind, which covers the eyes of these animals, sheltering them from the dust or too much light; yet is so thin and pellucid, that they can see pretty well through it.

NIDUS, among naturalists, signifies a nest, or proper repository for the eggs of birds, insects, &c. wherein the young of these animals are hatched and nursed.

NIECE, a brother or sister's daughter, which in the civil law is reckoned the third degree of consanguinity.

NIEMEN, or **BEREZINA**, a river of Poland, which rises in Lithuania, and falls into a bay of the Baltic sea, near Memel.

NIEPER, or **BORISTHENES**, a river which rises in the middle of Russia; and running south through Poland, enters

- cross the Russian Ukraïn, separates Little Tartary from Poland Tartary, and falls into the Black Sea near Georgia.
- NIESTAT**, a town of Lower Saxony, in the duchy of Mecklenburg: E. long. $11^{\circ} 26'$, N. lat. $53^{\circ} 40'$.
- NIESTAR** is also a town of Upper Saxony, in the marquisate of Brandenburg, 25 miles north-east of Berlin.
- NIESTER**, a river which rises in Poland, and running south-east divides Podolia in Poland from Moldavia in Turkey; and afterwards, dividing Bessarabia from Budziaz Tartary, falls into the Black Sea near Belgorod.
- NIGELLA**, in botany, a genus of the polyandria pentagynia class. The calix is wanting; the corolla consists of five petals; there are five trisid nectaria within the corolla; and there are five connected capules. The species are five, none of them natives of Britain.
- NIGER**, a great river of Africa, which runs from east to west through the middle of Negroland, and discharges itself into the Atlantic ocean by three channels, called Rio Grande, Gambia, and the river Senega. It is 200 miles between the northern and southern channels; and all the country between them is annually overflowed, as Egypt is by the Nile.
- NIGHT**, that part of the natural day during which the sun is underneath the horizon; or that space wherein it is dusky.
- Night was originally divided by the Hebrews, and other eastern nations, into three parts, or watchings. The Romans, and afterwards the Jews from them, divide the night into four parts, or watches, the first of which began at sunset and lasted till nine at night, according to our way of reckoning; the second lasted till midnight; the third till three in the morning; and the fourth ended at sunrise. The ancient Gauls and Germans divided their time, not by days, but by nights; and the people of Iceland, and the Arabs, do the same at this day. The like is also observed of our Saxon ancestors.
- NIGHT-MARE**, in medicine. See **MEDICINE**, p. 157.
- NIGHT WALKERS**. See **NOCTAMBULI**.
- NIGHTINGALE**, in ornithology. See **MOTACILLA**.
- NIGRITIA**. See **NEGROLAND**.
- NILE**, a great river in Egypt, having its source in Abyssinia, or the Upper Ethiopia, in 12° north lat. It generally runs from south to north through Abyssinia into Egypt, and then continues its course north in one stream till it comes below Cairo to the Delta, where it divides; one branch discharging itself into the Mediterranean at Damietta, and another a hundred miles to the westward of it at Rosetta. There are great rejoicings every year when the Nile rises to a certain height, their future harvest depending upon it. The just height of the inundation, according to Pliny, is sixteen cubits; when it rises but to twelve or thirteen, a famine is dreaded; and when it exceeds sixteen, there is also danger apprehended. The river begins usually to rise in May or June, and is conveyed by reservoirs, cisterns, and canals, to the fields and gardens as they want it.
- As to the Delta, it is all overflowed.

- NIMBUS**, in antiquity, a circle above a certain medals, or round the head of some emperors, answering to the circles of light, drawn around the images of saints.
- NIMEGUEN**, a city of the united Netherlands, situated on the river Waal, in the province of Guelderland, 52 miles south east of Amsterdam.
- NIMETULAHITES**, a kind of Turkish monks, so called from their founder Nimetulahî, famous for his doctrines and the austerity of his life.
- NIMPO**, a city and port town of China, in the province of Chekiang: E. long. 122° , N. lat. 30° .
- NINEVEH**, an ancient city of Assyria, was situated on the eastern banks of the river Tygris, opposite to the place where Moufful now stands.
- NINOVE**, a town of the Aultrian Netherlands, in the province of Flanders, situated on the river Dender, thirteen miles west of Brussels.
- NIO**, a small Turkish island in the Archipelago, situated north-west of Santorini, remarkable for little but the tomb of Homer, who is said to lie buried here.
- NIORT**, a town of France, in the province of Orleans and territory of Poitou, situated on the river Seure, twenty eight miles north-east of Rochelle.
- NIPHON**, the largest of the Japan islands, situated in the Indian ocean about 130 miles east of China; being 600 miles long, and 150 broad, and containing 55 provinces.
- NIPPERS**, in the menage, are four teeth in the fore-part of a horse's mouth, two in the upper and two in the lower jaw. A horse puts them forth between the second and third year.
- NIPPLES**, in anatomy. See **ANATOMY**, p. 277.
- NIPPLE WORT**, in botany. See **LAPSAÑA**.
- NISI PRIUS**, in law, a judicial writ which lies in cases where the jury being impanelled and returned before the justices of the bank, one of the parties requests to have such a writ, for the sake of the country, in order that the trial may come before the justices in the same county on their coming thither. The purport of a writ of nisi prius is, that the sheriff is thereby commanded to bring to Westminster the men impanelled, at a certain day, before the justices, "nisi prius iusticiarii domini regis ad assisas capiendas venerint."
- NISMES**, a fine city of France, in the province of Languedoc: E. long. $4^{\circ} 26'$, N. lat. $43^{\circ} 40'$.
- NISNA**, or **NISS-NOVOGOROD**, the capital of the province of Nisse, or Little Novogorod, in Russia: E. long. 45° , N. lat. 56° .
- NISSA**, a city of European Turkey, in the province of Servia: E. long. 23° , N. lat. 43° .
- NISSA** or **NIZZA**, a town of Italy, in the duchy of Monterrat: E. long. $8^{\circ} 40'$, N. lat. $44^{\circ} 45'$.
- NITHSDALE**, a county of Scotland, bounded by Clydesdale on the north, by Annandale on the east, by Solway frith on the south, and by Galloway on the west.
- NITRACHT**, or **NYTREA**, a town of Hungary, forty miles north-east of Presburg.
- NITRE**, or **SALT-PETRE**. See **CHEMISTRY**, p. 73.

NIUCHE, a kingdom of Chinese Tartary, north of the province of Laotung.

NIVELLE, a town of the Austrian Netherlands, and province of Brabant, fourteen miles south of Brussels.

NIXABOUR, or **NISABOUR**, a city of Persia, in the province of Chorassan: E. long. $57^{\circ} 32'$, N. lat. $35^{\circ} 40'$.

NOBILIARY, in literary history, a book containing the history of the noble families of a nation, or province: such are Chorier's Nobiliary of Dauphine, and Caumartin's Nobiliary of Provence. The Germans are said to be particularly careful of their nobiliaries, in order to keep up the purity of their families.

NOBILITY, a quality that ennobles, and raises a person possessed of it above the rank of a commoner.

The origin of nobility in Europe is by some referred to the Goths; who, after they had seized a part of Europe, rewarded their captains with titles of honour, to distinguish them from the common people. In Britain the term nobility is restrained to degrees of dignity above knighthood; but every where else nobility and gentility are the same. The British nobility consists only of five degrees, *viz.* that of a duke, marquis, earl or count, viscount, and baron, each of which see under their proper articles.

NOBLE, a money of account containing six shillings and eight-pence.

The noble was anciently a real coin struck in the reign of Edward III. and then called the penny of gold; but it was afterwards called a rose-noble, from its being stamped with a rose: it was current at 6s. 8d.

NOCERA, a town of Italy, in the territory of the pope and duchy of Spoleto, twenty miles north-east of Spoleto.

Terra NOCERIANA, **EARTH OF NOCERA**, in the materia medica, a species of bole, remarkably heavy, of a greyish-white colour, of an insipid taste, and generally with some particles in it which grit between the teeth.

It is much esteemed, by the Italians, as a remedy for venomous bites, and in fevers; but, except its astringent quality, little dependence is to be had on the other virtues ascribed to it.

NOCTAMBULI, or **NIGHTWALKERS**, in medicine, a term applied to persons who have a habit of rising and walking about in their sleep.

NOCTILUCA, a species of phosphorus, so called because it shines in the night without any light being thrown upon it; such is the phosphorus made of urine. See **CHEMISTRY**, p. 123.

NOCTURNAL, something relating to the night, in contradistinction to diurnal.

NOCTURNAL, **NOCTURNALIUM**, an instrument chiefly used at sea, to take the altitude or depression of some stars about the pole, in order to find the latitude and hour of the night.

Some nocturnals are hemispheres, or planispheres, on the plane of the equinoctial. Those commonly in use among seamen are two; the one adapted to the polar star, and the first of the guards of the little bear; the other to the pole-star, and the pointers of the great bear.

This instrument consists of two circular plates, (Plate CXXXIV. fig. 2.) applied to each other. The greater, which has a handle to hold the instrument, is about $2\frac{1}{2}$ inches diameter, and is divided into twelve parts, agreeing to the twelve months; and each month sub-divided into every fifth day; and so as that the middle of the handle corresponds to that day of the year wherein the star here regarded has the same right ascension with the sun. If the instrument be fitted for two stars, the handle is made moveable. The upper left circle is divided into twenty four equal parts for the twenty four hours of the day, and each hour sub-divided into quarters. These twenty four hours are noted by twenty four teeth to be told in the night. Those at the hours 12, are distinguished by their length. In the centre of the two circular plates is adjusted a long index, A, moveable upon the upper plate. And the three pieces, *viz.* the two circles and index, are joined by a rivet which is pierced through the centre with a hole, through which the star is to be observed.

To use the **NOCTURNAL**, turn the upper plate till the long tooth, marked 12, be against the day of the month on the under plate: then, bringing the instrument near the eye, suspend it by the handle with the plane nearly parallel to the equinoctial; and viewing the pole-star through the hole of the centre, turn the index about, till, by the edge coming from the centre, you see the bright star or guard of the little bear (if the instrument be fitted to that star:) then that tooth of the upper circle, under the edge of the index, is at the hour of the night on the edge of the hour circle: which may be known without a light, by counting the teeth from the longest, which is for the hour 12.

NODATED HYPERBOLA, a name given by Sir Isaac Newton, to a kind of hyperbola, which, by turning round, decussates or crosses itself.

NODE, a tumour arising on the bones, and usually proceeding from some venereal cause; being much the same with what is otherwise called exostosis.

NODES. See **ASTRONOMY**, p. 477.

NODUS, or **NODE**, in dialling, a certain point or pole in the gnomon of a dial, by the shadow or light whereof either the hour of the day in dials without furniture, or the parallels of the sun's declination, and his place in the ecliptic, &c. in dials with furniture, are shewn. See **DIALLING**.

NOETIANS, in church history, Christian heretics in the III^d century, followers of Noetius, a philosopher of Ephesus, who pretended that he was another Moses, sent by God; and that his brother was a new Aaron. His heresy consisted in affirming that there was but one person in the Godhead; and that the Word and the Holy Spirit were but external denominations, given to God, in consequence of different operations; that as Creator, he is called Father; as Incarnate, Son; and as defending on the apostles, Holy Ghost.

NOGAIAN TARTARS, a nation which inhabits that part of Circassia, in Asiatic Turkey, that lies between the Palus Meotis and the Caspian sea.

NOGENT, a town of France, in the province of Champagne, situated on the river Seine, twenty five miles north-west of Troyes.

NOLA,

NOLA, a town of Italy, in the kingdom of Naples, situated 16 miles east of Naples.

NOLI, a town of Italy in the territory of Genoa, situated on the bay of Genoa, thirty five miles south west of that city.

NOMARCHA, in Egyptian antiquity, the governor or commander of a nome. Egypt was anciently divided into several regions or quarters, called nomes.

NOMBRE DE DIOS, a town of Mexico, in the province of Darien, a little to the eastward of Porto Bello: W. long. 83° and N. lat. 10°.

NOMBRIL POINT, in heraldry, is the next below the fess point, or the very centre of the escutcheon. See **POINT**.

Supposing the escutcheon divided into two equal parts below the fess, the first of these divisions is the nombril, and the lower the base.

NOME, or **NAME**, in algebra, denotes any quantity with a sign prefixed or added to it, whereby it is connected with some other quantity, upon which the whole becomes a binomial, trinomial, or the like. See **ALGEBRA**.

NOMENCLATOR, in Roman antiquity, was usually a slave, who attended upon persons that stood candidates for offices, and prompted or suggested to them the names of all the citizens they met, that they might court them, and call them by their names; which, among that people, was the highest piece of civility.

NOMENCLATOIRES, among the botanical authors, are those who have employed their labours about settling and adjusting the right names, fynonyms, and etymologies of names, in regard to the whole vegetable world.

NOMENCLATURE, a catalogue of several of the more usual words in any language, with their significations, compiled in order to facilitate the use of such words to those who are to learn the tongue: such are our Latin, Greek, French, &c. nomenclatures.

NOMINALS, **NOMINALISTS**, a sect of school philosophers, the disciples and followers of Occam, or Ockham, an English cordelier, in the XIVth century. They were great dealers in words, whence they were vulgarly denominated word-fellers; but had the denomination of nominalists, because that, in opposition to the realists, they maintained that words, and not things, were the object of dialectics.

NOMINATIVE, in grammar, the first case of nouns which are declinable. See **GRAMMAR**.

NONAGE, in law, generally signifies all the time a person continues under the age of one and twenty; but in a special sense, it is all the time a person is under the age of fourteen.

NON-CAPE, in geography, a promontory on the west coast of Africa, opposite to the Canary islands.

NON-ENTRY, in Scots law. See **LAW**, Tit. xii. 5.

NON-NATURALS, in medicine, so called because by their abuse they become the causes of diseases.

Physicians have divided the non-naturals into six classes, viz. the air, meats and drinks, sleep and watching, motion and rest, the passions of the mind, the retentions and excretions.

NON-SUIT, signifies the dropping of a suit or action, or a renouncing thereof by the plaintiff or defendant.

NONCONFORMISTS. See **DISSENTERS**.

NONE, one of the seven canonical hours in the Romish church, answering to three o'clock in the afternoon.

NONES, in the Roman kalendar, the fifth day of the months January, February, April, June, August, September, November, and December; and the seventh of March, May, July, and October. March, May, July, and October, had six days in their nones; because these alone, in the ancient constitution of the year by Numa, had thirty-one days a-piece, the rest having only twenty-nine, and February thirty: but when Cæsar reformed the year, and made other months contain thirty one days, he did not allot them six days of nones. See **KALENDAR**.

NORDEN, a port-town of Germany, in the circle of Westphalia, and county of Embden, twelve miles north of Embden.

NORFOLK, a county of England, bounded by the German sea on the north and east; by Suffolk on the south, and by the fens of Lincolnshire and the isle of Ely on the west.

NORFOLK, a county of Virginia, north of Carolina, and contiguous to that province.

NORMANDY, a province of France, bounded by the east channel on the north, by Picardy and the isle of France on the west, by Orleans on the south, by Britany and another part of the east channel on the west.

NORROY, the title of the third of the three kings at arms.

NORTH, one of the four cardinal points. See **NAVIGATION**.

NORTH CURRY, a market-town of Somersetshire, seventeen miles south-west of Wells.

NORTH FORELAND, a cape in the isle of Thanet, on the east coast of Kent, four miles east of Margate.

NORTH SEA, a name given to all that part of the Atlantic Ocean which lies north of Terra Firma, in South America.

NORTH-WEST passage. A north-west passage by Hudson's Bay, into the pacific ocean, has been more than once attempted of late years, but hitherto without success. Some greatly doubt of the practicableness of such an enterprize, and think the observations made by the Russians give us small hopes. Some general things may be seen in the Phil. Trans. N° 482. sect. 14. It appears from thence, that the Russians have passed between the land of Nova Zembla, and the coast of Asia; and, as the Dutch did formerly discover the northern coasts of Nova Zembla, we may now be well assured that that country is really an island.

NORTHALLERTON, a borough-town of the north riding of Yorkshire, twenty-two miles north-west of York. It sends two members to parliament.

NORTHAMPTON, the capital of Northamptonshire, situated on the river Nen: W. long. 55°, and N. lat. 52° 15'. It sends two members to parliament.

NORTHAMPTON, is also a county of Virginia, in North America,

- America, which forms the south part of the peninsula on the eastern shore of Virginia.
- NORTHHAUSEN**, a town of Germany in the circle of Upper Saxony, and territory of Thuringia, fifty-five miles south-west of Magdeburg.
- NORTHLEECH**, a market town of Gloucestershire, fifteen miles east of Gloucester.
- NORTHUMBERLAND**, a county of England, bounded on the north by Scotland, on the east by the German sea, on the south by Durham, and on the west by Cumberland and part of Scotland.
- NORTHUMBERLAND** is also a county of Virginia, lying at the mouth of the river Patowmac.
- NORTHWICH**, a market town of Cheshire, sixteen miles north-east of Chester.
- NORWAY**, a kingdom of Europe, situated between 4° and 30° east longitude, and between 58° and 72° north latitude, bounded by the Atlantic ocean on the north and west, by Swedish Lapland and other provinces of Sweden on the east, and by the sea called the Cate-gate and Schaggeric on the south. It is a cold barren country, subject to Denmark.
- NORWAY-RAT**, in zoology. See **MUS**.
- NORWICH**, a large city of great trade in Norfolk, situated 25 miles west of Yarmouth and the German ocean: E. long. $1^{\circ} 26'$, and N. lat. $52^{\circ} 40'$. It sends two members to parliament.
- NOSE**, in anatomy. See **ANATOMY**, p. 161, 162, 163, 231.
- NOTARY**, signifies a person, usually some scrivener, who takes notes, or frames short draughts, of contracts, obligations, charter-parties, or other writings. At present we call him a notary-public who publicly attests deeds, or writings, in order to make them authentic in another nation: but he is principally employed in business concerning merchants, as making protests of bills of exchange &c. And noting a bill, is where he goes to take notice of a merchant's refusal to accept or pay the same.
- NOTATION**, in arithmetic. See **ARITHMETIC**, p. 366.
- NOTES**, in music, characters which mark the sounds, *i. e.* the elevations and fallings of the voice, and the swiftness and slowness of its motions. See **MUSICK**.
- NOTE** is likewise used for a mark made in a book or writing where there occurs something remarkable and worthy of particular notice: as also for an observation or explication of some passage in an author added in the margin, at the bottom of the page, or elsewhere, in which sense it stands contradistinguished to text.
- NOTE**, is also a minute, or short writing, containing some article of business, in which sense we say, promissory note, note of hand, bank note, &c.
- NOŒUS**, signifies spurious or bastard; whence it is figuratively applied by physicians, &c. to such diseases as though in respect of a similitude of symptoms, &c. they have the same denomination as some others, yet are of a different origin, seat, or the like, from the same.
- NOTION**, in logic, an idea or representation of any thing in the mind. See **LOGIC** and **METAPHYSICS**.
- NOTITIA**, in literary history, a book that gives an account of a particular country, city, or other place: such is the *Notitia Imperii Romani*, *Notitia Romæ Antiquæ*, &c.
- NOTO**, the capital of a province of the same name in Sicily, twenty miles south of Syracuse; E. long. 15° , N. lat. $37^{\circ} 15'$.
- NOTONECTA**, the **BOAT-FLY** a genus of insects belonging to the order hemiptera. The peak is inflected; the antennæ are shorter than the thorax; the four wings are plaited cross-ways; and the feet are hairy, and fitted for swimming. There are three species, distinguished by their colour.
- NOTTEBURG**, a city of Russia, situated on an island in the lake Lodoga, twenty five miles east of Peterfburg.
- NOTTINGHAM**, the capital of Nottinghamshire, situated about a mile north of the river Trent; W. long. $1^{\circ} 5'$, N. lat. 53° . It sends two members to parliament.
- NOVA-SCOTIA**. See **SCOTLAND**.
- NOVA ZEMBLA**, or Newland, called by the Dutch the island of Weygats, is situated in the frozen ocean, between 50° and 80° east longitude, and between 70° north latitude and the north pole: it is separated from the province of Samoida, in Russia, by the straits of Weygats.
- NOVARA**, the capital of the Novarese, in the duchy of Milan, forty miles west of Milan.
- NOVATIANS**, a Christian sect which sprang up in the third century, so called from Novatian a priest of Rome, or Novatus an African bishop who separated from the communion of pope Cornelius, whom Novatian charged with a criminal lenity towards those who had apostatized during the persecution of Decius. He denied the church's power of remitting mortal sins, upon the offender's repentance; and at last went so far as to deny that the apostles could ever hope for pardon even from God himself.
- NOVATION**, or **INNOVATION**, in the civil law, denotes the change of one kind of obligation for another; as when a promise is accepted instead of a written obligation.
- NOVATION**, in Scots law. See **LAW**, Tit. xxiii. 7.
- NOVEL**, in matters of literature, a fictitious history of a series of entertaining events in common life, wherein the rules of probability are or ought to be strictly preserved.
- NOVELLARA**, a town of Italy, in the duchy of Mantua, twenty miles south of the city of Mantua.
- NOVEMBER**, in chronology, the eleventh month of the Julian year, consisting only of thirty days; it got the name of November, as being the ninth month of Romulus's year, which began with March.
- NOVEMVIRI**, the nine magistrates of Athens, more usually called archons.
- NOVIGRAD**, a town of Dalmatia, in $17^{\circ} 30'$ E. long. and $44^{\circ} 30'$ N. lat.
- NOUN**, in grammar, a part of speech, which signifies things without any relation to time; as a man, a house, sweet, bitter, &c. See **GRAMMAR**.
- NOVOGOROD**, the capital of a province of the same name in Muscovy, situated on the river Wolcoss, 120 miles

miles south east of Peterburg; E. long. 34°, N. lat. 59°.

It is an archbishop's see, and has 180 churches and monasteries.

NOVOGRODECK, a city of Lithuania, in Poland: E. long. 25° 30', N. lat. 53° 45'.

NOURISHMENT. See **NUTRITION**.

NOWED, in heraldry, signifies knotted, from the Latin *nodatus*; being applied to the tails of such creatures as are very long, and sometimes represented in coat-armour, as if tied up in a knot.

NUBIA, a country of Africa, bounded by the desert of Barca, on the north; by Egypt and Abyssinia, on the east; by the Lower Ethiopia, on the south; and by the deserts of Africa, on the west.

NUCHA, the nape of the neck.

NUCIFEROUS TREES, such as bear nuts.

NUCIFRAGA, in ornithology. See **CORVUS**.

NUCLEUS, in general denotes the kernel of a nut, or even any seed inclosed within a hulk.

The term nucleus is also used for the body of a comet, otherwise called its head. See **ASTRONOMY**, p. 444.

NUDITIES, in painting and sculpture, denotes those parts of an human figure which are not covered with any drapery; or those parts where the carnation appears.

NULLITY, in law signifies any thing that is null or void: thus there is a nullity of marriage, where persons marry within the degrees, or where infants marry without consent of their parents or guardians.

NUMBER. See **ARITHMETIC**.

Golden NUMBER. See **ASTRONOMY**, p. 495.

NUMBER, in grammar, a modification of nouns, verbs, &c. to accommodate them to the varieties in their objects, considered with regard to number. See **GRAMMAR**.

NUMBERS, in poetry. See **VERSIFICATION**.

Book of NUMBERS, the fourth book of the Pentateuch, taking its denomination from its numbering the families of Israel.

A great part of this book is historical, relating to several remarkable passages in the Israelites march through the wilderness. It contains a distinct relation of their several movements from one place to another, or the two and forty stages through the wilderness, and many other things, whereby we are instructed and confirmed in some of the weightiest truths that have immediate reference to God and his providence in the world. But the greatest part of this book is spent in enumerating these laws and ordinances, whether civil or ceremonial, which were given to God, but not mentioned before in the preceding books.

NOMENIUS, in ornithology, a genus of birds of the order of the scelopaces; the beak of which is of a figure approaching to a cylindrical one; it is obtuse at the point, and is longer than the toes; the feet have each 4 toes, connected together. This genus comprehends the curlew, the woodcock, the great plover, and the snipe. See **CURLEW**, &c.

NUMERAL LETTERS, those letters of the alphabet

which are generally used for figures; as I, one; V, five; X, ten; L, fifty; C, a hundred; D, five hundred; M, a thousand; &c.

NUMERATION, or **NOTATION**, in arithmetic. See **ARITHMETIC**, p. 366.

NUMERATOR of a fraction. See **ARITHMETIC**, p. 387.

NUMERICAL, **NUMEROUS**, or **NUMERAL**, something belonging to numbers; as numerical algebra is that which makes use of numbers, instead of letters of the alphabet. Also, numerical difference, is the difference whereby one individual is distinguished from another. Hence a thing is said to be numerically the same, when it is so in the strictest sense of the word.

NUMIDIA, in ornithology, a genus belonging to the order of gallinæ. On each side of the head there is a kind of coloured fleshy horn; and the beak is furnished with cere near the nostrils. There is but one species, a native of Africa.

NUMIDIA, the ancient name of Biledulgerid, in Africa.

NUMISMATOGRAPHIA, a term used for the description and knowledge of ancient medals and coins, whether of gold, silver, or brass.

NUMMUS, among the Romans, a piece of money otherwise called *sestertius*.

NUN, a woman, in several Christian countries, who devotes herself, in a cloister or nunnery, to a religious life.

There were women in the ancient Christian church who made public profession of virginity before the monastic life was known in the world, as appears from the writings of Cyprian and Tertullian. These, for distinction's sake, are sometimes called ecclesiastical virgins, and were commonly enrolled in the canon or matricula of the church. They differed from the monastic virgin chiefly in this, that they lived privately in their father's houses, whereas the others lived in communities: but their profession of virginity was not so strict as to make it criminal in them to marry afterwards if they thought fit. As to the consecration of virgins, it had some things peculiar in it; it was usually performed publicly in the church by the bishop. The virgin made a public profession of her resolution, and then the bishop put upon her the accustomed habit of sacred virgins. One part of this habit was a veil, called the *sacrum velamen*; another was a kind of mitre or coronet worn upon the head. At present, when a woman is to be made a nun, the habit, veil, and ring of the candidate are carried to the altar; and the herself, accompanied by her nearest relations, is conducted to the bishop, who, after mass and an anthem, the subject of which is, "that he ought to have her lamp lighted, because the bridegroom is coming to meet her," pronounces the benediction: then she rises up, and the bishop consecrates the new habit, sprinkling it with holy water. When the candidate has put on her religious habit, she presents herself before the bishop, and sings on her knees, *Ancilla Christi sum*, &c. then she receives the veil, and afterwards the ring, by which she is married to Christ; and lastly the crown of vir-

ginity. When she is crowned, an anathema is denounced against all who shall attempt to make her break her vows.

NUNCIO, or **NUNTIO**, an ambassador from the pope to some catholic prince or state; or a person who attends on the pope's behalf at a congress, or an assembly of several ambassadors.

NUNCUPATIVE, in the schools, something that is only nominal, or has no existence but in name.

NUNCUPATIVE TESTAMENT, in Scots law. See **LAW**, Tit. xxviii. 2.

NUNDINAL, **NUNDINALIS**, a name which the Romans gave to the eight first letters of the alphabet, used in their kalendar.

This series of letters, A, B, C, D, E, F, G, H, is placed and repeated successively from the first to the last day of the year: one of these always expressed the market days, or the assemblies called *nundinæ*, *quasi novendinæ*, because they returned every nine days. The country people, after working eight days successively, come to town the ninth, to sell their several commodities, and to inform themselves of what related to religion and government. Thus the nundinal day being under A on the first, ninth, seventeenth, and twenty fifth days of January, &c. the letter day will be the nundinal letter of the year following. These nundinals bear a very great resemblance to the dominical letters, which return every eight days, as the nundinals did every nine.

NUPTIAL RITES, the ceremonies attending the solemnization of marriage, which are different in different ages and countries.

NURENBURG, the capital of a territory of the same name, in the circle of Franconia, in Germany: E. long. 11°. N. lat. 49° 30'.

NURSERY, in gardening, is a piece of land set apart for raising and propagating all sorts of trees and plants, to supply the garden and other plantations. See **GARDENING**.

NUSANCE, in law, a thing done to the annoyance of another.

Nuances are either public or private. A public nuisance is an offence against the public in general, either by doing what tends to the annoyance of all the king's subjects, or by neglecting to do what the common good requires: in which case all annoyances and injuries to streets, high-ways, bridges, and large rivers, as also disorderly ale houses, bawdy-houses, gaming-houses, stages for rope-dancers, &c. are held to be common nuisances. A private nuisance is when only one person or family is annoyed, by the doing of any thing; as where a person stops up the light of another's house, or builds in such a manner that the rain falls from his house upon his neighbour's.

NUT, among botanists, denotes a pericarpium of an extraordinary hardness, inclosing a kernel or seed.

NUTATION, in astronomy, a kind of tremulous motion of the axis of the earth, whereby, in each annual revolution, it is twice inclined to the ecliptic, and as often returns to its former position.

NUTMEG, the kernel of a large fruit, not unlike the peach,

The nutmeg is separated from its investient coat, the mace, before it is sent over to us; except that the whole fruit is sometimes imported in preserve, by way of sweetmeat, or as a curiosity. See **MACE**.

The nutmeg, as we receive it, is of a roundish or oval figure, of a tolerably compact and firm texture, but easily cut with a knife, and falling to pieces on a smart blow. Its surface is not smooth, but furrowed with a number of wrinkles, running in various directions, though principally longitudinally. It is of a greyish brown colour on the outside, and of a beautiful variegated hue within, being marbled with brown and yellow variegations, running in perfect irregularity through its whole substance. It is very unctuous and fatty to the touch, when powdered; and is of an extremely agreeable smell, and of an aromatic taste.

There are two kinds of nutmeg in the shops, the one called by authors the male, and the other the female. The female is the kind in common use, and is of the shape of an olive: the male is long and cylindric, and has less of the fine aromatic flavour than the other; so that it is much less esteemed, and people who trade largely in nutmegs will seldom buy it. The longer male nutmeg, as we term it, is called by the Dutch the wild nutmeg. It is always distinguishable from the others, as well by its want of fragrancy, as by its shape: it is very subject to be worm-eaten, and is strictly forbid, by the Dutch, to be packed up among the other, because it will give occasion to their being worm-eaten too, by the insects getting from it into them, and breeding in all parts of the parcel.

The largest, heaviest, and most unctuous of the nutmegs are to be chosen, such as are of the shape of an olive, and of the most fragrant smell. The Dutch import them from the East-Indies.

Nutmeg is greatly used in our foods, and is of excellent virtues as a medicine; it is a good stomachic, it promotes digestion, and strengthens the stomach. It also stops vomiting; is an excellent remedy in flatulency; and is happily joined with rhubarb, and other medicines, in diarrhœas. It is observed to have a soporific virtue, and to exert it too strongly, if taken in moderate quantities. It has a considerable degree of altringency; and given, after toasting before the fire till thoroughly dry and crumbly, it has been sometimes known alone to cure diarrhœas.

NUTRITION, in the animal economy, is the repairing the continual loss, which the different parts of the body undergo. The motion of the parts of the body, the friction of these parts with each other, and especially the action of the air, would destroy the body entirely, if the loss was not repaired by a proper diet, containing nutritive juices; which being digested in the stomach, and afterwards converted into chyle, mix with the blood, and are distributed through the whole body for its nutrition.

In young persons, the nutritive juices not only serve to repair the parts that are damaged, but also to increase them, which is called growth.

In grown persons, the cuticle is every where constantly desquamating, and again renewing; and in the same manner the parts rubbed off, or otherwise separated

rated from the fleshy parts of the body, are soon supplied with new flesh; a wound heals, and an emaciated person grows plump and fat.

Buffon, in order to account for nutrition, supposes the body of an animal, or vegetable, to be a kind of mould, in which the matter necessary to its nutrition is modelled and assimilated to the whole. But, continues he, of what nature is this matter, which an animal, or vegetable, assimilates to its own substance? What power is it that communicates to this matter the activity and motion necessary to penetrate this mould? and, if such a force exist, would it not be by a similar force that the internal mould itself might be reproduced?

As to the first question, he supposes that there exists in nature an infinite number of living organical parts, and that all organized bodies consist of such organical parts; that their production costs nature nothing, since their existence is constant and invariable; so that the matter which the animal, or vegetable, assimilates to its substance, is an organical matter, of the same nature with that of the animal, or vegetable, which consequently may augment its volume, without changing its form, or altering the quality of the substance in the mould.

As to the second question: There exist, says he, in nature, certain powers, as that of gravity, that have no affinity with the external qualities of the body, but act upon the most intimate parts, and penetrate them throughout, and which can never fall under the observation of our senses.

And, as to the third question; he answers, that the internal mould itself is reproduced, not only by a similar power, but it is plain that it is the very same power that causes the unfolding and reproduction thereof: for it is sufficient, proceeds he, that in an organized body that unfolds itself, there be some part similar to the whole, in order that this part may one day become itself an organized body, altogether like that of which it is actually a part.

NUX PISTACHIA. See **PISTACHIA**.

NUYS, a town of Germany, twenty miles north of Cologne.

NYBURG, a town of Denmark, situated at the east-

end of the island of Funen, ten miles east of Odenfæ E. long. 10°, N. lat. 55° 30'.

NYCHTHEMERON, the natural day, or day and night, which together always make twenty-four hours.

NYCTALOPIA, in medicine, a two-fold disorder of the eye, one of which is opposite to the other. In the first, the sight is best in the night, and in obscure places; whereas in a clear light their sight fails, so that they can hardly see any thing. In the other sort of nyctylopiæ, the patient can see nothing at all except in a clear and bright light.

NYCTANTHES, *Arabian JASMINE*, in botany, a genus of the diandria monogynia class. The calix and likewise the corolla consist of eight segments. There are five species, none of them natives of Britain.

NYCTICORAX, in ornithology. See **ARDEA**.

NYLAND, a province of Finland, situated on the gulph of Finland, west of the province of Carelia.

NYMPH, in mythology, an appellation given to certain inferior goddesses inhabiting the mountains, woods, waters, &c. See **MYTHOLOGY**.

NYMPH, among naturalists, that state of winged insects between their living in the form of a worm, and their appearing in the winged or most perfect state.

NYMPHÆ, in anatomy. See **ANATOMY**, p. 276.

NYMPHÆA, the **WATER-LILY**, in botany, a genus of the polyandria monogynia class. The corolla consists of many petals, and the calix of four or five leaves; and the berry has many cells. There are four species, two of which are natives of Britain, viz. the lutea, or yellow water-lily; and the alba, or white water-lily.

NYMPHEUM, in antiquity, a public hall, magnificently decorated, for entertainment, &c. and where those who wanted convenience at home held their marriage-feasts, whence the name.

NYONS, a town of Dauphiné, in France: E. long. 5° 60', N. lat. 44° 28'.

NYSLOT, a town of Sweden in the province of Finland, sixty miles north of Wyburg: E. long. 29°, N. lat. 62°.

O.

O A K

AK, in botany. See **QUERCUS**.

OAK of Jerusalem, in botany. See **CHENOPODIUM**.

OAKAM, old ropes untwisted, and pulled out into loose hemp, in order to be used in caulking the seams, tree-nails, and bends of a ship, for stopping or preventing leaks.

OAKHAMPTON, a borough of Devonshire, twenty

miles west of Exter, which sends two members to parliament.

OAR, in navigation, a long piece of wood, made round where it is to be held in the hand, and thin and broad at the other end, for the easier cutting and resisting the water, and consequently moving the vessel, by rowing. Oars for ships are generally cut out of fir-timber; those for barges are made out of New-England, or Dantzick-

rafters; and those for boats either out of English ash, or fir-rafters from Norway.

OAT, in botany. See *AVENA*.

OATH, is a solemn affirmation, in which the persons sworn invoke the Almighty to witness that their testimony is true; renouncing all-claim to his mercy, and calling for his vengeance, if it be false.

OBADIAH, or the *Prophecy of OBADIAH*, a canonical book of the Old Testament, which is contained in one single chapter; and is partly an invective against the cruelty of the Edomites, who mocked and derided the children of Israel, as they passed into captivity, and with other enemies, their confederates, invaded and oppressed those strangers, and divided the spoil amongst themselves; and partly a prediction of the deliverance of Israel, and of the victory and triumph of the whole church over her enemies.

OBELISK, in architecture, a truncated, quadrangular, and slender pyramid, raised as an ornament, and frequently charged either with inscriptions or hieroglyphics.

Obelisks appear to be of very great antiquity, and to be first raised to transmit to posterity precepts of philosophy, which were cut in hieroglyphical characters: afterwards they were used to immortalize the great actions of heroes, and the memory of persons beloved. The first obelisk mentioned in history was that of Ramesses king of Egypt, in the time of the Trojan war, which was forty cubits high. Phisus, another king of Egypt, raised one of forty-five cubits; and Ptolemy Philadelphus, another of eighty-eight cubits, in memory of Arsinoe. Augustus erected one at Rome in the Campus Martius, which served to mark the hours on an horizontal dial, drawn on the pavement. They were called by the Egyptian priests the fingers of the sun, because they were made in Egypt also to serve as styles or gnomons to mark the hours on the ground. The Arabs still call them Pharaoh's needles; whence the Italians call them *aguglia*, and the French *aiguilles*.

OBERSSTEIN, the capital of the county of the same name, in the Palatinate of the Rhine, thirty miles east of Triers.

OBERSWESEL, or *WESEL*, a town of Germany, in the electorate of Triers, thirty-seven miles north east of the city of Triers.

OBJECT, in philosophy, something apprehended, or presented to the mind, by sensation or by imagination. See *METAPHYSICS*.

OBJECT-GLASS of a telescope. See *OPTICS*.

OBJECTION, something urged to overthrow a position, or a difficulty raised against an allegation or proposition of a person we are disputing withal.

OBJECTIVE is used, in the schools, in speaking of a thing which exists no otherwise than as an object known. The existence of such a thing is said to be objective.

OBLATI, in church history, were secular persons, who devoted themselves and their estates to some monastery, into which they were admitted as a kind of lay brothers. The form of their admission, was, putting the bell-

ropes of the church round their necks, as a mark of servitude. They wore a religious habit, but different from that of the monks.

OBLATION, a sacrifice, or offering made to God.

OBLIGATION, in Scots law. See *LAW Tit. XX*.

OBLIQUE, in geometry, something assant, or that deviates from the perpendicular. Thus an oblique angle is either an acute or obtuse one, *i. e.* any angle except a right one.

OBLIQUE CASES, in grammar, are all the cases except the nominative.

OBLIQUE LINE, that which falling on another line, makes oblique angles with it, *viz.* one acute, and the other obtuse.

OBLIQUE PLANES, in dialling, are those which recline from the zenith, or incline towards the horizon. See *DIALLING*.

OBLIQUE SAILING, in navigation. See *NAVIGATION*.

OBLIQUITY of the *ecliptic*. See *ASTRONOMY*.

OBLIQUUS, in anatomy, a name given to several muscles, particularly in the head, eyes, and abdomen.

See *ANATOMY*, Part II.

OBLONG, in general, denotes a figure that is longer than broad: such is a parallelogram, ellipsis, &c.

OBOLUS, in antiquity, an ancient Athenian coin.

Among ancient physicians, obolus likewise denoted a weight, equal to ten grains.

OBREPTITIOUS, an appellation given to letters patent, or other instruments, obtained of a superior by surprise, or by concealing from him the truth.

OBSCURE, something that is dark and reflects little light, or that is not clear and intelligible.

OBSECRATION, in rhetoric, a figure whereby the orator implores the assistance of God, or man.

OBSEQUIES, the same with funeral solemnities. See *FUNERAL*.

OBSERVATION, among navigators, signifies the taking the sun's or the star's meridian altitude, in order thereby to find the latitude.

OBSERVATORY, a place destined for observing the heavenly bodies; being generally a building erected on some eminence, covered with a terrace for making astronomical observations.

The more celebrated observatories are, 1. The Greenwich-observatory, built in 1676, by order of Charles II. at the solicitations of Sir Jonas Moore and Sir Christopher Wren; and furnished with the most accurate instruments, particularly a noble sextant of seven feet radius, with telescopic sights.

2. The parish-observatory, built by the late Louis XIV. in the Faubourg St. Jacques.

It is a very singular, but withal a very magnificent building; the design of monsieur Perault: It is eighty feet high; and at top is a terrace.

The difference in longitude between this and the Greenwich observatory is $2^{\circ} 20'$ west.

In it is a cave, or cellar, 170 feet descent, for experiments that are to be made far from the sun, &c. particularly such as relate to congelations, refrigerations, indurations, conservations, &c.

3. Tycho Brahe's observatory, which was in the little

little island Ween, or Scarlet island, between the coasts of Schonen and Zeland, in the Baltic.

It was erected and furnished with instruments at his own expence, and called by him Uraniburg.

Here he spent twenty years in observing the stars: the result is his catalogue.

4. Pekin observatory. Father Le Compte describes a very magnificent observatory, erected and furnished by the late emperor of China, in his capital, at the intercession of some Jesuits, missionaries, chiefly father Verbiest, whom he made his chief observer.

The instruments are exceedingly large; but the divisions less accurate, and the contrivance in some respects less commodious than those of the Europeans: the chief are, an armillary, zodiacal sphere, of six Paris feet diameter; an equinoctial sphere, of six feet diameter; an azimuthal horizon, six feet diameter; a large quadrant, six feet radius; a sextant, eight feet radius; and a celestial globe, six feet diameter.

OBSTRUCTION, in medicine, such an obstruction of the vessels, as prevents the circulation of the fluids, whether of the sound and vital, or of the morbid and peccant kind, through them.

OBTURATOR, in anatomy. See **ANATOMY**, p. 205.

OBTUSE, signifies blunt, dull, &c. in opposition to acute, sharp, &c. thus we say obtuse angle, obtuse-angled triangle, &c.

OBULARIA, in botany, a genus of the didymia angiospermia class. The calix has two segments; the corolla is campanulated, and divided into four segments; the capsule has one cell, two valves, and many seeds. There is but one species, a native of Virginia.

OBY, a great river of Russia, which rises in Kalmuck Tartary, and forms the boundary between Europe and Asia, till it falls into the frozen ocean, after it has run a course of above two thousand miles.

OCCIDENT, in geography, the westward quarter of the horizon, or that part of the horizon where the ecliptic, or the sun therein, descends into the lower hemisphere, in contradistinction to orient. Hence we use the word occidental, for any thing belonging to the west; as, occidental beard, occidental pearl, &c.

OCCIPITAL, in anatomy, a term applied to the parts of the occiput, or back part of the skull. See **ANATOMY**.

OCCIPITIS os, the **OCCIPITAL BONE**, in anatomy. See **ANATOMY**, p. 156.

OCCULT, something secret, hidden, or invisible. The occult sciences, are magic, necromancy, cabala, &c.

OCCULT, in geometry, is used for a line that is scarce perceivable, drawn with the point of the compasses, or a leaden pencil. These lines are used in several operations, as the raising of plans, designs of building, pieces of perspective, &c. They are to be effaced when the work is finished.

OCCULTATION, in astrology, the time a star or planet is hid from our sight, by the interposition of the body of the moon, or of some other planet. See **ASTRONOMY**.

OCCUPANT, in law, the person that first seizes, or gets possession of a thing.

OCCUPATION, in a legal sense, is taken for use or tenure; as in deeds it is frequently said, that such lands are or lately were in the tenure or occupation of such a person. It is likewise used for a trade or mystery.

OCCUPIERS of **WALLING**, a term in the salt-works for the persons who are the sworn officers that allot in particular places what quantity of salt is to be made, that the markets may not be overstocked, and see that all is carried fairly and equally between the lord and the tenant.

OCEAN, in geography, that vast collection of salt and navigable waters, in which the two continents, the first including Europe, Asia, and Africa, and the last America, are inclosed like islands.

OCHLOCRACY, that form of government wherein the populace has the chief administration of affairs.

OCHNA, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals, and the calix of five leaves; and the berry contains one seed. There are two species, both natives of the Indies.

OCHRE, in natural history, a genus of earths, slightly coherent, and composed of fine, smooth, soft, argillaceous particles, rough to the touch, and readily diffusible in water.

Ochres are of various colours, as red, yellow, blue, brown, green, &c.

OCYUM, in botany, a genus of the didymia gymnospermia class. The superior lip of the calix is round, and the inferior is divided into four segments. There are eight species, none of them natives of Britain.

OCKER, a river of Germany, which, rising in the southern part of the duchy of Brunswick, runs north; and passing by Wolfenbüttele and Brunswick, falls into the river Aller.

OCKINGHAM, a market-town of Berkshire, seven miles east of Reading.

OCTAETERIDES, in chronology, denotes a cycle of eight years, at the end of which three entire lunar months were added.

This cycle was in use at Athens, till Meton discovered the golden number.

OCTAGON, or **OCTOGON**, in geometry, is a figure of eight sides and angles; and this, when all the sides and angles are equal, is called a regular octagon, or one which may be inscribed in a circle.

OCTAGON, in fortification, denotes a place that has eight bastions. See **FORTIFICATION**.

OCTAHEDRON, or **OCTAEDRON**, in geometry, one of the five regular bodies, consisting of eight equal and equilateral triangles.

OCTANDRIA, in botany, one of the classes of plants established by Linnaeus, the eighth in order. See **BOTANY**.

OCTANT, or **OCTILE**, in astronomy, that aspect of two planets, wherein they are distant an eighth part of a circle, or 45° from each other.

OCTAPLA, in matters of sacred literature, denotes a polyglot bible, consisting of eight columns, and as many different versions of the sacred text; viz. the ori-

- ginal Hebrew both in Hebrew and Greek characters, Greek versions, &c.
- OCATEUCH**, an appellation given to the eight first books of the Old Testament.
- OCTAVE**, in music, an harmonical interval, consisting of seven degrees, or lesser intervals. See **MUSIC**.
- OCTOBER**, in chronology, the tenth month of the Julian year, consisting of thirty-one days : it obtained the name of October from its being the eighth month in the calendar of Romulus.
- ÖCTOSTYLE**, in the ancient architecture, is the face of an edifice adorned with eight columns.
- OCULUS**, the eye, in anatomy. See **ANATOMY**, p. 239.
- OCULUS BELII**, in natural history, one of the semi-pellucid gems, of a greyish white colour, variegated with yellow, and with a black central nucleus : it is of a roundish form, and its variegations very beautifully represent the pupil and iris of the eye ; whence the name.
- OCULUS MUNDI**, one of the semi-pellucid gems, of a whitish-grey colour, without any variegations.
- OCZAKOW**, a port town of European Turkey, the capital of Budziac Tartary : E. long. 35°, N. lat. 46°.
- ODA**, in the Turkish seraglio, signifies a class, order, or chamber. The grand seignior's pages are divided into five classes or chambers. The first, which is the lowest in dignity, is called the great oda, from the great number of persons that compose it : these are the juniors, who are taught to read, write, and speak the languages. The second, is called the little oda ; where from the age of fourteen or fifteen years, till about twenty, they are trained up to arms, and the study of all the polite learning the Turks are acquainted with. The third chamber, called kilar oda, consists of two hundred pages, which, besides their other exercises, are under the command of the kilarogji-bachi, and serve in the pantry and fruitery. The fourth consists only of twenty four, who are under the command of the khazineda bachi, and have charge of the treasure in the grand seignior's apartment, which they never enter with cloaths that have pockets. The fifth is called kas-oda, or privy-chamber, and is composed of only forty pages, who attend in the prince's chamber. Every night eight of these pages keep guard in the grand seignior's bed chamber, while he sleeps : they take care that the light, which is constantly kept in the room, does not glare in his eyes, lest it should awake him ; and if they find him disturbed with troublesome dreams, they cause him to be awaked by one of their agas.
- ODA BACHI**, or **ODDOBASSI**, among the Turks, an officer equivalent to a serjeant or corporal among us.
- ODE**, in poetry, a song, or a composition proper to be sung.
- Among the ancients, odes signified no more than songs ; but with us they are very different things. The ancient odes were generally composed in honour of their gods, as many of those of Pindar and Horace. These had originally but one stanza, or strophe ; but afterwards they were divided into three parts, the

strophe, the antistrophe, and the epode. The priests going round the altar singing the praises of the gods, called the first entrance, when they turned to the left, the strophe ; the second, turning to the right, they called antistrophe, or returning ; and, lastly, standing before the altar, they sung the remainder, which they called the epode.

Heroes and triumphs were also subjects for the ode ; and in course of time love and entertainments were likewise thought very suitable to it. Here Anacreon and Sappho excelled, and Horace has left us some of both sorts wrote with peculiar sweetness and elegance. Among the moderns, Dryden's ode on St Cecilia's day, and Pope's on the same subject, are justly allowed to exceed every thing of the kind, either in this, or in any of the modern languages.

ODENSEE, the capital of Funen, one of the largest of the Danish islands in the Baltic, situated seventy-two miles west of Copenhagen.

ODER, a river which rises in the Carpathian mountains, on the confines of Hungary ; runs through Silesia and Brandenburg ; and then separating the eastern from the western Pomerania, divides itself into several channels, and falls into the Baltic sea.

ODER is also a town of Silesia, situated on the river of the same name : E. long. 17° 17', N. lat. 49° 45'.

ODERBERG, a town in the duchy of Silesia, in Bohemia, situated on the river Oder : E. long. 17° 45', N. lat. 50° 6'.

ODERNHEIM, a town of Germany, in the palatinate of the Rhine, fifteen miles south of Menz.

ODEUM, in Grecian antiquity, a music-theatre, built by Pericles, the inside of which was filled with seats and ranges of pillars ; and on the outside the roof descended shelving downwards from a point in the centre, with many bendings, in imitation of the king of Persia's pavilion. Here the musical prizes were contended for ; and here also, according to Aristophanes, was a tribunal.

ODIHAM, a market-town of Hampshire, twenty miles north-east of Winchester.

ODONTALGIA, the **TOOTH ACH**, in medicine. See **MEDICINE**.

ODONTOIDE, in anatomy, an appellation given to a process of the second vertebra of the neck, from its resemblance to a tooth.

ODOROUS, or **ODORIFEROUS**, appellations given to whatever smells strongly, whether they be fetid or agreeable ; but chiefly to things whose smell is brisk, and agreeable.

ODYSSEY, a celebrated epic poem of Homer, wherein are related the adventures of Ulysses in his return from the siege of Troy.

OECONOMICS, the art of managing the affairs of a family, or community ; and hence the person who takes care of the revenues and other affairs of churches, monasteries, and the like, is termed oeconomus.

OECONOMY, denotes the prudent conduct, or discreet and frugal management, whether of a man's own estate, or that of another.

Animal OECONOMY, comprehends the various operations of

of nature, in the generation, nutrition, and preservation of animals. See GENERATION, NUTRITION, &c.

The doctrine of the animal oeconomy is nearly connected with physiology, which explains the several parts of the human body, their structure, use, &c. See ANATOMY.

OEUMENICAL, signifies the same with general, or universal; as oecumenical council, bishop, &c.

OEDEMA, in medicine and surgery. See MEDICINE and SURGERY.

OEDENBURG, or EDENBURG, a town of Hungary, thirty miles south of Vienna.

OELAND, a Swedish island in the Baltic sea, between the continent of Gothland, and the isle of Gothland: E. long. 16°, N. lat. between 56° and 57° 30'.

OELFELD, a town in the duchy of Magdeburg and circle of Lower Saxony in Germany, twenty miles east of Braunschweig.

OENANTHE, in botany, a genus of the pentandria digynia class. The flowers are sessile, dissimilar, and barren in the disk; and the fruit is crowned with a calix. There are five species, three of them natives of Britain, viz. the fistulosa, or water-dropwort; the pimpinelloides, or pimpinell-dropwort; and the crocata, or yellow dropwort.

OENANTHE, in ornithology, a species of motacilla. See MOTACILLA.

OENAS. See COLUMBA.

OENOPTÆ, in Grecian antiquity, a kind of censors at Athens, who regulated entertainments, and took care that none drank too much or too little.

OENOTHERA, in botany, a genus of the octandria monogynia class. The calix consists of four segments, and the corolla of four petals; the capsule is cylindrical, and the seeds are naked. There are seven species, none of them natives of Britain.

OESEL, an island at the entrance of the bay of Livonia, in the Baltic sea; situated in 22° of E. long. and 58° of N. lat.

OESOPHAGUS, in anatomy. See ANATOMY, p. 282.

OESTRUS, in zoology, a genus of insects belonging to the order of diptera. It has no mouth, but the point appears in place of it, without any proboscis or snout. There are five species, distinguished by their colour.

OETING, the capital of the county of the same name, in the circle of Swabia, in Germany: E. long. 10° 25', and N. lat. 49°.

OFFENBURG, a free-imperial city of the circle of Swabia, in Germany, situated on the river Kintzig: E. long. 7° 40', and N. lat. 48° 30'.

OFFENCE in law, an act committed against the law, or omitted where the law requires it.

OFFICE, a particular charge or trust, or a dignity attended with a public function. The word is primarily used in speaking of the offices of judicature and policy; as the office of a secretary of state, the office of a sheriff, of a justice of peace, &c.

OFFICE also signifies a place or apartment appointed for officers to attend in, in order to discharge their re-

spective duties and employments: as the secretary's office, office of ordnance, excise-office, signet-office, paper-office, pipe-office, fix-clerks office, &c.

OFFICE, in architecture, denotes all the apartments appointed for the necessary occasions of a palace or great house, as kitchens, pantries, confectionaries, &c.

OFFICE, in the canon-law, is used for a benefice that has no jurisdiction annexed to it.

OFFICER, a person possessed of a post or office. See the preceding article.

Commission-OFFICERS, are those appointed by the king's commission: such are all from the general to the cornet inclusive, who are thus denominated in contradistinction to warrant-officers, who are appointed by the colonel's or captain's warrant, as quarter-masters, serjeants, corporals, and even chaplains and surgeons.

Field OFFICERS are such as command a whole regiment, as the colonel, lieutenant-colonel, and major.

Flag OFFICERS. See FLAG-OFFICERS, and ADMIRAL.

General-OFFICERS are those whose command is not limited to a single company, troop, or regiment; but extends to a body of forces, composed of several regiments; such are the general, lieutenant-general, major-generals, and brigadiers.

OFFICERS of the household. See HOUSEHOLD.

Staff-OFFICERS are such as, in the king's presence, bear a white staff, or wand; and at other times, on their going abroad, have it carried before them by a footman bare-headed: such are the lord steward, lord chamberlain, lord treasurer, &c.

The white staff is taken for a commission, and at the king's death each of these officers breaks his staff over the hearth made for the king's body, and by this means lays down his commission, and discharges all his inferior officers.

Subaltern-OFFICERS are all who administer justice in the name of subjects; as those who act under the earl marshal, admiral, &c. In the army, the subaltern officers are the lieutenants, cornets, ensigns, serjeants, and corporals.

OFFICIAL, in the canon-law, an ecclesiastical judge, appointed by a bishop, chapter, abbot, &c. with charge of the spiritual jurisdiction of the diocese.

OFFICIAR, is also a deputy appointed by an archdeacon, as his assistant, who sits as judge in the archdeacon's court.

OFFICINAL, in pharmacy, an appellation given to such medicines, whether simple or compound, as are required to be constantly kept in the apothecaries shops.

OFFIDA, a town of Italy subject to the pope, twenty-six miles south of Loretto.

OFFING, or OFFIN, in the sea-language, that part of the sea a good distance from shore, where there is deep water, and no need of a pilot to conduct the ship: thus, if a ship from shore be seen sailing out to seaward, they say, she stands for the offing: and if a ship having the shore near her, have another a good way without her, or towards the sea, they say, that ship is in the offing.

OFF-SETS, in gardening, are the young shoots, that

spring from the roots of plants; which being carefully separated, and planted in a proper soil, serve to propagate the species.

OFF SETS, in surveying, are perpendiculars let fall, and measuring from the stationary lines to the hedge, fence, or extremity of an enclosure.

OGEE, or **O. G.** in architecture, a moulding consisting of two members, the one concave, and the other convex; or of a round and a hollow, like an S. See **ARCHITECTURE**.

OGIVE, in architecture, an arch, or branch of a gothic vault; which, instead of being circular, passes diagonally from one angle to another, and forms a cross with the other arches.

OGLIO, a river which rises in the alps, in the county of Trent, and, after running southward through the lake Iseo and duchy of Mantua, falls into the Po a little west of Borgoforte.

OHIO, a large river of North America, which, taking its rise in the mountains of Pennsylvania, runs south-west; and, after receiving many considerable branches, falls into the Mississippi.

OIL. See **CHEMISTRY**, p. 92. &c.

OINTMENT, in pharmacy. See **UNGUENT**.

OSIANS, a town of France, in the province of Dauphiné, eighteen miles south-east of Grenoble.

OSHAM, the capital of Rutlandshire, fourteen miles east of Leicester: W. long. 45°, and N. lat. 52° 40'.

OLAX, in botany, a genus of the triandria monogynia class. The corolla is entire; the calix is funnel-shaped, and divided into three segments; and the nectarium consists of four leaves. There is but one species, a native of Ceylon.

OLDENBURG, the capital of the county of the same name in Westphalia: E. long. 7° 32', and N. lat. 52° 35'.

OLDENDORP, a town of Germany in the circle of Westphalia, thirty miles south-west of Hanover.

OLDENLANDIA, a genus of the tetrandria monogynia class. The corolla consists of four leaves, and the calix of four segments; and the capsule has two cells, and many seeds. There are four species, none of them natives of Britain.

OLDENZEL, a city of the United Netherlands, in the province of Overijssel: E. long. 6° 50', and N. lat. 52° 30'.

OLD-WIFE FISH. See **BALISTES**.

OLEA, in botany, a genus of the diandria monogynia class. The corolla has four segments, with oval laciniæ; and the drupa contains one seed. There are two species.

This tree grows in the southern parts of France, in Spain, Italy, and other warm countries: with us it is usually preserved in the green-houses of the curious; though it will bear our ordinary winters in the open air, and produce very good fruit. Olives have an acrid, bitter, extremely disagreeable taste: pickled (as we receive them from abroad) they prove less disagreeable. The Lucca olives, which are smaller than the others, have the weakest taste; the Spanish, or larger,

the strongest; the Provence, which are of a middling size, are generally the most esteemed.

The oil obtained from this fruit has no particular taste or smell, and does not greatly differ in quality from oil of almonds. Authors make mention of two sorts of this oil, one expressed from the olives when fully ripe, which is our common oil olive; the other, before it has grown ripe; this is called *oleum immaturum*, and *emphacinum*. Nothing is met with in the shops under this name; and Lemery affirms, that there is no such oil, unripe olives yielding only a viscid juice to the press. From the ripe fruit, two or three sorts are obtained, differing in degree of purity; the purest runs by light pressure; the remaining magma, heated and pressed more strongly, yields an inferior sort, with some dregs at the bottom, called *amurca*. All these oils contain a considerable portion of aqueous moisture, and a mucilaginous substance; which subject them to run into a putrid state; to prevent this, the preparers add some sea salt, which imbibing the aqueous and mucilaginous parts, sinks with them to the bottom; by this means the oil becomes more homogeneous, and consequently less susceptible of alteration. In its passage to us, some of the salt, thrown up from the bottom by the shaking of the vessel, is sometimes mixed with and detained in the oil, which, in our colder climate, becomes too thick to suffer it freely to subside; and hence the oil is sometimes met with of a manifestly saline taste. Oil-olive is used in the simple balsam of sulphur, Locatellie's balsam, and several ointments. It is often employed in this last intention than the other expressed oils, but more rarely for internal medicinal purposes.

OLEAGINOUS, something that partakes of the nature of oil, or out of which oil may be expressed.

OLECRANUM, or **OLECRANON**, in anatomy. See **ANATOMY**, p. 178.

OLERON, an island of France, near the coast of Poitou, fourteen miles south-west of Rochelle, being about fifteen miles long, and six broad.

Sea-laws of **OLERON**, certain laws relating to maritime affairs, made in the time of Rich. I. when he was at the island Oleron.

These laws, being accounted the most excellent sea-laws in the world, are recorded in the black book of the admiralty.

OLESCO, a town of upper Volhynia, in Poland: east longitude 24°, and north latitude 50°.

OLFACTORY NERVES. See **ANATOMY**, p. 248.

OLIBANUM, **FRANK-INCENSE**, in pharmacy, a dry resinous substance, brought to us in detached pieces, or drops as it were, like those of mastic; but larger, and of a less pure and pellucid texture.

It is of a pale yellowish white colour, but with some mixture of a brownish cast in it. It is moderately heavy; its smell is strong, but not disagreeable; and its taste bitter, acrid, and resinous.

Olibanum is to be chosen whitish, pure, dry, and as much approaching to pellucidity as may be.

Olibanum is greatly commended by many against disorders of the head and breast, and against diarrheas and

and dysenteries, and profluvia of the menses, and the fluor albus. Its dose is from ten grains to a drachm. It is esteemed by many a specific in pleurisies, especially when epidemic.

Externally it is used in fumigations for disorders of the head, and against catarrhs; and is an ingredient in some plasters. It is a noble balsam in consumptions, given in substance, or dissolved with the yolk of an egg into the form of an emulsion. There is an oil made of it per deliquium, in the same manner as that of myrrh: this is done by putting the powder of it in the white of a boiled egg, in a cellar, till it runs into a liquor; this is esteemed a great cosmetic, and destroyer of pimples in the face.

OLIGAEDEIRA, in natural history, the name of a genus of crystals, and expresses that which is composed of only a few planes.

The bodies of this class are crystals of the imperfect kind, being composed of columns affixed irregularly to some solid body at one end, and the other terminated by a pyramid; but the column and pyramid being both pentangular, the whole consists only of ten planes, and not, as the common kind, of twelve.

OLIGARCHY, a form of government, wherein the administration of affairs is lodged in the hands of a few persons.

OLINDA, a city and port-town of Brasil: west long. 35°, and south lat. 8°.

OLIO, in cookery, denotes a savoury dish composed of a great variety of ingredients, chiefly used by the Spaniards.

OLIVA, a port-town of Poland, in the province of regal Prussia, only six miles west of Dantzick.

OLIVARIA CORPORA, in anatomy. See **ANATOMY**, p. 287.

OLIVE, in botany. See **OLEA**.

OLIVE-COLOUR, a yellow mingled with black. See **OPTICS**.

OLIVENZA, a town of Alentejo, in Portugal, ten miles south of Elvas.

OLMUTS, a city of Moravia, seventy-five miles north of Vienna.

OLYMPIA, a port-town of the Morea, at present called Longinico: east long. 21° 35', and north lat. 37° 40'.

OLYMPIAD, the space or period of four years, whereby the Greeks reckoned time. See **ASTRONOMY**, p. 493.

OLYMPIC GAMES were solemn games, famous among the ancient Greeks, so called from Olympian Jupiter, to whom they were dedicated; and by some said to be first instituted by Jupiter, after his victory over the sons of Titan; others ascribe their institution to Hercules, not the son of Alcmena, but one of much greater antiquity; others, to Pelops; and others, to Hercules the son of Alcmena. These games were so considerable, that the Greeks made them their epocha, distinguishing their years by the return of the olympics.

The care and management of these games belonged, for the most part, to the Eleans, who, on that account, enjoyed their possessions without molestation, or fear of

war or violence. They appointed a certain number of judges, who were to take care that those who offered themselves as competitors performed their preparatory exercises; and these judges, during the solemnity, sat naked, having before them a crown of victory, formed of wild-olive, which was presented to whomever they adjudged it. Those who were conquerors, were called Olympionices, and were loaded with honours by their countrymen. At these games women were not allowed to be present; and if any woman was found to have passed the river Alpheus, during the solemnity, she was to be thrown headlong from a rock.

OLYMPUS, the name of two mountains, the one in Bythonia in the Lesser Asia, and the other in the island of Cyprus.

OMAN, a province or kingdom in the south-east parts of Arabia Felix.

OMBRE, a celebrated game at cards, borrowed from the Spaniards, and played by two, by three, or by five persons, but generally by three.

OMBRE DE SOLEIL, **SHADOW OF THE SUN**, in heraldry, is when the sun is borne in armory, so as that the eyes, nose, and mouth, which at other times are represented, do not appear; and the colouring is thin, so that the field can appear through it.

OMBRIA, the ancient name of a province of Italy, in the territory of the pope, now called Spoleto and Perugia.

OMBRO, or **LOMBRO**, a town of Italy, in the duchy of Tuscany, and territory of the Siennois, situated near the Tuscan sea, a little south of the lake of Castiglione, forty-five miles south-west of Sienna.

OMELET, or **AMLET**, a kind of pancake or fricasse of eggs, with other ingredients, very usual in Spain and France.

OMEN, a certain accident and casual occurrence that was thought to preface either good or evil. There were three sorts of omens among the ancients. One was of things internal, or those which affected the persons themselves; the second, of things external, that only appeared to men, but did not make any impression on them; the third were ominous words. Of the first sort were those sudden convulsions, called panic fears, that seized upon men without any visible cause, and were therefore imputed to the demons, especially the god Pan: of these panics there is frequent mention in history. The second sort of omens were of such things as appeared to men, but were not contained in their own bodies. Of these there were several sorts: the beginning of things were thought to contain something ominous: it was thought a direful omen, when any thing unusual befel the temples, altars, or statues of the gods. Under the head of external omens are to be placed those which offered themselves in the way; such were the meeting of an eunuch, a black, a bitch with whelps, a snake lying in the road, &c. Words were ominous; and as they were good or bad, were believed to preface accordingly.

OMENTUM, in anatomy. See **ANATOMY**, p. 266.

OMERS,

OMERS, or St. OMERS, a city of Artois, in the French Netherlands, twenty miles south of Dunkirk, and eighteen south-east of Calais.

OMLANDS, a division of the province of Groningen, in the United Provinces.

OMMEN, a town of the United Netherlands, in the province of Overijssel, situated on the lesser Vecht, seventeen miles north-east of Deventer.

OMOPHAGIA, an ancient Greek festival, in honour of Bacchus, surnamed Omophagos, *i. e.* eater of raw flesh. This festival was observed in the same manner with the other festivals of Bacchus, in which they counterfeited madness; what was peculiar to it, was that the worshippers used to eat the entrails of goats, raw and bloody, in imitation of the god, who was supposed to do the same thing.

OMOPLATE, in anatomy. See ANATOMY, p. 176.

OMPHALO-MESENTERIC, in anatomy. All fœtuses are wrapped up in at least two coats or membranes; most of them have a third, called allantoides, or urinary.

Some, as the dog, cat, hare, &c. have a fourth, which has two blood-vessels, *viz.* a vein and an artery, called omphalo-mesenterics, because passing along the string to the navel, and terminating in the mesentery.

ONANDAGOE, one of the tribes of the Iroquois, or Five Nations, situated on the lake Ontario, or Frontenac, in North America: they are allies of Great Britain.

ONANIA, or ONANISM, terms which some late empirics have framed, to denote the crime of self-pollution, mentioned in scripture to have been practised by Onan, and punished in him with death.

ONEGA LAKE, a lake upwards of an hundred miles long, and forty broad, situated in the empire of Russia between 61° and 63° of north lat. and 35° east longitude.

ONEGLIA, a port town of Italy, seventy miles south-west of Genoa, subject to the king of Sardinia: E. long. 8° 30', and north lat. 44°.

ONEIROCRITICA, the art of interpreting dreams, or predicting future events from dreams.

ONGAR, a market town of Essex, ten miles west of Chelmsford.

ONGLE'E, in heraldry, an appellation given to the talons or claws of beasts or birds, when borne of a different colour from that of the body of the animal.

ONION. See CERA.

ONISCUS, in zoology, a genus of insects, belonging to the order of aptera. It has 14 feet, bristly feelers, and an oval body. There are 17 species.

ONKOTOMY, in surgery, the operation of opening a tumour or abscess. See SURGERY.

ONOCLEA, in botany, a genus of the cryptogamia filices class: the fruit consists of several globular capsules, with five valves and one cell, in which are several small hairy seeds.

ONOCROTALUS, in ornithology. See PELICANUS.

ONOMANCY, a branch of divination, which foretels

the good or bad fortune of a man, from the letters in his name.

From much the same principle the young Romans toasted their mistresses as often as there were letters in their names: hence Martial says,

Nevia sex cyathis, septem Jussina bibatur.

ONOMATOPOEIA, in grammar and rhetoric, a figure where words are formed to resemble the sound made by the things signified; as the buz of bees, the cackling of hens, &c.

ONONIS, in botany, a genus of the diadelphia decandria class. The calix has five segments; the vexillum is striated; and the pod is sessile and turgid. There are 19 species, three of them natives of Britain, *viz.* the spinosa, or reft-harrow; the arvensis, or corn reft-harrow; and the repens, or creeping reft-harrow.

ONOPORDUM, a genus of the syngenesia polygamia æqualis class. The receptacle is naked, and the scales of their calix are sharp-pointed. There are four species, none of them natives of Britain.

ONTARIO, or FRONTENAC, a lake of North America: situated in W. long. 79°, and between 41° and 43° N. lat.

ONTOLOGY. See METAPHYSICS.

ONYX, in natural history, one of the semipellucid gems, with variously coloured zones, but none red; being composed of crystal, defaced by a small admixture of earth; and made up either of a number of flat plates, or of a series of coats surrounding a central nucleus, and separated from each other by veins of a different colour, resembling zones or belts.

We have four species of this gem. 1. A bluish white one, with broad white zones. 2. A very pure onyx, with snow-white veins. 3. The japonix, or horny onyx, with green zones. 4. The brown onyx, with bluish white zones.

OOST, a kiln for drying hops after they are picked from the stalks.

OOSTERGO, the north division of West Friesland, one of the United Provinces.

OPACITY, in philosophy, a quality of bodies which renders them impervious to the rays of light. See OPTICS.

OPAL, in natural history, a species of gems.

The opal is a gem of a peculiar kind, and has been esteemed by many in all ages of very great value; though at present it is of less value, in proportion to its size, than any of the finer gems. It is softer than any other of the fine gems, and is difficult to polish to any degree of nicety. It is found of various shapes and sizes: its most frequent bigness is between that of a pea and a horse-bean; but it is found as small as the head of a large pin, and has been seen of the size of a large walnut. Its figure is very various and uncertain, but it is never found in a crystalliform or columnar state; its most usual shape is an irregularly oblong one, convex above, flattened at bottom, and dented with various sinuities at its sides. It is often found among the loose earth of mountains, sometimes on the shores of rivers, and not unfrequently bedded in the coarser kinds of jasper.

- It is found in Egypt, Arabia, some parts of the East-Indies, and in many parts of Europe : those of Europe are principally from Bohemia, and are of a greenish or greyish colour ; the colour of other opals much resembles the finest mother of pearl, its basis seeming a bluish or greyish white, but with a property of reflecting all the colours of the rainbow, as turned differently to the light.
- OPALIA**, in antiquity, feasts celebrated at Rome in honour of the goddesses, Ops. Varro says they were held on the nineteenth of December, which was one of the days of the Saturnalia : these two feasts were celebrated in the same month, because Saturn and Ops were husband and wife : the vows offered to the goddesses were made sitting on the ground.
- OPERA**, a dramatic composition set to music, and sung on the stage, accompanied with musical instruments, and enriched with magnificent dresses, machines, and other decorations.
- OPERATION**, in general, the act of exerting or exercising some power or faculty, upon which an effect follows.
- OPERATION**, in chirurgery, denotes a methodical action of the hand on the human body, in order to reestablish health. See **SURGERY**.
- OPERATOR**, a person who performs an operation.
- OPHIDIUM**, in ichthyology, a genus belonging to the order of apodes. The head is somewhat naked ; the teeth are in the jaws, palate, and fauces ; there are seven rays in the gill membrane ; and the body is shaped like a sword. There are two species, *viz.* the barbatus, with four cirri ; and the imberbe, which has no cirri, and the tail is blunt.
- OPHIOGLOSSUM**, in botany, a genus of the cryptogamia filices class. The spike is jointed. There are seven species, only one of which, *viz.* the vulgatum, or adders-tongue, is a native of Britain.
- OPHIOMANCY**, in antiquity, the art of making predictions from serpents. Thus Calchas, on seeing a serpent devour eight sparrows with their dam, foretold the duration of the siege of Troy. And the seven quails of a serpent that was seen on Anchises's tomb, were interpreted to mean the seven years that Æneas wandered from place to place before he arrived in Latium.
- OPHIORHIZA**, in botany, a genus of the pentandria monogynia class. The calix is funnel-shaped ; the germs are bifid ; it has two stigmata ; and the fruit has two lobes ; there are two species, none of them natives of Britain.
- OPHIOXYLON**, in botany, a genus of the polygamia monocia class. The corolla and calix of the hermaphrodite consists of five segments ; it has five stamina, and one pistillum : The calix of the male is bifid ; the corolla is funnel-shaped, with a cylindrical nectarium near the inner edge, and consists of five segments ; it has only two stamina. There is but one species, a native of Ceylon.
- OPHITES**, in natural history, a sort of variegated marble, of a dusky-green ground, sprinkled with spots of a lighter green, otherwise called serpentine.
- OPHITES**, in church history, Christian heretics, so called both from the veneration they had for the serpent that tempted Eve, and the worship they paid to a real serpent.
- OPHYRS**, in botany, a genus of the gynandria diandria class. The nectarium has a kind of carina on the under part. There are 18 species, eleven of which are natives of Britain.
- OPHTHALMIA**, in medicine, an inflammation of the membranes which invest the eye ; especially of the adnata, or albugineous coat. See **MEDICINE**.
- OPHTHALMIC NERVES**. See **ANATOMY**, p. 248.
- OPHTHALMOSCOPY**, a branch of physiognomy, which deduces the knowledge of a man's temper and manners from the appearance of his eyes.
- OPIATES**, medicines of a thicker consistence than a syrup, prepared with opium scarcely fluid. They consist of various ingredients, made up with honey or syrup ; and are to be used for a long time either for purgative, alterative, or corroborative intentions.
- The word opiate is also used, in general, for any medicine given with an intention to procure sleep, whether in the form of electuaries, drops, or pills.
- OPINION**, is defined to be an assent of the mind to propositions not evidently true at first sight.
- OPISTHOTONOS**, in medicine, a kind of convulsion, wherein the body is bent backwards.
- OPIUM**, in the materia medica, is an inspissated juice, partly of the resinous, and partly of the gummy kind, brought to us in cakes from eight ounces to a pound weight. It is very heavy, of a dense texture, and not perfectly dry ; but, in general, easily receives an impression from the finger : its colour is a brownish yellow, so very dark and dusky that at first it appears black : it has a dead and faint smell, and its taste is very bitter and acrid. It is to be chosen moderately firm, and not too soft ; its smell and taste should be very strong, and care is to be taken that there is no dirty or stony matter in it.
- Opium is the juice of the papaver album, or white poppy, with which the fields of Asia Minor are in many places sown, as ours are with corn. When the heads are near ripening, they wound them with an instrument that has five edges, which on being stuck into the head makes at once five long cuts in it ; and from these wounds the opium flows, and is next day taken off by a person who goes round the field, and put up in a vessel which he carries fastened to his girdle ; at the same time that this opium is collected, the opposite side of the poppy head is wounded, and the opium collected from it the next day. They distinguish, however, the produce of the first wounds from that of the succeeding ones ; for the first juice afforded by the plant is greatly superior to what is obtained afterwards. After they have collected the opium, they moisten it with a small quantity of water or honey, and work it a long time upon a flat, hard, and smooth board, with a thick and strong instrument of the same wood, till it becomes of the consistence of pitch ; and then work it up with their hands, and form it into cakes or rolls for sale.

Opium at present is in great esteem, and is one of the most valuable of all the simple medicines. Applied externally, it is emollient, relaxing, and discutient, and greatly promotes suppuration: if long kept, upon the skin, it takes off the hair, and always occasions an itching in it; sometimes it exulcerates it, and raises little blisters, if applied to a tender part: sometimes, on external application, it allays pain, and even occasions sleep: but it must by no means be applied to the head, especially to the sutures of the skull; for it has been known to have the most terrible effects in this application, and even to bring on death itself. Opium, taken internally removes melancholy, eases pain, and disposes to sleep; in many cases removes hæmorrhages, provokes sweating. A moderate dose is commonly under a grain; though, according to the circumstances, two grains, or even three, may be within the limits of this denomination: but custom will make people bear a dram or more; though in this case nature is vitiated, and nothing is to be hence judged in regard to others. If given dissolved, it operates in half an hour; if in a solid form, as in pills, or the like, it is sometimes an hour and a half. Its first effect, in this case, is the making the patient cheerful, as if he had drank moderately of wine, and at the same time bold and above the fear of danger; for which reason the Turks always take it when they are going to battle. A very immoderate dose brings on a sort of drunkenness, much like that occasioned by an immoderate quantity of strong liquors; cheerfulness and loud laughter at first, than a relaxation of the limbs, a loss of memory, and lightheadedness; then vertiges, dimness of the eyes, with a laxity of the cornea and a dilatation of the pupils, a slowness of the pulse, redness of the face, relaxation of the under jaws, swelling of the lips, difficulty of breathing, painful erection of the penis, convulsions, cold sweats, and finally death. Those who escape are usually relieved by a great number of stools, or profuse sweats.

Prepared opium, commonly called extract of opium, is made by dissolving opium in a sufficient quantity of water with a gentle heat; then straining the solution from the fæces, and evaporating it to the consistence

of honey. Tincture of opium, or liquid laudanum, otherwise called the thebaic tincture, is made as follows: Take of prepared opium, two ounces; of cinnamon and cloves, each one drachm; of white-wine, one pint; infuse them a week without heat, and then filter it through paper.

OPOBALSAMUM, in the materia medica. See BAL-SAM.

OPOPANAX, in the materia medica, is a gum resin of a tolerably firm texture, usually brought to us in loose granules or drops, and sometimes in large masses, formed of a number of these connected by a quantity of matter of the same kind; but these are usually loaded with extraneous matter, and are greatly inferior to the pure loose kind. The drops or granules of the fine opopanax, are on the outside of a brownish red colour, and of a dusky yellowish or whitish colour within: they are of a somewhat unctuous appearance, smooth on the surface; and are to be chosen in clear pieces, of a strong smell and acrid taste.

Opopanax is attenuating and discutient, and is gently purgative; it dispels flatulencies, and is good in asthma, in inveterate coughs, and in disorders of the hand and nerves. It also promotes the menses, and is good against all obstructions of the viscera.

OPOSSUM, in zoology. See DIDELPHIS.

OPPIATION, in medicine, the act of obstructing or stopping up the passages of the body, by redundant or peccant humours. This word is chiefly used for obstructions in the lower belly.

OPPONENT, a person who withstands or opposes another.

OPPOSITION, in logic, the disagreement between propositions which have the same subject and the same predicate.

OPTATIVE mood, in grammar, that which serves to express an ardent desire or wish for something.

In most languages, except the Greek, the optative is only expressed by prefixing to the subjunctive an adverb of wishing; as *utinam*, in Latin; *plut a Dieu*, in French; and *would to God*, in English.

OPTERIA, in antiquity, presents made by a bridegroom to his bride, when first conducted to him.

O P T I C S.

THE cause and nature of vision are properly the subject of that part of natural philosophy which is called Optics: but as light is the cause of vision, the word Optics is commonly used in a more extensive sense; and every thing is looked upon as a part of Optics which relates to the nature and qualities of light. If we use the word Optics, in the stricter sense of it, for the theory of vision, the science of Optics is divided into two parts, viz. Dioptrics and Catoptrics. The laws of refraction, and the effects which the refraction of light has in vision, are the subject of Dioptrics: The laws of reflection, and the effects which the reflection of light has in vision, are the

subject of Catoptrics. But this division of Optics is of no use; for there are many propositions in Optics where both parts are mixed, and many that cannot be properly reduced to either; and therefore we shall not make any use of that distinction in the following Treatise.

Of Light.

LIGHT consists of an inconceivably great number of particles flowing from a luminous body in all manner of directions; and these particles are so small, as to surpass all human comprehension.

That the number of particles of light is inconceivably great

great, appears from the light of a candle; which, if there be no obstacle in the way to obstruct the passages of its rays, will fill all the space within two miles of the candle every way with luminous particles, before it has lost the least sensible part of its substance.

A ray of light is a continued stream of these particles, flowing from any visible body in a straight line: and that the particles themselves are incomprehensibly small, is manifest from the following experiment. Make a small pin-hole in a piece of black paper, and hold the paper upright on a table facing a row of candles standing by one another; then place a sheet of pasteboard at a little distance behind the paper, and some of the rays which flow from all the candles through the hole in the paper, will form as many specks of light on the pasteboard, as there are candles on the table before the plate: each speck being as distinct and clear, as if there was only one speck from one single candle: which shews, that the particles of light are exceedingly small, otherwise they could not pass through the hole from so many different candles without confusion—Dr Niewentyt has computed, that there flows more than 6,000,000,000,000 times as many particles of light from a candle in one second of time, as there are grains of sand in the whole earth, supposing each cubic inch of it to contain 1,000,000.

These particles, by falling directly upon our eyes, excite in our minds the idea of light. And when they fall upon bodies, and are thereby reflected to our eyes, they excite in us the ideas of these bodies. And as every point of a visible body reflects the rays of light in all manner of directions, every point will be visible in every part to which the light is reflected from it. Thus the object *ABC* (OPTICAL PLATES, fig.ⁿ 1.) is visible to an eye in any part where the rays *Aa, Ab, Ac, Ad, Ae, Ba, Bb, Bc, Bd, Be,* and *Ca, Cb, Cc, Cd, Ce,* come. Here we have shewn the rays as if they were only reflected from the ends *A* and *B*, and from the middle point *C* of the object; every other point being supposed to reflect rays in the same manner. So that, where-ever a spectator is placed with regard to the body, every point of that part of the surface which is towards him will be visible, when no intervening object stops the passage of the light.

Since no object can be seen through the bore of a bent pipe, it is evident that the rays of light move in straight lines, whilst there is nothing to refract or turn them out of their rectilinear course.

Whilst the rays of light continue in any * medium of an uniform density, they are straight; but when they pass obliquely out of one medium into another which is either more dense or more rare, they are refracted towards the denser medium: and this refraction is more or less, as the rays fall more or less obliquely on the refracting surface which divides the mediums.

To prove this by experiment, set the empty vessel *ABCD* (No. 2.) into any place where the sun shines obliquely, and observe the part where the shadow of the edge *BC* falls on the bottom of the vessel at *E*; then fill the vessel with water, and the shadow will reach no farther than *e*; which shews, that the ray *aBE*, which came

straight in the open air, just over the edge of the vessel at *B* to its bottom at *E*, is refracted by falling obliquely on the surface of the water at *B*; and instead of going on in the rectilinear direction *aBE*, it is bent downward in the water from *B* to *e*, the whole bend being at the surface of the water: and so of all other rays *abc*.

If a stick be laid over the vessel, and the sun's rays be reflected from a glass perpendicularly into the vessel, the shadow of the stick will fall upon the same part of the bottom, whether the vessel be empty or full: which shews that the rays of light are not refracted when they fall perpendicularly on the surface of any medium.

The rays of light are as much refracted by passing out of water into air, as by passing out of air into water. Thus, if a ray of light flows from the point *e*, under water, in the direction *eB*; when it comes to the surface of the water at *B*, it will not go on thence in the rectilinear course *Bd*, but will be refracted into the line *Ba*. Therefore,

To an eye at *e* looking through a plane glass in the bottom of the empty vessel, the point *a* cannot be seen, because the side *Bc* of the vessel interposes; and the point *d* will just be seen over the edge of the vessel at *B*. But if the vessel be filled with water, the point *a* will be seen from *e*; and will appear as at *d*, elevated in the direction of the ray *eB*. Hence a piece of money lying at *e*, in the bottom of an empty vessel, cannot be seen by an eye at *a*, because the edge of the vessel intervenes; but let the vessel be filled with water, and the ray *ea* being then refracted at *B*, will strike the eye at *e*, and so render the money visible, which will appear as if it were raised up to *f* in the line *aBf*.

The time of sun-rising or setting, supposing its rays suffered no refraction, is easily found by calculation. But observation proves, that the sun rises sooner and sets later every day than the calculated time; the reason of which is plain, from what was said immediately above. For, though the sun's rays do not come part of the way to us through water, yet they do through the air or atmosphere, which being a grosser medium than the free space between the sun and the top of the atmosphere, the rays, by entering obliquely into the atmosphere, are there refracted, and thence bent down to the earth. And although there are many places of the earth to which the sun is vertical at noon, and consequently his rays can suffer no refraction at that time, because they come perpendicularly through the atmosphere; yet there is no place to which the sun's rays do not fall obliquely on the top of the atmosphere, at his rising and setting; and consequently, no clear day in which the sun will not be visible before he rises in the horizon, and after he sets in it; and the longer or shorter, as the atmosphere is more or less replete with vapours. For, let *ABC*, (No. 3.) be part of the earth's surface, *DEF* the atmosphere that covers it, and *EBGH* the sensible horizon of an observer at *B*. As every point of the sun's surface sends out rays of light in all manner of directions, some of his rays will constantly fall upon, and enlighten, some half of our atmosphere; and

* Any thing through which the rays of light can pass, is called a medium; as air, water, glass, diamond, or even a vacuum.

and therefore, when the sun is at I , below the horizon H , those rays which go on in the free space IKK preserve a rectilinear course until they fall upon the top of the atmosphere; and those which fall so about K , are refracted at their entrance into the atmosphere, and bent down in the line KmB , to the observer's place at B : and therefore, to him the sun will appear at L , in the direction of the ray BmK , above the horizon BGH , when he is really below it at I .

The angle contained between a ray of light, and a perpendicular to the refracting surface, is called the *angle of incidence*; and the angle contained between the same perpendicular, and the same ray after refraction, is called the *angle of refraction*. Thus (No. 4.) let LBM be the refracting surface of a medium (suppose water,) and ABC a perpendicular to that surface; let DB be a ray of light, going out of air into water at B , and therein refracted in the line BH ; the angle ABD , is the angle of incidence, of which DF is the line; and the angle KBH is the angle of refraction, whose line is KI .

When the refracting medium is water, the sine of the angle of incidence is to the sine of the angle of refraction as 4 to 3; which is confirmed by the following experiment, taken from Doctor SMITH'S Optics.

Describe the circle $DAEC$ on a plane square board, and cross it at right angles with the straight lines ABC , and LBM ; then, from the intersection A , with any opening of the compasses, set off the equal arcs AD and AE , and draw the right line DFE : then, taking Fa , which is three quarters of the length FE , from the point a , draw aI parallel to ABK , and join KI parallel to BM : so KI will be equal to three quarters of FE or of DF . This done, fix the board upright upon the leaden pedestal Q , and stick three pins perpendicularly into the board, at the points D , B , and I : then set the board upright into the vessel TUV , and fill up the vessel with water to the line LBM . When the water has settled, look along the line DB , so as you may see the head of the pin B over the head of the pin D ; and the pin I will appear in the same right line produced to G , for its head will be seen just over the head of the pin at B : which shews that the ray IB , coming from the pin at I , is so refracted at B , as to proceed from thence in the line BD to the eye of the observer; the same as it would do from any point G in the right line DBG , if there were no water in the vessel: and also shews, that KI , the sine of refraction in water, is to DF , the sine of incidence in air, as 3 to 4.

Hence, if DBH were a crooked stick put obliquely into the water, it would appear a straight one at DBG . Therefore, as the line BH appears at BG , so the line BG will appear at Bg ; and consequently, a straight stick DBG put obliquely into water, will seem bent at the surface of the water in B , and crooked, as DBg .

When a ray of light passes out of air into glass, the sine of incidence is to the sine of refraction as 3 to 2; and when out of air into a diamond, as 5 to 2.

OF GLASSES.

GLASS may be ground into eight different shapes at least, for optical purposes, viz.

1. A *plane glass*, (No. 5.) which is flat on both sides, and of equal thickness in all parts, as A .

2. A *plano-convex*, which is flat on one side, and convex on the other, as B .

3. A *double-convex*, which is convex on both sides, as C .

4. A *plano-concave*, which is flat on one side, and concave on the other, as D .

5. A *double-concave*, which is concave on both sides, as E .

6. A *meniscus*, which is concave on one side, and convex on the other, as F .

7. A *flat plano-convex*, whose convex side is ground into several little flat surfaces, as G .

8. A *prism*, which has three flat sides; and when viewed endwise, appears like an equilateral triangle, as H .

Glasses ground into any of the shapes B , C , D , E , F , are generally called *lenses*.

A right line LTK , (No. 6.) going perpendicularly through the middle of a lens, is called the *axis of the lens*.

A ray of light Gh , falling perpendicularly on a plane glass EF , will pass through the glass in the same direction hi , and go out of it into the air in the same right course iH .

A ray of light AB , falling obliquely on a plane glass, will go out of the glass in the same direction, but not in the same right line: for in touching the glass, it will be refracted in the line BC ; and in leaving the glass, it will be refracted in the line CD .

A ray of light CD , (No. 7.) falling obliquely on the middle of a convex glass, will go forward in the same direction DE , as if it had fallen with the same degree of obliquity on a plane glass; and will go out of the glass in the same direction with which it entered: for it will be equally refracted at the points D and E , as if it had passed through a plane surface. But the rays CG and CI will be so refracted, as to meet again at the point F . Therefore, all the rays which flow from the point C , so as to go through the glass, will meet again at F ; and if they go farther onward, as to L , they cross at F , and go forward on the opposite sides of the middle ray $CDEF$, to what they were in approaching it in the directions HF and KF .

When parallel rays, as ABC , (No. 8.) fall directly upon a plano-convex glass DE , and pass through it, they will be so refracted, as to unite in a point f behind it; and this point is called the *principal focus*; the distance of which, from the middle of the glass, is called the *focal distance*, which is equal to twice the radius of the sphere of the glass's convexity. And,

When parallel rays, as ABC , (No. 9.) fall directly upon a glass DE , which is equally convex on both sides, and pass through it; they will be so refracted, as to meet in a point or principal focus f , whose distance is equal to the radius or semidiameter of the sphere of the glass's convexity. But if a glass be more convex on one side than on the other, the rule for finding the focal distance is this: As the sum of the semidiameters of both convexities is to the semidiameter of either, so is double the semidiameter

semidiameter of the other to the distance of the focus. Or, divide the double product of the radii by their sum, and the quotient will be the distance sought.

Since all those rays of the sun which pass through a convex glass are collected together in its focus, the force of all their heat is collected into that part; and is in proportion to the common heat of the sun, as the area of the glass to the area of the focus. Hence we see the reason why a convex glass causes the sun's rays to burn after passing through it.

All these rays cross the middle ray in the focus f , and then diverge from it, to the contrary sides, in the same manner F/G , as they converged in the space D/f in coming to it.

If another glass FG , of the same convexity as DE , be placed in the rays at the same distance from the focus, it will refract them so, as that, after going out of it, they will be all parallel, as abc ; and go on in the same manner as they came to the first glass DE , through the space ABC ; but on the contrary sides of the middle ray B/b : for the ray Adf will go on from f in the direction fGa , and the ray CEf in the direction fFc , and so of the rest.

The rays diverge from any radiant point, as from a principal focus: therefore if a candle be placed at f , in the focus of the convex glass FG , the diverging rays in the space E/f will be so refracted by the glass, as that, after going out of it, they will become parallel, as shewn in the space cba .

If the candle be placed nearer the glass than its focal distance, the rays will converge after passing through the glass more or less as the candle is more or less distant from the focus.

If the candle be placed farther from the glass than its focal distance, the rays will converge after passing through the glass, and meet in a point, which will be more or less distant from the glass as the candle is nearer to or farther from its focus: and where the rays meet, they will form an inverted image of the flame of the candle; which may be seen on a paper placed in the meeting of the rays.

Hence, if any object ABC (No. 10.) be placed beyond the focus F of the convex glass def , some of the rays which flow from every point of the object, on the side next the glass, will fall upon it; and after passing through it, they will be converged into as many points on the opposite side of the glass, where the image of every point will be formed, and consequently the image of the whole object, which will be inverted. Thus, the rays Ad , Ae , Af , flowing from the point A , will converge in the space daf , and by meeting at a will there form the image of the point A . The rays Bb , Be , Bf , flowing from the point B , will be united at b by the refraction of the glass, and will there form the image of the point B . And the rays Cd , Ce , Cf , flowing from the point C , will be united at c , where they will form the image of the point C . And so of all the other intermediate points between A and C . The rays which flow from every particular point of the object, and are united again by the glass, are called *pencils* of rays.

If the object ABC be brought nearer to the glass, the picture abc will be removed to a greater distance. For then more rays flowing from every single point, will all

more diverging upon the glass; and therefore cannot be so soon collected into the corresponding points behind it. Consequently, if the distance of the object ABC (No. 11.) be equal to the distance EB of the focus of the glass, the rays of each pencil will be so refracted by passing through the glass, that they will go out of it parallel to each other; as dI , eH , fb , from the point C ; dG , eK , fD , from the point B ; and dK , eE , fL , from the point A : and therefore, there will be no picture formed behind the glass.

If the focal distance of the glass, and the distance of the object from the glass, be known, the distance of the picture from the glass may be found by this rule, *viz.* Multiply the distance of the focus by the distance of the object, and divide the product by the difference; the quotient will be the distance of the picture.

The picture will be as much bigger or less than the object, as its distance from the glass is greater or less than the distance of the object. For, as Be (No. 10.) is to eB , so is AC to ca . So that if ABC be the object, cba will be the picture; or if cba be the object, ABU will be the picture.

Having described how the rays of light, flowing from objects and passing through convex glasses, are collected into points, and form the images of the objects; it will be easy to understand how the rays are affected by passing through the humours of the eye, and are thereby collected into innumerable points on the bottom of the eye, and thereon form the images of the objects which they flow from. For, the different humours of the eye, and particularly the chrystalline humour, are to be considered as a convex glass; and the rays in passing through them to be affected in the same manner as in passing through a convex glass.—For a description of the coats and tumours of the eye, see ANATOMY, p. 289.

As every point of an object ABC , (No. 12.) sends out rays in all directions, some rays, from every point on the side next the eye, will fall upon the cornea between E and F ; and by passing on through the humours and pupil of the eye, they will be converged to as many points on the retina or bottom of the eye, and will thereon form a distinct inverted picture cba of the object. Thus, the pencil of rays grs that flows from the point A of the object, will be converged to the point a on the retina; those from the point B will be converged to the point b ; those from the point C will be converged to the point c ; and so of all the intermediate points; by which means the whole image abc is formed, and the object made visible: although it must be owned, that the method by which this sensation is carried from the eye by the optic nerve to the common sensory in the brain, and there discerned, is above the reach of our comprehension.

But that vision is effected in this manner, may be demonstrated experimentally. Take a bullock's eye whilst it is fresh, and having cut off the three coats from the back part, quite to the vitreous humour, put a piece of white paper over that part, and hold the eye towards any bright object, and you will see an inverted picture of the object upon the paper.

Since the image is inverted, many have wondered why the object appears upright. But we are to consider,

1. That *inverted* is only a relative term; and, 2. That there

there is a very great difference between the real object and the means or image by which we perceive it. When all the parts of a distant prospect are painted upon the retina, they are all right with respect to one another, as well as the parts of the prospect itself; and we can only judge of an object's being inverted, when it is turned reverse to its natural position with respect to other objects which we see and compare it with.—If we lay hold of an upright stick in the dark, we can tell which is the upper or lower part of it, by moving our hand downward or upward; and know very well that we cannot feel the upper end by moving our hand downward. Just so we find by experience, that upon directing our eyes towards a tall object, we cannot see its top by turning our eyes downward, nor its foot by turning our eyes upward; but must trace the object the same way by the eye to see it from head to foot, as we do by the hand to feel it; and as the judgment is informed by the motion of the hand in one case, so it is also by the motion of the eye in the other.

In (No. 13.) is exhibited the manner of seeing the same object *ABC*, by both the eyes *D* and *E* at once.

When any part of the image *cha* falls upon the optic nerve *L*, the corresponding part of the object becomes invisible. On which account, nature has wisely placed the optic nerve of each eye, not in the middle of the bottom of the eye, but towards the side next the nose; so that whatever part of the image falls upon the optic nerve of one eye, may not fall upon the optic nerve of the other. Thus the point *a* of the image *cha* falls upon the optic nerve of the eye *D*, but not of the eye *E*; and the point *c* falls upon the optic nerve of the eye *E*, but not of the eye *D*: and therefore, to both eyes taken together, the whole object *ABC* is visible.

The nearer that any object is to the eye, the larger is the angle under which it is seen, and the magnitude under which it appears. Thus to the eye *D*, (No. 14.) the object *ABC* is seen under the angle *APC*; and its image *cha* is very large upon the retina: but to the eye *E*, at a double distance, the same object is seen under the angle *ApC*, which is equal only to half the angle *APC*, as is evident by the figure. The image *cha* is likewise twice as large in the eye *D*, as the other image *cha* is in the eye *E*. In both these representations, a part of the image falls on the optic nerve, and the object in the corresponding part is invisible.

As the sense of seeing is allowed to be occasioned by the impulse of the rays from the visible object upon the retina of the eye, and forming the image of the object thereon, and that the retina is only the expansion of the optic nerve all over the choroides; it should seem surprising, that the part of the image which falls on the optic nerve should render the like part of the object invisible; especially as that nerve is allowed to be the instrument by which the impulse and image are conveyed to the common sensory in the brain. But this difficulty vanishes, when we consider that there is an artery within the trunk of the optic nerve, which entirely obscures the image in that part, and conveys no sensation to the brain.

That the part of the image which falls upon the middle of the optic nerve is lost, and consequently the correspond-

ing part of the object is rendered invisible, is plain by experiment. For, if a person fixes three patches, *A, B, C*, (No. 15.) upon a white wall, at the height of the eye, and the distance of about a foot from each other, and places himself before them, shutting the right eye, and directing the left towards the patch *C*, he will see the patches *A* and *C*, but the middle patch *B* will disappear. Or, if he shuts his left eye, and directs the right towards *A*, he will see both *A* and *C*, but *B* will disappear; and if he directs his eye towards *B*, he will see both *B* and *C*, but not *A*. For whatever patch is directly opposite to the optic nerve *N*, vanishes. This requires a little practice, after which he will find it easy to direct his eye, so as to lose the sight of whichever patch he pleases.

We are not commonly sensible of this disappearance, because the motions of the eye are so quick and instantaneous, that we no sooner lose the sight of any part of an object, than we recover it again; much the same as in the twinkling of our eyes; for at each twinkling we are blinded; but it is so soon over, that we are scarce ever sensible of it.

Some eyes require the assistance of convex glasses to make them see objects distinctly, and others of concave. If either the cornea *abc*, (No. 16.) or crystalline humour *e*, or both of them, be too flat, as in the eye *A*, their focus will not be on the retina, as at *d*, where it ought to be, in order to render vision distinct; but beyond the eye, as at *f*. And therefore, those rays which flow from the object *C*, and pass through the humours of the eye, are not converged enough to unite at *d*; and therefore the observer can have but a very indistinct view of the object. This is remedied by placing a convex glass *gh* before the eye, which makes the rays converge sooner, and imprints the image duly on the retina at *d*.

If either the cornea, or crystalline humour, or both of them, be too convex, as in the eye *B*, the rays that enter it from the object *C*, will be converged to a focus in the vitreous humour, as at *f*, and by diverging from thence to the retina, will form a very confused image thereon: and so, of course, the observer will have as confused a view of the object, as if his eye had been too flat. This inconvenience is remedied by placing a concave glass *gh* before the eye; which glass, by causing the rays to diverge between it and the eye, lengthens the focal distance so; that if the glass be properly chosen, the rays will unite at the retina, and form a distinct picture of the object upon it.

Such eyes as have their humours of a due convexity, cannot see any object distinctly at a less distance than six inches; and there are numberless objects too small to be seen at that distance, because they cannot appear under any sensible angle. The method of viewing such minute objects is by a microscope; of which there are three sorts, viz. the single, the double, and the solar.

Of MICROSCOPES.

The single microscope is only a small convex glass, as *cd*, (No. 17.) having the object *ab* placed in its focus, and the eye at the same distance on the other side; so that the rays of each pencil, flowing from every point of the object on the side next the glass, may go on parallel

parallel to the eye after passing through the glass; and then, by entering the eye at *C*, they will be converged to as many different points on the retina, and form a large inverted picture *AB* upon it, as in the figure.

To find how much this glass magnifies, divide the least distance (which is about six inches) at which an object can be seen distinctly with the bare eye, by the focal distance of the glass; and the quotient will shew how much the glass magnifies the diameter of the object.

The *double or compound microscope*, (No. 18.) consists of an object-glass *cd*, and an eye-glass *ef*. The small object *ab* is placed at a little greater distance from the glass *cd* than its principal focus, so that the pencils of rays flowing from the different points of the object, and passing through the glass, may be made to converge and unite in as many points between *g* and *h*, where the image of the object will be formed: which image is viewed by the eye through the eye-glass *ef*. For the eye-glass being so placed, that the image *gh* may be in its focus, and the eye much about the same distance on the other side, the rays of each pencil will be parallel, after going out of the eye-glass, as at *e* and *f*, till they come to the eye at *k*, where they will begin to converge by the refractive power of the humours; and after having crossed each other in the pupil, and passed through the chryselline and vitreous humours, they will be collected into point *s* on the retina, and form the large inverted image *AB* thereon.

The magnifying power of this microscope is as follows. Suppose the image *gh* to be six times the distance of the object *ab* from the object-glass *cd*; then will the image be six times the length of the object: but since the image could not be seen distinctly by the bare eye at a less distance than six inches, if it be viewed by an eye-glass *ef*, of one inch focus, it will thereby be brought six times nearer the eye; and consequently viewed under an angle six times as large as before; so that it will be again magnified six times; that is, six times by the object-glass, and six times by the eye glass; which multiplied into one another, makes 36 times; and so much is the object magnified in diameter more than what it appears to the bare eye; and consequently 36 times 36, or 1296 times, in surface.

But, because the extent or field of view is very small in this microscope, there are generally two eye-glasses placed sometimes close together, and sometimes an inch asunder; by which means, although the object appears less magnified, yet the visible area is much enlarged by the interposition of a second eye-glass, and consequently a much pleasanter view is obtained.

The *solar microscope*, (No. 19.) invented by Dr Lieberkühn, is constructed in the following manner. Having procured a very dark room, let a round hole be made in the window-shutter, about three inches diameter, through which the sun may cast a cylinder of rays *AA* into the room. In this hole, place the end of a tube, containing two convex glasses and an object, *viz.* 1. A convex glass *aa*, of about two inches diameter, and three inches focal distance, is to be placed in that end of the tube which is put into the hole. 2. The object *bb*, being put between two glasses (which must be concave to hold it at liberty)

is placed about two inches and a half from the glass *aa*. 3. A little more than a quarter of an inch from the object is placed the small convex glass *cc*, whose focal distance is a quarter of an inch.

The tube may be so placed, when the sun is low, that his rays *AA* may enter directly into it: but when he is high, his rays *BB* must be reflected into the tube by the plane mirror or looking glass *CC*.

Things being thus prepared, the rays that enter the tube will be conveyed by the glass *aa* towards the object *bb*, by which means it will be strongly illuminated; and the rays *d* which flow from it through the convex glass *cc*, will make a large inverted picture of the object at *DD*, which, being received on a white paper, will represent the object magnified in length, in proportion of the distance of the picture from the glass *cc*, to the distance of the object from the same glass. Thus, suppose the distance of the object from the glass to be $\frac{1}{12}$ parts of an inch, and the distance of the distinct picture to be 12 feet or 144 inches, in which there are 1440 tenths of 24 inch; and this number divided by 3 tenths, gives 480; which is the number of times the picture is longer or broader than the object; and the length multiplied by the breadth, shews how much the whole surface is magnified.

OF TELESCOPES.

BEFORE we enter upon the description of telescopes, it will be proper to shew how the rays of light are affected by passing through concave glasses, and also by falling upon concave mirrors.

When parallel rays, as *abcd, fgh*, (No. 20.) pass directly through a glass *AB*, which is equally concave on both sides, they will diverge after passing through the glass, as if they had come from a radiant point *C*, in the centre of the glass's concavity; which point is called the negative or virtual focus of the glass. Thus the ray *a*, after passing through the glass *AB*, will go on in the direction *kl*, as if it had proceeded from the point *C*, and no glass been in the way. The ray *b* will go on in the direction *mn*; the ray *c* in the direction *op*, &c.—The ray *C*, that falls directly upon the middle of the glass, suffers no refraction in passing through it; but goes on in the same rectilinear direction, as if no glass had been in its way.

If the glass had been concave only on one side, and the other side quite plane, the rays would have diverged, after passing through it, as if they had come from a radiant point at double the distance of *C* from the glass; that is, as if the radiant had been at the distance of a whole diameter of the glass's concavity.

If rays come more converging to such a glass, than parallel rays diverge after passing through it, they will continue to converge after passing through it; but will not meet so soon as if no glass had been in the way, and will incline towards the same side to which they would have diverged if they had come parallel to the glass. Thus the rays *f* and *h*, going in a converging state towards the edge of the glass at *B*, and converging more in their way to it than the parallel rays diverge after passing through it, they will go on converging after they pass through it,

through

though in a less degree than they did before, and will meet at i : but if no glass has been in their way, they would have met at i .

When parallel rays, (No. 21.) as dfa , Cmb , &c, fall upon a concave mirror AB (which is not transparent, but has only the surface AB of a clear polish,) they will be reflected back from that mirror, and meet in a point m , at half the distance of the surface of the mirror from C the centre of its concavity; for they will be reflected at as great an angle from a perpendicular to the surface of the mirror, as they fell upon it with regard to that perpendicular, but on the other side thereof. Thus, let C be the centre of concavity of the mirror AB ; and let the parallel rays dfa , Cmb , and etc , fall upon it at the points a , b , and c . Draw the lines Cia , Cmb , and Cbc , from the centre C to these points; and all these lines will be perpendicular to the surface of the mirror, because they proceed thereto like so many radii or spokes from its centre. Make the angle Cab equal to the angle daC , and draw the line amb , which will be the direction of the ray dfa , after it is reflected from the point a of the mirror; so that the angle of incidence daC , is equal to the angle of reflection Cab ; the rays making equal angles with the perpendicular Cia on its opposite sides.

Draw also the perpendicular Cbc to the point c , where the ray etc touches the mirror; and, having made the angle Cci equal to the angle Cce , draw the line cmi , which will be the course of the ray etc , after it is reflected from the mirror.

The ray Cmb passing through the centre of concavity of the mirror, and falling upon it at b , is perpendicular to it; and is therefore reflected back from it in the same line bmc .

All these reflected rays meet in the point m ; and in that point the image of the body which emits the parallel rays da , Cb , and ec , will be formed; which point is distant from the mirror equal to half the radius bmc of its concavity.

The rays which proceed from any celestial object may be esteemed parallel at the earth; and therefore, the images of that object will be formed at m , when the reflecting surface of the concave mirror is turned directly towards the object. Hence, the focus m of parallel rays is not in the centre of the mirror's concavity, but half way between the mirror and that centre.

The rays which proceed from any remote terrestrial object, are nearly parallel at the mirror; not strictly so, but come diverging to it, in separate pencils, or, as it were, bundles of rays, from each point of the side of the object next the mirror; and therefore they will not be converged to a point at the distance of half the radius of the mirror's concavity from its reflecting surface, but into separate points at a little greater distance from the mirror. And the nearer the object is to the mirror, the farther these points will be from it; and an inverted image of the object will be formed in them, which will seem to hang pendant in the air; and will be seen by an eye placed beyond it (with regard to the mirror) in all respects like the object, and as distinct as the object itself.

Let AcB , (No. 22.) be the reflecting surface of a mirror, whose centre of concavity is at C ; and let the upright object DE be placed beyond the centre C , and send out a conical pencil of diverging rays from its upper extremity D , to every point of the concave surface of the mirror AcB . But to avoid confusion, we only draw three rays of that pencil, as DA , Dc , DB .

From the centre of concavity C , draw the three right lines CA , Cc , CB , touching the mirror in the same points where the foresaid rays touch it; and all these lines will be perpendicular to the surface of the mirror. Make the angle CAd equal to the angle DAC , and draw the right line Ad for the course of the reflected ray DA : make the angle Ccd equal to the angle DcC , and draw the right line cd for the course of the reflected ray Dc : make also the angle CBd equal to the angle DBC , and draw the right line Bb for the course of the reflected ray DB . All these reflected rays will meet in the point d , where they will form the extremity d of the inverted image ed , similar to the extremity D of the upright object DE .

If the pencil of rays Eg , Eh , be also continued to the mirror, and their angles of reflection from it be made equal to their angles of incidence upon it, as in the former pencil from D , they will all meet at the point e by reflection, and form the extremity e of the image ed , similar to the extremity E of the object DE .

And as each intermediate point of the object, between D and E , sends out a pencil of rays in like manner to every part of the mirror, the rays of each pencil will be reflected back from it, and meet in all the intermediate points between the extremities e and d of the image; and so the whole image will be formed, not at i , half the distance of the mirror from its centre of concavity C ; but at a greater distance, between i and the object DE ; and the image will be inverted with respect to the object.

This being well understood, the reader will easily see how the image is formed by the large concave mirror of the reflecting telescope, when he comes to the description of that instrument.

When the object is more remote from the mirror than its centre of concavity C , the image will be less than the object, and between the object and mirror: when the object is nearer than the centre of concavity, the image will be more remote and bigger than the object: thus, if DE be the object, ed will be its image: for, as the object recedes from the mirror, the image approaches nearer to it; and as the object approaches nearer to the mirror, the image recedes farther from it; on account of the lesser or greater divergency of the pencils of rays which proceed from the object: for, the less they diverge, the sooner they are converged to points by reflection; and the more they diverge, the farther they must be reflected before they meet.

If the radius of the mirror's concavity, and the distance of the object from it, be known, the distance of the image from the mirror is found by this rule; Divide the product of the distance and radius by double the distance made less by the radius, and the quotient is the distance required.

If the object be in the centre of the mirror's concavity,

cavity, the image and object will be coincident, and equal in bulk.

If a man places himself directly before a large concave mirror, but farther from it than its centre of concavity, he will see an inverted image of himself in the air, between him and the mirror, of a less size than himself. And if he holds out his hand towards the mirror, the hand of the image will come out towards his hand, and coincide with it, of an equal bulk, when his hand is in the centre of concavity; and he will imagine he may shake hands with his image. If he reaches his hand farther, the hand of the image will pass by his hand, and come between his hand and his body: and if he moves his hand towards either side, the hand of the image will move towards the other; so that whatever way the object moves, the image will move the contrary.

All the while a by-stander will see nothing of the image, because none of the reflected rays that form it enter his eyes.

If a fire be made in a large room, and a smooth mahogany table be placed at a good distance near the wall, before a large concave mirror, so placed, that the light of the fire may be reflected from the mirror to its focus upon the table; if a person stands by the table, he will see nothing upon it but a longish beam of light: but if he stands at a distance towards the fire, not directly between the fire and mirror, he will see an image of the fire upon the table, large and erect. And if another person, who knows nothing of this matter before-hand, should chanceto come into the room, and should look from the fire towards the table, he would be startled at the appearance; for the table would seem to be on fire, and, by being near the waistcoat, to endanger the whole house. In this experiment, there should be no light in the room but what proceeds from the fire; and the mirror ought to be at least fifteen inches in diameter.

If the fire be darkened by a screen, and a large candle be placed at the back of the screen; a person standing by the candle will see the appearance of a fine large star, or rather planet, upon the table, as bright as Venus or Jupiter. And if a small wax taper (whose flame is much less than the flame of the candle) be placed near the candle, a satellite to the planet will appear on the table: and if the taper be moved round the candle, the satellite will go round the planet.

In a *refracting telescope*, the glass which is nearest the object in viewing it is called the *object-glass*, and that which is nearest the eye is called the *eye-glass*. The object-glass must be convex, but the eye-glass may be either convex or concave: and generally, in looking through a telescope, the eye is in the focus of the eye-glass; though that is not very material: for the distance of the eye, as to distinct vision, is indifferent, provided the rays of the pencils fall upon it parallel: only, the nearer the eye is to the end of the telescope, the larger is the scope or area of the field of view.

Let cd (No. 23.) be a convex glass fixed in a long tube, and have its focus at E . Then, a pencil of rays ghi , flowing from the upper extremity A of the remote object AB , will be so refracted by passing through the glass, as to converge and meet in the point f ; whilst the pencil of rays klm , flowing from the lower extremity B of the

same object AB , and passing through the glass, will converge and meet in the point e : and the images of the points A and B will be formed in the points f and e . And as all the intermediate points of the object, between A and B , send out pencils of rays in the same manner, a sufficient number of these pencils will pass through the object-glass cd , and converge to as many intermediate points between e and f ; and so will form the whole inverted image eFf of the distinct object. But because this image is small, a concave glass no is so placed in the end of the tube next the eye, that its virtual focus may be at F . And as the pencils of rays pass converging through the concave glass, but converge less after passing through it than before, they go on further, as to b and a , before they meet; and the pencils themselves being made to diverge by passing through the concave glass, they enter the eye, and form the large picture ab upon the retina, whereon it is magnified under the angle bFa .

But this telescope has one inconvenience which renders it unfit for most purposes, which is, that the pencils of rays being made to diverge by passing through the concave glass no , very few of them can enter the pupil of the eye; and therefore the field of view is but very small, as is evident by the figure. For none of the pencils which flow either from the top or bottom of the object AB can enter the pupil of the eye at C , but are all stoppt by falling upon the iris above and below the pupil: and therefore, only the middle part of the object can be seen when the telescope lies directly towards it, by means of those rays which proceed from the middle of the object. So that to see the whole of it, the telescope must be moved upwards and downwards, unless the object be very remote; and then it is never seen distinctly.

This inconvenience is remedied by substituting a convex eye-glass, as gh , (No. 24.) in place of the concave one; and fixing it so in the tube, that its focus may be coincident with the focus of the object-glass cd , as at E . For then, the rays of the pencils flowing from the object AB , and passing through the object-glass cd , will meet in its focus, and form the inverted image mEp : and as the image is formed in the focus of the eye-glass gh , the rays of each pencil will be parallel, after passing through that glass; but the pencils themselves will cross in its focus on the other side, as at e : and the pupil of the eye being in this focus, the image will be viewed through the glass, under the angle geb : and being at E , it will appear magnified, so as to fill the whole space $CmepD$.

But, as this telescope inverts the image with respect to the object, it gives an unpleasant view of terrestrial objects; and is only fit for viewing the heavenly bodies, in which we regard not their position, because their being inverted does not appear on account of their being round. But whatever way the object seems to move, this telescope must be moved the contrary way, in order to keep sight of it; for, since the object is inverted, its motion will be so too.

The magnifying power of this telescope is as the focal distance of the object-glass to the focal distance of the eye-glass. Therefore, if the former be divided by the latter, the quotient will express the magnifying power.

When we speak of the magnifying of a telescope or microscope,

scope, it is only meant with regard to the diameter, not to the area nor solidity of the object. But as the instrument magnifies the vertical diameter, as much as it does the horizontal, it is easy to find how much the whole visible area or surface is magnified: for, if the diameters be multiplied into one another, the product will express the magnification of the whole visible area. Thus, suppose the focal distance of the object-glass be ten times as great as the focal distance of the eye-glass; then, the object will be magnified ten times, both in length and breadth: and 10 multiplied by 10, produces 100; which shews, that the area of the object will appear 100 times as big when seen through such a telescope, as it does to the bare eye.

Hence it appears, that if the focal distance of the eye-glasses were equal to the focal distance of the object-glasses, the magnifying power of the telescope would be nothing.

This telescope may be made to magnify in any given degree, provided it be of a sufficient length. For, the greater the focal distance of the object-glass, the less may be the focal distance of the eye-glass; though not directly in proportion. Thus, an object-glass, of 10 feet focal distance, will admit of an eye-glass whose focal distance is little more than $2\frac{1}{2}$ inches; which will magnify near 48 times: but an object-glass, of 100 feet focus, will require an eye-glass somewhat more than 6 inches; and will therefore magnify almost 200 times.

A telescope for viewing terrestrial objects, should be so constructed, as to shew them in their natural posture. And this is done by one object-glass *cd*, (No. 25.) and three eye-glasses *ef, gh, ik*, so placed, that the distance between any two, which are nearest to each other, may be equal to the sum of their focal distances; as in the figure, where the focus of the glasses *cd* and *ef* meet at *F*, those of the glasses *ef* and *gh* meet at *l*, and of *gh* and *ik* at *m*; the eye being at *n*, in or near the focus of the eye-glass *ik*, on the other side. Then, it is plain, that these pencils of rays, which flow from the object *AB*, and pass through the object-glass *cd*, will meet and form an inverted image *CFD* in the focus of that glass; and the image being also in the focus of the glass *ef*, the rays of the pencils will become parallel, after passing through that glass, and cross at *l*, in the focus of the glass *ef*; from whence they pass on to the next glass *gh*, and by going through it they are converged to points in its other focus, where they form an erect image *EmF* of the object *AB*: and as this image is also in the focus of the eye-glass *ik*, and the eye on the opposite side of the same glass; the image is viewed through the eye glass in this telescope, in the same manner as through the eye-glass in the former one; only in a contrary position, that is, in the same position with the object.

The three glasses next the eye have all their focal distances equal: and the magnifying power of this telescope is found the same way as that of the last above; viz. by dividing the focal distance of the object-glass *cd*, by the focal distance of the eye-glass *ik*, or *gh*, or *ef*, since all these three are equal.

When the rays of light are separated by refraction, they become coloured; and if they be united again, they will be a perfect white. But those rays which pass

through a convex glass near its edges are more unequally refracted than those which are nearer the middle of the glass. And when the rays of any pencil are unequally refracted by the glass, they do not all meet again in one and the same point, but in separate points; which makes the image indistinct, and coloured, about its edges. The remedy is, to have a plate with a small round hole in its middle, fixed in the tube at *m*, parallel to the glasses. For, the wandering rays about the edges of the glasses will be stopp'd, by the plate, from coming to the eye; and none admitted but those which come through the middle of the glass, or at least at a good distance from its edges, and pass through the hole in the middle of the plate. But this circumscribes the image, and lessens the field of view, which would be much larger if the plate could be dispensed with.

The great inconvenience attending the management of long telescopes of this kind, has brought them much into disuse ever since the reflecting telescope was invented. For one of this sort, six feet in length, magnifies as much as one of the other an hundred. It was invented by Sir *Isaac Newton*, but has received considerable improvements since his time; and is now generally constructed in the following manner, which was first proposed by Dr. *Gregory*.

At the bottom of the great tube *TTTT*, (No. 26.) is placed the large concave mirror *DUVF*, whose principal focus is at *m*; and in its middle is a round hole *P*, opposite to which is placed the small mirror *L*, concave toward the great one; and so fixed to a strong wire *M*, that it may be moved farther from the great mirror, or nearer to it, by means of a long screw on the outside of the tube, keeping its axis still in the same line *Pmn* with that of the great one.—Now, since in viewing a very remote object, we can scarce see a point of it but what is at least as broad as the great mirror, we may consider the rays of each pencil, which flow from every point of the object, to be parallel to each other, and to cover the whole reflecting surface *DUVF*. But to avoid confusion in the figure, we shall only draw two rays of a pencil flowing from each extremity of the object into the great tube, and trace their progress, through all their reflections, and refractions, to the eye *f*, at the end of the small tube *tt*, which is joined to the great one.

Let us then suppose the object *AB* to be at such a distance, that the rays *B* may flow from its lower extremity *B*, and the rays *E* from its upper extremity *A*. Then the rays *C* falling parallel upon the great mirror at *D*, will be thence reflected converging, in the direction *DG*; and by crossing at *l* in the principal focus of the mirror, they will form the upper extremity *l* of the inverted image *IK*, similar to the lower extremity *B* of the object *AB*: and passing on to the concave mirror *L* (whose focus is at *n*) they will fall upon it at *g*, and be thence reflected converging, in the direction *gN*, because *gm* is longer than *gn*; and passing through the hole *P* in the large mirror, they would meet somewhere about *r*, and form the lower extremity *B* of the erect image *AB*, similar to the lower extremity *B* of the object *AB*. But by passing through the plano-convex glass *R* in their way, they form that extremity of the image at *b*. In like manner, the rays *E*, which come from the top of the object

AB , and fall parallel upon the great mirror at F , are thence reflected converging to its focus, where they form the lower extremity K of the inverted image IK , similar to the upper extremity A of the object AB ; and thence passing on to the small mirror L , and falling upon it at h , they are thence reflected in the converging state hO ; and going on through the hole P of the great mirror, they would meet somewhere about g , and form there the upper extremity a of the erect image ab , similar to the upper extremity A of the object AB : but by passing through the convex glass R in their way, they meet and cross sooner, as at a , where that point of the erect image is formed.—The like being understood of all those rays which flow from the intermediate points of the object between A and B , and enter the tube TT ; all the intermediate points of the image between a and b will be formed; and the rays passing on from the image, through the eye-glass S , and through a small hole e in the end of the lesser tube tt , they enter the eye f , (which sees the image ab by means of the eye-glass) under the large angle ced , and magnified in length under that angle from c to d .

In the best reflecting telescopes, the focus of the small mirror is never coincident with the focus m of the great one, where the first image IK is formed, but a little beyond it (with respect to the eye) as at n : the consequence of which is, that the rays of the pencils will not be parallel after reflection from the small mirror, but converge so as to meet in points about g, e, r ; where they would form a larger upright image than ab , if the glass R was not in their way; and this image might be viewed by means of a single eye-glass properly placed between the image and the eye; but then the field of view would be less, and consequently not so pleasant; for which reason, the glass R is still retained, to enlarge the scope or area of the field.

To find the magnifying power of this telescope, multiply the focal distance of the great mirror by the distance of the small mirror from the image next the eye, and multiply the focal distance of the small mirror by the focal distance of the eye-glass; then, divide the product of the former multiplication by the product of the latter, and the quotient will express the magnifying power.

We shall here set down the dimensions of one of Mr. Short's reflecting telescopes, as described in Dr. Smith's optics.

The focal distance of the great mirror 9.6 inches, its breadth 2.3; the focal distance of the small mirror 1.5, its breadth 0.6; the breadth of the hole in the great mirror 0.5; the distance between the small mirror and the next eye-glass 14.2; the distance between the two eye-glasses 2.4; the focal distance of the eye-glass next the metals 3.8; and the focal distance of the eye-glass next the eye 1.1.

One great advantage of the reflecting telescope is, that it will admit of an eye-glass of a much shorter focal distance than a refracting telescope will; and, consequently, it will magnify so much the more: for the rays are not coloured by reflection from a concave mirror, if it be ground to a true figure, as they are by passing through a convex glass, let it be ground ever so true.

The adjusting screw on the outside of the great tube

fits this telescope to all sorts of eyes, by bringing the small mirror either nearer to the eye, or removing it farther; by which means, the rays are made to diverge a little for short-sighted eyes, or to converge for those of a long sight.

The nearer an object is to the telescope, the more its pencils of rays will diverge before they fall upon the great mirror, and therefore they will be the longer of meeting in points after reflection; so that the first image IK will be formed at a greater distance from the large mirror, when the object is near the telescope, than when it is very remote. But as this image must be formed farther from the small mirror than its principal focus n , this mirror must be always set at a greater distance from the large one, in viewing near objects, than in viewing remote ones. And this is done by turning the screw on the outside of the tube, until the small mirror be so adjusted, that the object (or rather its image) appears perfect.

In looking through any telescope towards an object, we never see the object itself, but only that image of it which is formed next the eye in the telescope. For if a man holds his finger or a stick between his bare eye and an object, it will hide part (if not the whole) of the object from his view. But if he ties a stick across the mouth of a telescope before the object-glass, it will hide no part of the imaginary object he saw through the telescope before, unless it covers the whole mouth of the tube: for, all the effect will be, to make the object appear dimmer, because it intercepts part of the rays. Whereas, if he puts only a piece of wire across the inside of the tub, between the eye-glass and his eye, it will hide part of the object which he thinks he sees: which proves, that he sees not the real object, but its image. This is also confirmed by means of the small mirror L , in the reflecting telescope, which is made of opaque metal, and stands directly between the eye and the object towards which the telescope is turned; and will hide the whole object from the eye at e , if the two glasses R and S are taken out of the tube.

Of the MULTIPLYING GLASS.

THE multiplying glass is made by grinding down the round side lik (No. 27.) of a convex glass AB , into several flat surfaces, as bb, bld, dk . An object C will not appear magnified when seen through this glass by the eye at H ; but it will appear multiplied into as many different objects as the glass contains plane surfaces. For, since rays will flow from the object C to all parts of the glass, and each plane surface will refract these rays to the eye, the same object will appear to the eye in the direction of the rays which enter it through each surface. Thus, a ray giH , falling perpendicularly on the middle surface, will go through the glass to the eye without suffering any refraction; and will therefore shew the object in its true place at C : whilst a ray ab flowing from the same object, and falling obliquely on the plane surface bb , will be refracted in the direction be , by passing through the glass; and upon leaving it, will go on to the eye in the direction eH ; which will cause the same object C to appear also at E , in the direction of the ray He , produced in the right line Hen . And the ray cd , flowing from the

The object *C*, and falling obliquely on the plane surface *dt*, will be refracted (by passing through the glass and leaving it at *f*) to the eye at *H*; which will cause the same object to appear at *D*, in the direction *Hfm*.—If the glass be turned round the line *ghl*, as an axis, the object *C* will keep its place, because the surface *blid* is not removed; but all the other objects will seem to go round *C*, because the oblique planes, on which the rays *ab ed* fall, will go round by the turning of the glass.

Of the CAMERA OBSCURA.

THE camera obscura is made by a convex-glass *CD*, (No. 28.) placed in a hole of a window-shutter. Then, if the room be darkened so, as no light can enter but what comes through the glass, the pictures of all the objects (as fields, trees, buildings, men, cattle, &c.) on the outside, will be shewn in an inverted order, on a white paper placed at *GH* in the focus of the glass; and will afford a most beautiful and perfect piece of perspective or landscape of whatever is before the glass, especially if the sun shines upon the objects.

If the convex glass *CD* be placed in a tube in the side of a square box, within which is the plane mirror *EP*, reclining backwards in an angle of 45 degrees from the perpendicular *kg*, the pencils of rays flowing from the outward objects, and passing through the convex glass to the plane mirror, will be reflected upwards from it, and meet in points, as *I* and *K* (at the same distance that they would have met at *H* and *C*, if the mirror had not been in the way,) and will form the aforesaid images on an oiled paper stretched horizontally in the direction *IK*; on which paper, the out-lines of the images may be easily drawn with a black-lead pencil; and then copied on a clean sheet, and coloured by art, as the objects themselves are by nature.—In this machine, it is usual to place a plane glass, unpolished, in the horizontal situation *IK*, which glass receives the images of the outward objects; and their outlines may be traced upon it by a black-lead pencil.

N. B. The tube in which the convex glass *CD* is fixed, must be made to draw out, or push in, so as to adjust the distance of that glass from the plane mirror, in proportion to the distance of the outward objects, which the operator does, until he sees their images distinctly pointed on the horizontal glass at *IK*.

The forming a horizontal image, as *IK*, of an upright object *AB*, depends upon the angles of incidence of the rays upon the plane mirror *EP*, being equal to their angles of reflection from it. For, if a perpendicular be supposed to be drawn to the surface of the plane mirror at *e*, where the ray *AaGe* falls upon it, that ray will be reflected upwards in an equal angle with the other side of the perpendicular, in the line *edl*. Again, if a perpendicular be drawn to the mirror from the point *f*, where the ray *Abf* falls upon it, that ray will be reflected in an equal angle from the other side of the perpendicular, in the line *fhI*. And if a perpendicular be drawn from the point *g*, where the ray *Aeg* falls upon the mirror, that ray will be reflected in an equal angle from the other side of the perpendicular, in the line *gil*. So that all the rays of the pencil *abc*, flowing from the upper extremi-

ty of the object *AB*, and passing through the convex glass *CD*, to the plane mirror *EP*, will be reflected from the mirror, and meet at *I*, where they will form the extremity *I* of the image *IK*, similar to the extremity *A* of the object *AB*. The like is to be understood of the pencil *qrs*, flowing from the lower extremity of the object *AB*, and meeting at *K* (after reflection from the plane mirror) the rays form the extremity *K* of the image, similar to the extremity *B* of the object: and so of all the pencils that flow from the intermediate points of the object to the mirror, through the convex glass.

Of the OPERA-GLASS.

If a convex glass, of a short focal distance, be placed near the plane mirror in the end of a short tube, and a convex glass be placed in a hole in the side of the tube, so as the image may be formed between the last mentioned convex glass and the plane mirror; the image being viewed through this glass, will appear magnified.—In this manner, the opera-glasses are constructed; with which a gentleman may look at any lady at a distance in the company, and the lady know nothing of it.

Of the Common LOOKING-GLASS.

THE image of any object that is placed before a plane mirror appears as big to the eye as the object itself; and is erect, distinct, and seemingly as far behind the mirror, as the object is before it: and that part of the mirror, which reflects the image of the object to the eye (the eye being supposed equally distant from the glass with the object) is just half as long and half as broad as the object itself. Let *AB* (No. 29.) be an object placed before the reflecting surface *ghi* of the plain mirror *CD*; and let the eye be at *o*. Let *Ab* be a ray of light flowing from the top *A* of the object and falling upon the mirror at *b*, and *bm* be a perpendicular to the surface of the mirror at *b*; the ray *Ab* will be reflected from the mirror to the eye at *o*, making an angle *mbo* equal to the angle *Abm*: then will the top of the image *E* appear to the eye in the direction of the reflected ray *ob* produced to *E*, where the right line *ApE*, from the top of the object, cuts the right line *obE*, at *E*. Let *Bi* be a ray of light proceeding from the foot of the object at *B* to the mirror at *i*; and *ni* a perpendicular to the mirror from the point *i*, where the ray *Bi* falls upon it: this ray will be reflected in the line *io*, making an angle *nio*, equal the angle *Bin*, with that perpendicular, and entering the eye at *o*; then will the foot *F* of the image appear in the direction of the reflected ray *oi*, produced to *F*, where the right line *BF* cuts the reflected ray produced to *F*. All the other rays that flow from the intermediate points of the object *AB*, and fall upon the mirror between *b* and *i*, will be reflected to the eye at *o*; and all the intermediate points of the image *EF* will appear to the eye in the direction of these reflected rays produced. But all the rays that flow from the object, and fall upon the mirror above *b*, will be reflected back above the eye at *o*; and all the rays that flow from the object, and fall upon the mirror below *i*, will be reflected back below the

the eye at c : so that none of the rays that fall above b , or below i , can be reflected to the eye at c ; and the distance between b and i is equal to half the length of the object AB .

Hence it appears, that if a man sees his whole image in a plane looking-glass, the part of the glass that reflects his image must be just half as long and half as broad as himself, let him stand at any distance from it whatever; and that his image must appear just as far behind the glass as he is before it. Thus, the man AB (No. 30.) viewing himself in the plane mirror CD , which is just half as long as himself, sees his whole image as at EF , behind the glass, exactly equal to his own size. For, a ray AC , proceeding from his eye at A , and falling perpendicularly upon the surface of the glass at C , is reflected back to his eye, in the same line CA ; and the eye of his image will appear at E , in the same line produced to E , beyond the glass. And a ray BD , flowing from his foot, and falling obliquely on the glass at D , will be reflected as obliquely on the other side of the perpendicular abd , in the direction DA ; and the foot of his image will appear at F , in the direction of the reflected ray AD , produced to F , where it is cut by the right line BGF , drawn parallel to the right line ACE . Just the same as if the glass were taken away, and a real man stood at F , equal in size to the man standing at B : for to his eye at A , the eye of the other man at E would be seen in the direction of the line ACE ; and the foot of the man at F would be seen by the eye A , in the direction of the line ADF .

If the glass be brought nearer the man AB , as suppose to cb , he will see his image as at CDG : for the reflected ray CA (being perpendicular to the glass) will shew the eye of the image as at C ; and the incident ray Bb , being reflected in the line bA , will shew the foot of his image as at G ; the angle of reflection abA being always equal to the angle of incidence Bba : and so of all the intermediate rays from A to B . Hence, if the man AB advances towards the glass CD , his image will approach towards it; and if he recedes from the glass, his image will also recede from it.

Of the MAGIC LANTERN.

$ABCD$ (No. 31.) is a tin lantern, with a tube $nklm$ fixed in the side of it. This tube consists of two joints, one of which slips into the other: and by drawing this joint out, or pushing it in, the tube may be made longer or shorter. At kl in the end of the moveable joint of the tube a convex lens is fixed, and an object painted with transparent colours upon a piece of thin glass is placed at de somewhere in the immovable joint of the tube; so that as the tube is lengthened or shortened, the lens will be either at a greater or a less distance from this transparent object. In the side of the lantern there is a very convex lens bbc , which serves to cast a very strong light from the candle within the lantern upon the object de . Now when the rays, which shine through the object de , diverge from the several points as d , e , &c. in the object, and fall upon the lens kl , they will be made to converge to as many points f , g , &c. on the other side of the lens, and will paint an inverted picture of the

object at fg upon a white wall, a sheet or a screen of white paper, provided the object is farther from the lens than its principal focus. To make this picture appear distinct and bright, it must have no other light fall upon it but what comes through the lens kl ; and for this reason the whole apparatus is to be placed in a dark room $EFGH$. The lens kl must be very convex, so that the object de may be very near to it, and yet not be nearer than its principal focus: for by this means, as the object is near to the lens, the picture fg will be at a great distance from it, and consequently the picture will be much bigger than the object. Since the picture is inverted in respect of the object, in order to make the picture appear with the right end upwards, it is necessary that the object de should be placed with the wrong end upwards.

Of the DIFFERENT REFRACTIBILITY of LIGHT.

WE have hitherto supposed that a particle of light, as it comes from the sun, is the least particle into which light can be separated. But we must now correct this supposition, by shewing, that a particle of light, as it comes from the sun, is, properly speaking, a bundle of rays, which may be separated from one another. Therefore, for the future, by a ray of light we must be understood to mean, not that collection of particles which we have hitherto called by this name, but the least particles into which light can be separated.

Rays of light are said to be differently refrangible, when at the same or equal angles of incidence some are more turned out of the way than others.

Rays are said to be differently reflexible, if some are more easily reflected than others.

Light is called homogeneous, when all the rays are equally refrangible: it is called heterogeneous, when some rays are more refrangible than others.

The colours of homogeneous light are called primary or simple colours; and those of heterogeneous light are called secondary or mixed.

The rays of the sun are not all equally refrangible: and those rays, which have a different degree of refrangibility, have likewise a different colour.

If a beam of light SF , (No. 32.) that comes from the sun, passes into a dark room through F a round hole in a window shutter EG ; this beam proceeding straight forwards, and falling upon a paper at Y , would there make a round picture of the sun. This picture would be a confused one indeed, if the hole is a large one and there is no lens in the hole. However, as this round spot of light is a picture of the sun, we shall hereafter, notwithstanding its confusion, call it by this name. Now if a glass prism ABC is placed between the hole in the window-shutter and the paper at Y , the rays of this beam, by the refraction which they suffer in the prism, will be bent from their straight course, and instead of going on so as to fall upon the paper at Y , they will be turned upwards, and the picture of the sun produced by them will fall upon a paper MN that is placed above Y . If all the rays

5 P

+

were

were equally bent upwards, the picture would be a round one upon the paper MN, after the rays have been refracted, as well as when they passed straight forwards and fell upon a paper at Y. But this refracted picture PT is found to be oblong. The horizontal diameter or breadth of this oblong picture is equal to the diameter of the circular one Y: but the perpendicular diameter or height of the picture PT is much greater than its breadth. The refraction is made upwards, and not in a horizontal direction: therefore no alteration ought to be made in the breadth or horizontal diameter of the picture; because no refraction, that is not in the direction of that diameter, can make the picture either broader or narrower. And if all the rays were equally refracted upwards, such a refraction would not change the length of the picture; as it is round when it falls at Y, so it would be round when it is refracted upwards by the prism and falls at PT. This oblong picture consists therefore of rays, which are differently refrangible: they all fall at equal angles of obliquity upon BC the first side of the prism, but in the refraction some are more turned out of the way than others: those rays which go to P, the upper part of the picture, are the most refrangible; and those which go to T, the lower part of it, are least refrangible: the rest, which fall between P and T, have intermediate degrees of refrangibility.

This oblong picture is of different colours in different parts of it. The most refrangible rays at P are violet, the least refrangible at T are red; the rays of intermediate refrangibility from the violet downwards to the red are indigo-coloured, blue, green, yellow, and orange. So that the whole picture is made up of rays of these seven different colours. We may from hence see the reason why the coloured picture consisting of differently refrangible rays should be oblong, in such a manner that the two sides of it are right lines, and the two ends semicircles. For it consists (as in No. 33.) of seven circles, the highest of which PAGQ is violet, the lowest STN is red, the five intermediate ones, BH, CI, DK, EL, OM, are indigo coloured, blue, green, yellow, and orange. The white round picture Y, (No. 32.) is formed by heterogeneous rays, that are of seven different sorts, distinguished from one another by their different degrees of refrangibility and different colours. The refraction of the prism separates these rays from one another by refracting some of them more and others less. And consequently the refracted picture will consist of seven round pictures one below another. These round pictures are so near to each other, that the highest of them APGR will mix itself with some of those below it, as with BH and CQI. This nearness of these several round pictures to each other will prevent their colours from being distinctly seen; it will likewise make the sides AS, GN, which are composed of small arcs of circles very close to one another, appear like right lines; but the two ends P and T will be semicircles.

If the centres of these circles continue at the same distance from one another, and the circles themselves are made less, as *apq, bh, ci, dk, el, om, stn*, they will then be distinct or will not mix with each other; and as the colours of the several parts will by this means

be kept separate, so the refracted rays, instead of forming one continued oblong picture, will form seven small circular ones placed in a line perpendicular to the horizon. This separation of the several parts in the refracted picture from each other is brought about, (as in No. 34.) by making the hole F in the window-shutter very small, and by collecting the rays that come through it with a convex lens MN. For this will make a very small white picture of the sun at L, if there is no prism *abc*: but the refraction of this prism, if it is placed a little beyond the lens, will separate the heterogeneous rays by refracting them upwards; and instead of one small round and white picture at L, there will be seven small round pictures at PT, of which *r* will be violet, *x* indigo, *u* blue, *v* green, *l* yellow, *y* orange, and *z* red.

That the prism ABC (No. 32.) does not make the rays diverge, so as to spread over the space PT, upon any other account but their different refrangibility, will be evident, if (as in No. 35.) a second prism DH is placed beyond the first *abc*. For if the rays that come from S and pass through the hole F of the window shutter EG, were by the first prism *abc* made to diverge and form the oblong picture PT upon any other account besides their different refrangibility; then, supposing a second prism DH to be placed at right angles to the former, the effect must be this; the first prism *abc* makes the rays diverge from one another in a line PT perpendicular to the horizon, and consequently the second prism DH must make them diverge from one another in a line parallel to the horizon; so that the second prism would increase the breadth of the picture, as much as the first increased its length; and as one prism alone makes the picture a long one, both of them together would make it square, as *prrt*. But this second refraction does not alter the figure of the picture; but only the position of it: the second prism refracts the picture sideways; and those rays, which fell the highest at P after the first refraction, are refracted sideways the most by the second prism; those which fell the lowest at T are refracted sideways the least; by which means the picture, though it continues oblong, will not be perpendicular to the horizon as PT was, but will be inclined so as to lie in the position *prt*. This makes it evident, that the spreading of the rays by the first refraction was owing to their different refrangibility, and to no other cause. It must be owing to their different refrangibility, because those which were most refracted upwards by the first prism are most refracted sideways by the second. It cannot be owing to any other cause, because if it was, the second prism would spread the rays in breadth as much as the first prism spreads them in length, and both prisms would make the picture square.

Those rays of light, which are most refrangible, are likewise most reflexible.

When a beam of light is admitted into a dark chamber through the hole F in the window-shutter EG, (No. 36.) and this beam falls upon a prism ACB, the sides of which AC and AB are equal, and the angle at A a right one; when the obliquity of these rays, as they are to pass out of the prism at its base BC, is less than 40 degrees, the greatest part of the beam will pass out, but some few rays will

will be reflected at the surface BC. The rays, which pass through the base, form an oblong coloured picture HK, where MH is a more refrangible ray, and MK a less refrangible one. If the few rays of the beam, which are reflected from M in the direction MN, are made to pass through another prism XYV, they will likewise form an oblong coloured picture *pt*, where *p* is the most refrangible and *t* the least refrangible ray. This picture will be a very faint one, because there are but few rays reflected from M.

Now if the prism ACB is turned slowly round upon its axis in the direction ACB, the obliquity of the rays EM to the base BC will keep increasing, till at last this obliquity may become so great, that no rays will pass out at M, but all of them will be reflected. When this total reflection is made, the oblong picture *pt*, which was faint before, will become much brighter, because then not only a few rays, but all the beam, will be reflected thither. This total reflection will not be made all at once; but as the prism is turned slowly round upon its axis, the most refrangible rays MH will be first reflected, for the violet colour will disappear in the oblong picture HK, whilst all the other colours continue as bright as they were before; and when this colour disappears at HK, the same colour at *p* will become bright, and all the other colours at *pt* will continue as faint as they were before. When the prism is turned a little farther upon its axis, the indigo colour, which consists of rays that have the next greatest degree of refrangibility, will be reflected, so that this colour will disappear at HK and will become bright at *pt*. The same thing will happen to all the rays in their order; as the prism is turned round, each different sort of rays will be reflected sooner as the rays have a greater degree of refrangibility, or latter as they have a less degree. The red rays at K, which are the least refrangible of all, will be reflected last of all. From hence therefore it appears, that the rays of the sun are differently reflexible, and that those which are most refrangible are likewise most reflexible.

Homogeneous light is refracted regularly without any dilatation or scattering of the rays.

WHEN the rays of any one particular colour in the oblong picture of the sun, as the green rays, for instance, are separated from one another; if some of these green rays which are homogeneous, or are all equally refrangible, are transmitted through a very small round hole in a stiff pasteboard, and are refracted by a prism on the other side of the hole, the picture formed by these green rays after refraction upon a white paper held beyond the prism will not be oblong, but circular, as the hole is through which they passed. Therefore this homogeneous light is not dilated, nor are the rays of it scattered by this refraction.

The confused appearance of objects, when they are seen through refracting bodies, is owing to the different refrangibility of light.

If flies, or the letters of a small print, or any other minute objects, are placed in heterogeneous light, such as a direct beam of the sun's, which has never been separated by any refraction into its homogeneous parts; these ob-

jects being viewed through a glass-prism will be seen confusedly, their edges will appear so misty that the smaller parts of minute animals cannot easily be distinguished from one another, and the letters of the small print cannot be read. But if the same objects are placed in a beam of homogeneous light, which is separated from all other rays of a different refrangibility in the manner already described, they will appear as distinct through a prism as if they were viewed with the naked eye. Therefore we may conclude, that this confusion is owing to the different refrangibility of those rays which come from the objects; since objects never appear confused when they are seen through refracting bodies, unless they are enlightened with several sorts of rays which have different degrees of refrangibility.

It is probable that any single ray of the least refrangible sort contains a greater quantity of matter than any single ray of the most refrangible sort.

WE have already seen, that at the same angles of incidence violet rays will be more refracted or more turned out of the way than red rays. And we have likewise seen, that rays are refracted when they pass out of one medium into another, by being either more or less attracted in one medium than they are in the other. Now since, when all other circumstances are equal, when red rays and violet rays fall at equal obliquities, and are to pass out of glass into air, so that the mediums, and consequently the attractive force or cause of refraction, is given; if the same cause can turn the violet rays more out of the way, or refract them more, than it does the red rays, these rays must have different moments; the most refrangible rays, or those which are most easily turned out of the way, have the least moment; and the least refrangible rays, or those which are most difficult to turn out of the way, have the greatest moment. But if all sorts of rays have the same velocity, their respective quantities of matter will be as their moments; and consequently any single ray of the most refrangible sort contains a less quantity of matter than any single ray of the least refrangible sort.

It may be upon this account that a red colour, or a pale purple, is less pleasant to the eye than a blue, green, or a yellow. The red rays strike the eye with so great a force as to be offensive to it; and the small force of the pale purple ones will produce too faint a sensation to be agreeable. The intermediate colours are therefore more pleasant to the eye, as the force of the rays is neither too great to be offensive, nor too small to produce a quick and lively sensation.

The colours of homogeneous light are so invariable, that neither any refraction nor any reflection can alter them.

If a beam of homogeneous light passes through a round hole in a pasteboard, and then is refracted by a prism on the other side of the hole, this refraction will make no alteration in the colour of the rays; if they were red, or whatever was their colour, before they entered the prism, their colour will still be the same, when they have passed through it, and fall upon a white paper held beyond the prism. This proves the first part of the proposition, that the

the colours of homogeneous light are to be changed by any refraction.

Red lead, when it is viewed in open day-light, or when heterogeneous rays fall upon it, will likewise be red, if it is placed in homogeneous red light: but red lead, when it is placed in any other sort of homogeneous light, will have the same colour with the rays that fall upon it and are reflected from it: if it is placed in yellow homogeneous light, it will be yellow; if in green light, it will be green; or if in blue light, it will be blue. Consequently the reflection of the rays from the red lead make no alteration in their colour; for if it did, rays of any sort reflected from the lead would be of the same colour, so that it would appear red in whatever sort of light it was placed. The same that is here said of red lead, is true of any other substance of any other colour. Grass, which is green either in open day-light or in homogeneous green light, will not change the colour of any homogeneous rays by reflecting them, but will itself have the same colour with the rays in which it is placed; it will be red in red light, or blue in blue light, or yellow in yellow light.

From hence we may conclude, by the way, that a body is of any particular colour, not because it reflects no other rays but those of that particular colour, but because it reflects those more copiously and others more sparingly. Red lead, as it appears red in red light, so in green light it appears green, or in blue light it appears blue: consequently it reflects rays of these sorts, and in the same manner it might be shewn to reflect all other sorts of rays. But then the red colour of red lead, when it is placed in red light, is much brighter than any other colour will be that it puts on by being placed in another sort of light: consequently it reflects red rays more copiously than any other sort of rays; and for this reason, when it is placed in open day-light, where it reflects all sorts of rays at once, the red rays are so much more numerous than the rest, as to make the whole mixture of their own colour.

Colours may be produced by composition, which shall in appearance be like the colour of homogeneous light: but then these compound colours will be altered by refraction.

When, by means of two holes in the window-shutter of a dark room and of two prisms, two oblong coloured pictures are produced; if a circular piece of white paper is so placed that the red light of one picture and the yellow light of the other may fall upon it, this mixture will produce an orange colour, that in appearance will be like the primary orange colour. But between the simple and compound colour, though they are alike in appearance, there will be this difference; if the circular piece of paper, when it is enlightened with compound orange, is viewed through a prism, the rays will be found to be differently refrangible, and they will, by the refraction of the prism, be so separated from one another, that the paper seen through it will appear as two circles, one of which will be red and the other yellow; whereas, if the same paper, when it is enlightened with simple or primary orange, is viewed in like manner through a prism, the rays will be found to be equally refrangible, and the paper will appear through the prism, as it does to the naked eye, to be one

orange-coloured circle distinctly terminated all round. After the same manner other homogeneous colours, as blue and yellow, when mixed together, will produce a new compound colour like the intermediate homogeneous green colour in appearance. But then the rays of this compound green will not be all of them equally refrangible, as the rays of the simple or primary green colour are.

The whiteness of the sun's light is compounded of all the primary colours mixed in a due proportion.

Let the oblong coloured picture (No. 37.) fall upon the convex lens MN; and then all the rays which are separated from one another at PT will be collected together by passing through the lens, and will meet at its focus G, in such a manner as to form a round picture of the sun upon a white paper DE. This round picture, which consists of rays of all sorts, of red, orange, yellow, blue, green, indigo, and violet, is white. And this whiteness is compounded of all the primary colours mixed together. None of the rays change their colour by being mixed with the rest; each sort retains the same colour after it is mixed with the rest that it had before; neither the red rays, nor the orange, nor the yellow, nor the blue, nor the green, nor the indigo, nor the violet, are made white by being mixed with the rest at the focus; but though none of the parts are white, yet the whole mixture is white.

That the whiteness at the focus G arises from a mixture of all the primary colours, is evident. For if any of the colours are intercepted at the lens, the focus loses its whiteness, and becomes of that colour which arises from a mixture of those which are not intercepted. Thus if all the rays at PT are intercepted except the yellow, the orange, and the red, the focus will not be white, but will be orange-coloured. If all the rays are intercepted at PT, except the blue, the green, and the yellow, the focus will then be green. The orange in one case, and the green in the other case, is the compound colour arising from a mixture of those rays which are not intercepted. And in either case, if the rays that were intercepted are again suffered to pass through the lens, the focus will recover its whiteness.

It may be more difficult to shew that the rays, when they are all of them mixed at the focus, retain their proper colours, and are none of them white though the compound mixture is white. To make this out, let the paper be removed from DE, where all the rays are mixed upon it at G, to *de*, where it will receive the rays, after they have crossed one another at the focus, and having got beyond it diverge again. In this position of the paper, because the rays that were mixed at the focus have diverged from thence, and are again separated from one another, the oblong coloured picture will appear again at *tp*, so that the red colour T, which was the lowest at the lens, will be the highest at the paper *de*. But though the colours are thus inverted by passing the focus, yet all of them appear at *tp*; which would have been impossible, if each sort of rays, by being mixed with the rest at the focus, had lost their colour, and had been made white. Nor indeed is the colour of any sort of rays at all changed by being mixed with the rest at the focus; but the

the same rays that produced any particular colour in the oblong picture PT are the rays that produce the same colour in the inverted picture *tp*; as would be evident from intercepting any particular colour at PT: for if the green rays, for instance, are intercepted at PT, there will be no green at *tp*; or if the red are intercepted at PT, there will then appear no red colour at *tp*: and the same thing will happen upon intercepting the rays of any other colour at PT, for then that colour will vanish at *tp*.

Colours may be produced by composition that are exactly like any of the primary ones, nor fully white.

If the red rays of one coloured picture are mixed with the violet rays of another, according to the various proportions in which they are mixed, various purples will be produced, such as are not like in appearance to the colour of any homogeneous light; and of these purples, mixed with yellow and blue, may be made other new colours.

By mixing the coloured powders which painters use, though the powders themselves resemble the primary colours, yet the mixture may be grey, or dun, or russet-brown, such as are the colours of a man's nail, of a mouse, of ashes, of ordinary stones, of mortar, of dust and dirt in the high-ways. Thus one part of red lead, and five of viride æris, compose a dun colour like that of a mouse. If to orpiment, which is yellow, a full bright purple powder used by painters is added, the mixture may be made of a pale red; and with the addition of a little viride æris, which, as the name imports, is green, and of a little blue life, this pale red will change to grey or pale white, such as is the colour of ashes, or of wood newly cut, or of a man's skin.

These grey, dun, and russet colours are only imperfect sorts of white. And we may understand, why the mixture of these coloured powders should produce an imperfect white, and not a full bright one, from the following observation. All coloured powders suppress and stop great part of the light that falls upon them: they reflect more of those rays from whence their colour arises than of any other sort; but they reflect even those more sparingly than white bodies do. Red lead, for instance, reflects fewer red rays than white paper does; for if red lead and white paper are both of them placed in homogeneous red light, the paper will appear of a brighter red than the lead. But if red lead suppresses many red rays, it may well be supposed to suppress many more rays of other colours; since its redness is owing to its reflecting red rays more copiously, and all other rays more sparingly. From hence it follows, that in a mixture of coloured powders, though they reflect rays of all sorts in a due proportion, so that the compound light will not be more of one colour than another, but will be white; yet the whiteness will be much less bright than that of paper; because the mixture of powders suppresses and stops many rays, whereas the paper reflects almost all the rays that fall upon it, and suppresses scarce any. Thus the whiteness in the mixture of powders, and the whiteness in the paper, are both of the same sort, and differ from one another only in degree, or in the quantity of light. Therefore, if some of this mixture of powders is placed in bright sunshine, and a piece of white paper is placed in the shade, the mixture by thus

increasing the light, and the paper by thus diminishing it, may be made to appear equally white.

The colours of all bodies are either the simple colours of homogeneous light, or such compound colours as arise from a mixture of homogeneous light.

EACH sort of light has a peculiar colour of its own, which no refraction or reflection can change. Therefore the colour of no natural body can be any other than either the colour of some sort of homogeneous light, or a compound colour arising from a mixture of the several sorts. For bodies appear coloured only by reflecting light; and no reflection can give any other colours to the rays but what they had before.

Of the COLOURS of THIN TRANSPARENT PLATES.

Water, air, glass, or any other transparent substance, when drawn out into thin plates, become coloured.

WATER, when it is made tenacious by having soap mixed with it, may be blown up into a bubble A, (No. 38.) such as children play with. If this bubble is set under a glass, so that the motion of the air may not affect it, then as the water glides down the sides of it, and the top of it at A grows thinner, several colours will successively appear at A, and will spread themselves from thence in rings surrounding A, and descending farther and farther down the sides of the bubble, till they vanish at BC in the same order in which they appeared. Thus, for instance, the first colour that appears at A, the top of the bubble, is red: this red spot spreads itself into a circular ring round A, and then the top of the bubble A becomes blue: this blue spot spreads itself in the same manner round A, and then A becomes red a second time. Before we go on to consider what other colours arise at A, we will observe what becomes of those which arise first. The red, which first appeared at A, spreads itself into a circular ring round A: this ring grows larger, as the water glides down the sides of the bubble; so that the coloured ring glides down the bubble along with the water, till it sinks at last to BC, and there encompasses the bubble. In like manner the blue, which arises at A after the red, spreads itself and descends down the bubble, as the red ring did. The colour which arises next at A, is red a second time; this spreads itself in the same manner, and is succeeded by blue a second time. These are followed by a great variety of colours, which appear successively at A, and spread themselves from thence in this order: Red, yellow, green, blue, purple; then again red, yellow, green, blue, violet; and lastly, red, yellow, white, blue. This last blue colour is succeeded at A by a black spot, which reflects scarce any light: this spot dilates itself, but not into a circular ring as the colours had done; it becomes broader and broader, till the bubble breaks.

A thin plate of water of the same sort with this bubble, but more lasting, may be otherwise procured. If a piece of plane polished glass is placed upon the object-glass of a long telescope, as in (No. 39.) the plane surface of one glass, and the convex one of the other, will touch one another only at a single point; and if the interval between them is filled with water, as the glasses are pressed together, the same colours arise at the point of

contact, and spread themselves in circular rings round it in the same order as in the soap-bubble. If BC (No. 40.) is a section of the plane glass, and DAE a section of the convex one; when they are pressed close together, the thin plate of water that fills the interval between them will have a black spot at A; and this spot will be encompassed with rings of colours, in the same order that they stand in that figure upon the line BC, on each side of A. If the colours are reckoned in the order in which they stand on the plate of water after the black spot appears at A, and we reckon them from the spot A towards the edges of the plate at B and C; then we must call blue the first colour. But if we reckon them in the order in which they arose at A, and spread themselves; then we must begin from B or C, the edges of the plate, and go on towards A, and in this reckoning we must call red the first colour.

If there is no water between the two glasses, then the interval will be filled with air, and this thin plate of air will have the same colours that the plate of water had; with this difference only, that each of the coloured rings is larger in the plate of air than in the plate of water.

When glass is blown very thin at a lamp-furnace, thin plates of it thus formed will exhibit colours; and so likewise will thin plates of Muscovy-glass. Metals, when they are heated, send out to their surfaces scoria or vitrified parts, which cover the metals in form of a thin skin; and these scoria or thin plates cause colours upon the surface of the metal, such as are made to appear on polished steel by heating it, or on bell-metal by melting it soft and then pouring it on the ground to cool in the air.

When the thin plate is denser than the medium that surrounds it, the colours are more vivid than they are when the plate is rarer than that medium.

A thin bubble is a plate of water encompassed with air; where the substance of the plate, which is water, is denser than the air, which is the medium that surrounds it. On the contrary, the plate of air between the two glasses BAC, DAE, (No. 40.) is encompassed with glass; and here the substance of the plate is rarer than that of the circumambient medium; and the colours on the bubble of water are more vivid than those on the thin plate of air.

When thin transparent plates reflect one sort of rays, they transmit the rest.

If the plate of air between the two glasses BAC, DAE, (No. 40.) is viewed by reflected light, the colours of it are those expressed on the upper part of the figure from B to C; but if we look through it, that is, if we view it by transmitted light, or if the transmitted light falls upon a white paper, the colours that we see through the plate, or that fall on the paper, are those expressed on the lower part of the figure. Now, any of the transmitted colours are what would arise from a mixture of all the remaining rays, after those of the reflected colour are separated from the sun's heterogeneous light. Thus, for instance, the fourth reflected colour from the black spot A inclusively is yellow, the transmitted colour is violet. The yellow rays, and some of the orange and green, are reflected here, so that the mixture of the reflected light will be yellow. The mixture of the transmitted light therefore will be violet, or

rather such a purple as is not exactly like any of the primary colours; for we observed, that from red rays, violet, and blue, new purples may be produced.

This is the case in some natural bodies, as well as in these transparent artificial plates; for if leaf-gold, which is made thin enough to transmit light, is held against the strong light of the sun's rays, the gold, which is yellow when seen by the reflected light, will be blue when thus seen by transmitted light.

The seventh reflected colour inclusively from the black spot is blue, the seventh transmitted colour is yellow. When the rays which make the blue colour are taken out of the sun's heterogeneous light, the remaining rays will be yellow. Thus it happens likewise in some natural bodies; for an infusion of lignum nephriticum, which is blue when seen by reflected light, is yellow when seen by transmitted light.

The black spot A reflects scarce any light: and as rays of all colours are transmitted there, the transmitted colour is white; the third reflected colour from the black spot inclusively is white. Therefore, since all the rays are reflected there, no colour ought to be seen there, when we look through the plate; and accordingly that part of the plate is black.

Hence we see the reason why, if there be two liquors of full colours in two different glass vessels, suppose red and blue; though each is transparent when we look thro' it separately, yet we should not be able to see through both of them together if one was held behind the other. For if the blue liquor, for instance, is held towards the light, and the red towards the eye; since only blue rays pass through the first liquor, and come to the second; and since the second liquor will transmit no blue rays, but only red ones; it follows, that no rays at all can come to the eye.

Indeed some transparent bodies appear of the same colour, whether we see them by reflected or transmitted light. Of this sort is most painted glass. But when this is the case, the coloured rays are reflected from the second surface of the body. Thus, if a piece of painted glass is yellow either when seen by reflected light or when seen by transmitted light, all the rays but the yellow ones are suppressed as they pass through the glass: of the yellow rays, most are transmitted at the second surface; the few which are reflected from thence will be sufficient to tinge all the light yellow, which is reflected from the first surface. This will be evident from making the body thick, and pitching it on the backside: for by this means the reflected colour will be lost; whereas, if it had been reflected from the first surface, the pitch at the second surface could not have altered it.

The more dense the substance is out of which a thin plate is made, the less is the thickness of the plate where it reflects any certain colour.

The colours are the same whether there is air or water between the two glasses BAC, DAE, (No. 40.) only the coloured circles are smaller in the plate of water than in the plate of air. Thus the yellow, for instance, which is the fourth coloured circle from the black spot, is a less circle, or is nearer to the black spot, when there is a plate of water between the glasses, than when there is a plate

plate of air between them. But the less the distance from the point of contact A, the closer the glasses are to one another, and consequently the thinner will be the plate that lies between them; consequently that part of a plate of water where this yellow appears, is thinner than that part of a plate of water where the same colour appears. And the same holds good in any other colour. But water is more dense than air: therefore, the more dense the substance is out of which a thin plate is made, the less is the thickness of the plate where it reflects any certain colour.

The sort of colour, which is reflected from any part of a thin plate, depends only upon the thickness of the plate itself in that part: but the same colour will be made less vivid by increasing the density of the medium with which the plate is encompassed.

The colours upon any part of a thin plate of Muscovy glass are the same in sort, whether the plate is dry or wetted with water. Therefore the sort of colour in any part depends not upon the medium that encompasses the plate, but upon the thickness of the plate itself; since the colours are the same when the plate is dry and encompassed with air, or wet and so encompassed with water. But the same colours are more faint when the plate is wet, than when it is dry; and consequently, the brightness of the colours does depend upon the medium that encompasses the plate; and the denser that medium is, the fainter will be the colours; they are more faint when the plate is covered with water than when it is dry and so is surrounded with air.

The rays of light have alternate fits of easy reflection and easy transmission, which return at equal intervals.

Let GF, (No. 41.) be a beam of homogeneous light consisting all of one sort of rays, as suppose all the rays that compose the beam were red ones. Then, if these rays fall upon a thin plate of air between the two glasses BAC, DAE, at A there will be a dark spot, and all the rays will be transmitted: round this spot there will be a red ring, where all the rays are reflected; round this red ring there will be a dark ring, where all the rays are transmitted. And if the thickness of the plate where all the rays are reflected in the ring nearest to A is called 1, the thickness where the dark ring appears and all the rays are transmitted will be 2. Again, at that part of the plate where the thickness is 3, all the rays will be transmitted: at the thickness 4, they will be all reflected. And thus alternately, as expressed by the lines in the figure, the rays will be reflected in all parts of the plate where the thickness is expressed by any of the uneven numbers 1, 3, 5, 7, 9, &c. and will be transmitted where the thickness is expressed by any of the even numbers 2, 4, 6, 8, 10, &c.

Now as the plate is the same in all parts, the cause of this alternate reflection and transmission must be in the rays themselves; and their dispositions to be thus alternately reflected and transmitted, are what we call fits of easy reflection and easy transmission.

The rays that are in a fit of easy reflection penetrate as far as the second surface of the plate. For if the se-

cond surface of a thin plate of Muscovy glass is wetted, the colours caused by the alternate reflection grow fainter; whereas if the reflection was made at the first surface, wetting the second could not affect the colours. But since those rays which have passed from the first surface of the plate to the second where the thickness of it is 1, are reflected, and those which have passed from the first surface to the second where the thickness of it is 2, are transmitted; and then again those which have thus passed from one surface to the other, where the thickness is 3, are reflected; and those which have passed in the same manner, where the thickness is 4, are transmitted; it follows, that the fits of easy reflection and transmission return at equal intervals. So that, if a ray was to set out from A in the line AB, (No. 42.) and was to be in a fit of easy reflection when it had moved from A to c, it would be in a fit of easy transmission when it had moved to twice that distance from A, or when it was got to d: at e, or the distance 3 from A, it will be in a fit of easy reflection; at f, or the distance 4, in a fit of easy transmission; at g, or 5, in a fit of easy reflection; at B, or 6, in a fit of easy transmission: and thus, in the farther progress of the ray, the same fits will return at equal intervals.

Thus if the thickness of the plate of air, where the rays of any homogeneous colour are all reflected, is equal to Ac or 1, and the rays are in a fit of easy reflection when they come to the second surface of the plate; then, where the thickness of the plate is Ad or 2, the rays will be in a fit of easy transmission when they come to the second surface, and consequently will all pass through that surface. Again, where the thickness is Ae or 3, the rays, when they come to the second surface, will be in a fit of easy reflection, and will all be reflected; where the thickness is Af or 4, the fit of easy transmission will be returned when the rays come to the second surface, so that all of them will be transmitted. And in like manner, by such fits returning at equal intervals, the rays will be reflected where the thickness is expressed by the number 1, 3, 5, 7, 9, &c. and will be transmitted where it is expressed by 2, 4, 6, 8, 10, &c.

When a thin coloured plate is viewed obliquely, the colours of every part in the plate will be altered.

When a bubble of water or a plate of air between two glasses BAC, DAE, (No. 40.) is viewed obliquely, the coloured rings dilate themselves: and consequently a ring of any one colour, by being dilated, gets into that part of the plate where a ring of some other colour appeared when the plate was viewed directly.

If the plate is denser than the medium that encompasses it, the colours of it, when viewed obliquely, change less than they would if the plate was rarer than the medium that encompasses it.

A bubble of water is a thin plate denser than the air that encompasses it: and a plate of air between the two glasses BAC, DAE, (No. 48.) is rarer than the glass that encompasses it. Upon viewing each of these thin plates obliquely, the coloured rings on the plate of water dilate less than those on the plate of air. Therefore, since it is by this dilation of the rings that a ring of

one colour goes into a part of the plate where a ring of some other colour appeared when the plate was viewed directly; that is, since it is by this dilatation of the rings that the several parts of the plates change their colours; it follows, that any part of a plate of water encompassed with air changes colour less upon being viewed obliquely, than any part of a plate of air encompassed with glass.

When the medium which encompasses a coloured transparent plate is given, the colours change less upon altering the situation of the eye, as the substance is more dense out of which that plate is made.

The matter out of which a bubble of water is made is not so dense as that out of which a bubble of glass is made, and glass is not so dense as the scoria or glassy skin thrown out by metals when they are heated. Now, any of these plates either of water, or glass, or metal-line substance, when they are encompassed with the same medium air, will change their colour a little upon being viewed obliquely; but the plate of water changes the most, the plate of glass less than that, and the scoria of metals least of all.

Of the Opakeness, Transparency, and Colours of NATURAL BODIES.

The opakeness of bodies is owing to the many reflections and refractions which the rays of light suffer within those bodies.

THE smallest parts of almost all natural bodies are transparent, as will readily be granted by those who have been used to look through microscopes. A piece of leaf-gold is transparent if it is held up against the hole of a window-shutter in a dark room; and any other substance, however opaque it may seem in the open air, will appear transparent by the same means, when it is made of a sufficient thinness. Even metals become transparent, if they are dissolved in a proper menstruum, as gold in aqua regia, or silver in aqua fortis; and by being thus dissolved, are reduced to very small particles. But since even in opaque bodies every single particle transmits light, or is transparent, the whole would likewise transmit light, unless the rays, when they are to pass through all the particles which make up the whole, were so turned out of the way by innumerable refractions and reflections, as to be stopped and suppressed in their passage. That this is the reason why bodies that consist of transparent particles should be opaque, is evident; since opaque bodies, when they are reduced to a sufficient thinness, become transparent: for then there will be but few particles lying beyond one another for the light to pass through; and as the rays will suffer fewer refractions and reflections, some of them may get through a thin plate, though all of them would be suppressed in a thicker mass of the same substance.

The medium, with which the pores of opaque bodies are filled, is not of the same density with the particles of those bodies.

BODIES consist of transparent particles, and their opakeness is owing to the many reflections and refractions which the light suffers within them. Now, if the interstices between the particles of any body were filled with

a medium of the same density with the particles, the light would neither be refracted nor reflected as it passed out of the particles into the interstices and out of the interstices into the pores, but would pass through the body, and the body would be transparent. Consequently, in an opaque body, where the light is suppressed by the refractions and reflections which it suffers, the particles that compose the body, and the medium that fills the pores or interstices between the particles, must be of different densities.

Hence we may see the reason why paper, when it has been dipped in water or oil, is more transparent than when it is dry. For when the paper is thoroughly wetted with water or oil, the pores of it are filled with a medium that is nearly of the same density with its particles. On the contrary, though oil of turpentine and water are both of them transparent when they are separate; yet if they are shaken together so as to mix but imperfectly, the mixture becomes much less transparent; because the parts of each fluid are separated from one another, and those of the other fluid, which are of a different density, get in between them.

The parts of bodies, and their interstices, must not be less than of a certain definite bigness to render them opaque and coloured.

THE most opaque bodies become transparent when their particles are subtly divided; as metals, such as gold or silver, which are opaque in large masses, become transparent when the former is dissolved in aqua regia, and the latter in aqua fortis. And we observed, that at the top of a bubble of water, where the water is extremely thin, there is a black spot, which reflects scarce any light at all; though the water is encompassed with air, which is a medium of a different density. Consequently, if the diameter of the particles of which any natural substance consists was no greater than the thickness of the bubble, where it reflects no light, but transmits all, such a body would be transparent, notwithstanding the interstices that are between its particles were filled with a medium the density of which is different from theirs.

In like manner, we observed, that when a thin plate of air lies between two pieces of glass BAC, DAE, (No 40.) there is a dark spot, which reflects no light, and transmits all, not only at the point A where the glasses touch one another, but also round that point to some distance where the glasses are very near to one another. From hence we may conclude, that though the particles of any natural substance were as dense as glass, and the medium which fills their interstices was as rare as air; yet if these interstices were no bigger than the interval between the two glasses BAC, DAE, at that place where all light is transmitted, such a body would be transparent.

The transparency of water seems to be owing to the causes here mentioned, to the smallness of its parts, or of its pores, or of both. For we are sure that the pores of water are filled with air, because the air may be drawn out from the water in an air-pump; and consequently, as the pores are filled with a medium of a different density from the parts, the mixture ought to be opaque, like such a mixture of water and oil of turpentine as was mentioned above. But the smallness either of the parts,

or of the interstices, or of both, will prevent the mixture from being opaque.

Since therefore all bodies will be transparent, if either their parts or their interstices are too small, it follows that the parts, and likewise the pores, of such bodies as are not transparent but opaque and coloured, must not be less than of a certain and determinate bigness.

The colours of natural bodies depend upon the size of their particles.

DIFFERENT parts of thin transparent plates, according to the different thickness of them, are of different colours. Now if any part of such a thin plate of glass, for instance, where it appears of one uniform colour, should be split into threads, or broken into small particles, all these particles would make a heap of powder of the same colour. And the small particles of natural bodies, since they are transparent, like so many fragments of a thin plate, must exhibit colours in the same manner.

The parts of bodies, on which their colours depend, are much denser than the medium which fills their pores.

FOR where the transparent plate or particle consists of a rarer substance than the medium that encompasses it, the colours are less vivid than those of natural bodies commonly are. For this reason it is that the colours of silks or cloths, when they are wetted with oil or water, become more faint; because these liquors are more nearly of the same density with the particles, than the medium is which fills the interstices when they are dry. Besides, the colours upon a transparent plate change very sensibly, unless the plate consists of a substance much denser than the medium that encompasses it; but most natural bodies are of the same colour in whatever position of the eye they are viewed. Therefore their transparent particles, upon which their colours depend, are much denser than the medium which encompasses those particles or fills the interstices between them.

Nor is the case otherwise even in those bodies which do change colour upon being viewed obliquely, such as changeable silks, or the feathers of a peacock's tail or of a pigeon's neck. For this change of colour, upon the situation of the eye being changed, is no reason for concluding that the medium which fills the interstices or pores is more nearly of the same density with the particles, upon which the colours depend, in these bodies than in others; since the change of colour is plainly owing to our seeing a different part of the body in different positions of the eye. Thus, in changeable silks, the warp is of one colour, and the woof of another; and in one position of the eye more of the warp is seen, and in another position it is more of the woof is seen. In like manner, if a pigeon's neck appears blue in one position of the eye, and crimson in another, it is because in these different positions we see different parts of the same feathers.

We cannot from the colour of a body make any conjecture about the size of the particles upon which its colours depend.

SUPPOSE, from the appearance of the colour in any yellow body, that we had determined its yellow to be of the same sort with that which is next to the black spot

in a plate of air, or water, or glass. The thickness of a plate, where it appears of this colour, is different according to the different density of the substance out of which that plate is made; the thickness of a plate of air where it appears of this colour, is greater than that of a plate of water where it appears of the same colour, and much greater still than that of a plate of glass. Suppose therefore farther, that we were able to determine exactly what is the thickness of a plate of air or water or glass, where each of them is tinged with the same yellow colour that any natural body exhibits; yet we cannot determine whether the diameter of the particles, upon which this body's colour depends, is equal to the thickness of the plate of air, or of water, or of glass, unless we could first determine whether the density of those particles is equal to the density of air, or to that of water, or to that of glass: since the particles must be larger, if their density is equal to the density of air, than if it is equal to the density of water; and larger, if it is equal to that of water than if it is equal to that of glass. And indeed we have good reason to conclude, that the density of the parts, upon which the colours of natural bodies depend, is greater even than that of glass; and consequently that the diameter of those parts is much less than the thickness of a plate of glass, where it appears of the same colour with the body. For, upon being viewed obliquely, thin plates of glass change colour, whereas natural bodies do not: and the colour of natural bodies is made more unchangeable than of thin plates of glass, by their particles being more dense than glass.

Of the RAINBOW.

When the rays of the sun fall upon a drop of rain and enter into it, some of them, after one reflection and two refractions, may come to the eye of a spectator who has his back towards the sun and his face toward the drop.

IF XY (No. 43.) is a drop of rain, and the sun shines upon it in any lines *sf, sd, sa*, &c. most of the rays will enter into the drop: some few of them only will be reflected from the first surface; those rays, which are reflected from thence, do not come under our present consideration, because they are never refracted at all. The greatest part of the rays then enter the drop, and those passing on to the second surface will most of them be transmitted through the drop; but neither do those rays which are thus transmitted fall under our present consideration, since they are not reflected. For the rays, which are described in the proposition, are such as are twice refracted and once reflected. However, at the second surface, or hinder part of the drop, at *pg* some few rays will be reflected, whilst the rays are transmitted: those rays proceed in some such lines as *nr, nq*; and coming out of the drop in the lines *ro, qt*, may fall upon the eye of a spectator, who is placed any where in those lines, with his face towards the drop, and consequently with his back towards the sun, which is supposed to shine upon the drop in the lines *sf, sd, sa*, &c. These rays are twice refracted, and once reflected: they are refracted, when they pass out of the air into the drop; they are reflected from the second surface, and are refracted again, when they pass out of the drop into the air.

When rays of light reflected from a drop of rain come to the eye, those are called effectual which are able to excite a sensation.

When rays of light come out of a drop of rain, they will not be effectual, unless they are parallel and contiguous.

THERE are but few rays that can come to the eye at all: for the greatest part of those rays which enter the drop xy (No. 43.) between x and a , pass out of the drop thro' the hinder surface pg ; only few are reflected from thence and come out through the nearer surface between a and y . Now such rays as emerge, or come out of the drop, between a and y , will be ineffectual, unless they are parallel to one another, as rv and qt are; because such rays as come out diverging from one another, will be so far asunder when they come to the eye, that all of them cannot enter the pupil; and the very few that can enter it will not be sufficient to excite any sensation. But even rays, which are parallel, as rv, qt , will not be effectual, unless there are several of them contiguous or very near to one another. The two rays rv and qt alone will not be perceived, though both of them enter the eye; for so very few rays are not sufficient to excite a sensation.

When rays of light come out of a drop of rain after one reflection, those will be effectual which are reflected from the same point, and which entered the drop near to one another.

ANY rays, as sb and cd , (No. 44.) when they have passed out of the air into a drop of water, will be refracted towards the perpendiculars bl, dl ; and as the ray sb falls farther from the axis av than the ray cd , sb will be more refracted than cd ; so that these rays, though parallel to one another at their incidence, may describe the lines be and de after refraction, and be both of them reflected from one and the same point e . Now all rays which are thus reflected from one and the same point, when they have described the lines ef, eg , and after reflection emerge at f and g , will be so refracted, when they pass out of the drop into the air, as to describe the lines fb, gf , parallel to one another. If these rays were to return from e in the lines eb, ed , and were to emerge at b and d , they would be refracted into the lines of their incidence bs, ds . But if these rays, instead of being returned in the lines eb, ed , are reflected from the same point e in the lines eg, ef , the lines of reflection eg and ef will be inclined both to one another and to the surface of the drop: just as much as the lines eb and ed are. First eb and eg make just the same angle with the surface of the drop: for the angle bex , which eb makes with the surface of the drop, is the complement of incidence; and the angle gey , which eg makes with the surface, is the complement of reflection; and these two are equal to one another. In the same manner we might prove that ed and ef make equal angles with the surface of the drop. Secondly, the angle bed is equal to the angle seg , or the reflected rays eg, ef , and the incident rays be, de , are equally inclined to each other. For the angle of incidence bel is equal to the angle of reflection gel , and the angle of incidence del is equal to the angle of reflection

fel ; consequently the difference between the angles of incidence is equal to the difference between the angles of reflection, or $bel-del=gel-fel$, or $bed=gef$. Since therefore either the lines eg, ef , or the lines eb, ed , are equally inclined both to one another and to the surface of the drop; the rays will be refracted in the same manner, whether they were to return in the lines eb, ed , or are reflected in the lines eg, ef . But if they were to return in the lines eb, ed , the refraction, when they emerge at b and d , would make them parallel. Therefore, if they are reflected from one and the same point e in the lines eg, ef , the refraction, when they emerge at g and f , will likewise make them parallel.

But though such rays, as are reflected from the same point in the hinder part of a drop of rain, are parallel to one another, when they emerge, and so have one condition that is requisite towards making them effectual; yet there is another condition necessary; for rays, that are effectual, must be contiguous, as well as parallel. And though rays, which enter the drop in different places, may be parallel when they emerge, those only will be contiguous which enter it nearly at the same place.

Let xy , (No. 43.) be a drop of rain, ag the axis or diameter of the drop, and sa a ray of light that comes from the sun and enters the drop at the point a . This ray sa , because it is perpendicular to both the surfaces, will pass straight through the drop in the line agb without being refracted; but any collateral rays that fall about sb , as they pass through the drop, will be made to converge to their axis, and passing out at n will meet the axis at b : rays which fall farther from the axis than sb , such as those which fall about sc , will likewise be made to converge; but then their focus will be nearer to the drop than b . Suppose therefore i to be the focus to which the rays that fall about sc will converge, any ray sc , when it has described the line co within the drop, and is tending to the focus i , will pass out of the drop at the point o . The rays that fall upon the drop about sd , more remote still from the axis, will converge to a focus still nearer than i , as suppose at k . These rays therefore go out of the drop at p . The rays, that fall still more remote from the axis, as se , will converge to a focus nearer than k , as suppose at l ; and the ray se , when it has described the line eo within the drop, and is tending to l , will pass out at the point o . The rays, that fall still more remote from the axis, will converge to a focus still nearer. Thus the ray sf will after refraction converge to a focus at m , which is nearer than l ; and having described the line fn within the drop, it will pass out at the point n . Now here we may observe, that as any rays sb or sc , fall farther above the axis sa , the points n , or o , where they pass out behind the drop, will be farther above g ; or that, as the incident ray rises from the axis sa , the arc gno increases, till we come to some ray sd , which passes out of the drop at p ; and this is the highest point where any ray that falls upon the quadrant or quarter ax can pass out: for any rays se , or sf , that fall higher than sd , will not pass out in any point above p , but at the points o , or n , which are below it. Consequently, though the arc $gnop$ increases, whilst the distance of the incident ray from the axis sa increased, till we came to the ray sd ; yet afterwards, the higher the

ray falls above the axis sa , this arc $pong$ will decrease. We have hitherto spoken of the points on the hinder part of the drop, where the rays pass out of it; but this was for the sake of determining the points from whence those rays are reflected, which do not pass out behind the drop. For, in explaining the rain-bow, we have no farther reason to consider those rays which go through the drop; since they can never come to the eye of a spectator placed any where in the lines rv or qt with his face towards the drop. Now, as there are many rays which pass out of the drop between g and p , so some few rays will be reflected from thence; and consequently the several points between g and p , which are the points where some of the rays pass out of the drop, are likewise the points of reflection for the rest which do not pass out. Therefore, in respect of those rays which are reflected, we may call gp the arc of reflection; and may say, that this arc of reflection increases, as the distance of the incident ray from the axis sa increases, till we come to the ray sd ; the arc of reflection is gn for the ray sb , it is go for the ray sc , and gp for the ray sd . But after this, as the distance of the incident ray from the axis sa increases, the arc of reflection decreases; for og less than pg is the arc of reflection for the ray se , and ng is the arc of reflection for the ray sf .

From hence it is obvious, that some one ray, which falls above sd , may be reflected from the same point with some other ray which falls below sd . Thus, for instance, the ray sb will be reflected from the point n , and the ray sf will be reflected from the same point; and consequently, when the reflected rays nr , ng , are refracted as they pass out of the drop at r and g , they will be parallel, by what has been shewn in the former part of this proposition. But since the intermediate rays, which enter the drop between sf and sb , are not reflected from the same point n , these two rays alone will be parallel to one another when they come out of the drop, and the intermediate rays will not be parallel to them. And consequently these rays rv , qt , though they are parallel after they emerge at r and g , will not be contiguous, and for that reason will not be effectual; the ray sd is reflected from p , which has been shewn to be the limit of the arc of reflection; such rays, as fall just above sd , and just below sd , will be reflected from nearly the same point p , as appears from what has been already shewn. These rays therefore will be parallel, because they are reflected from the same point p ; and they will likewise be contiguous, because they all of them enter the drop at one and the same place very near to d . Consequently, such rays as enter the drop at d , and are reflected from p the limit of the arc of reflection, will be effectual; since, when they emerge at the fore part of the drop between a and j , they will be both parallel and contiguous.

If we can make out hereafter that the rain bow is produced by the rays of the sun which are thus reflected from drops of rain as they fall whilst the sun shines upon them, this proposition may serve to shew us, that this appearance is not produced by any rays that fall upon any part and are reflected from any part of those drops: since this appearance cannot be produced by any rays but those which are effectual; and effectual rays must al-

ways enter each drop at one certain place in the fore-part of it, and must likewise be reflected from one certain place in the hinder surface.

When rays that are effectual emerge from a drop of rain after one reflection and two refractions, those which are most refrangible will, at their emergence, make a less angle with the incident rays than those do which are least refrangible; and by this means the rays of different colours will be separated from one another,

Let sh and gi , (No. 44.) be effectual violet rays emerging from the drop at g ; and sn , gp , effectual red rays emerging from the same drop at the same place. Now, though all the violet rays are parallel to one another, because they are supposed effectual; and though all the red rays are likewise parallel to one another for the same reason; yet the violet rays will not be parallel to the red rays. These rays, as they have different colours, and different degrees of refrangibility, will diverge from one another; any violet ray gi , which emerges at g , will diverge from any red ray gp , which emerges at the same place. Now, both the violet ray gi , and the red ray gp , as they pass out of the drop of water into the air, will be refracted from the perpendicular lo . But the violet ray is more refrangible than the red one, and for that reason gi , or the refracted violet ray, will make a greater angle with the perpendicular than gp the refracted red ray; or the angle igo will be greater than the angle pgo . Suppose the incident ray sb to be continued in the direction sk , and the violet ray ig to be continued backward in the direction ik , till it meets the incident ray at k . Suppose likewise the red ray pg to be continued backwards in the same manner, till it meets the incident ray at w . The angle ikk is that which the violet ray, or most refrangible ray at its emergence, makes with the incident ray; and the angle pww is that which the red ray, or least refrangible ray at its emergence, makes with the incident ray. The angle ikk is less than the angle pww . For, in the triangle gwk , gws or pws is the external angle at the base, and gkw or iks is one of the internal opposite angles; and either internal opposite angle is less than the external angle at the base. Euc. b. I. prop. 16. What has been shewn to be true of the rays gi and gp might be shewn in the same manner of the rays sh and sn , or of any other rays that emerge respectively parallel to gi and gp . But all the effectual violet rays are parallel to gi , and all the effectual red rays are parallel to gp . Therefore the effectual violet rays at their emergence make a less angle with the incident ones than the effectual red ones. And for the same reason, in all the other sorts of rays, those which are most refrangible, at their emergence from a drop of rain after one reflection, will make a less angle with the incident rays, than those do which are less refrangible.

Or otherwise: When the rays gi and gp emerge at the same point g , as they both come out of water into air, and consequently are refracted from a perpendicular, instead of going straight forwards in the line eg continued, they will both be turned round upon the point g from the perpendicular go . Now it is easy to conceive, that either of these lines might be turned in this manner upon the point

g as upon a centre, till they became parallel to *sb* the incident ray. But if either of these lines or rays were refracted so much from *go* as to become parallel to *sb*, the ray so much refracted would, after emergence, make no angle with *sk*, because it would be parallel to it. And consequently that ray which is most turned round upon the point *g*, or that ray which is most refrangible, will after emergence be nearest parallel to the incident ray, or will make the least angle with it. The same may be proved of all other rays emerging parallel to *gi* and *gp* respectively, or of all effectual rays; those, which are most refrangible, will after emergence make a less angle with the incident rays, than those do which are least refrangible.

But since the effectual rays of different colours make different angles with *sk* at their emergence, they will be separated from one another: so that if the eye was placed in the beam *feh*, it would receive only rays of one colour from the drop *xog*; and if it was placed in the beam *fgnp*, it would receive only rays of some other colour.

The angle *rup*, which the least refrangible or red rays make with the incident ones, when they emerge so as to be effectual, is found by calculation to be 42 degrees 2 minutes. And the angle *ski*, which the most refrangible rays make with the incident ones, when they emerge so as to be effectual, is found to be 40 degrees 17 minutes. The rays, which have the intermediate degrees of refrangibility, make with the incident ones intermediate angles between 42 degrees 2 minutes and 40 degrees 17 minutes.

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator, the angle which any effectual ray, after two refractions and one reflection, makes with the incident ray, will be equal to the angle which it makes with that line.

Let the eye of the spectator be at *i*, (No. 44.) and let *gt* be the line supposed to be drawn from the centre of the sun through the eye of the spectator; the angle *git*, which any effectual ray makes with this line, will be equal to the angle *iks*, which the same ray makes with the incident ray *sb* or *sk*. If *sb* is a ray coming from the centre of the sun, then since *gt* is supposed to be drawn from the same point, these two lines, upon account of the remoteness of the point from whence they are drawn, may be looked upon as parallel to one another. But the right line *ki* crossing these two parallel lines will make the alternate angles equal. Euc. b. I. prop. 29. Therefore *kit* or *git* is equal to *ski*.

When the sun shines upon the drops of rain as they are falling; the rays that come from those drops to the eye of a spectator, after one reflection and two refractions, produce the primary rainbow.

If the sun shines upon the rain as it falls, there are commonly seen two bows, as AFB, CHD, (No. 46.) or if the cloud and rain does not reach over that whole side of the sky where the bows appear, then only a part of one or of both bows is seen in that place where the rain falls. Of these two bows, the innermost AFB is the more vivid of the two, and this is called the primary bow. The outer part TEF of the primary bow is red, the inner part

VEH is violet; the intermediate parts, reckoning from the red to the violet, are orange, yellow, green, blue, and indigo. Suppose the spectator's eye to be at *O*, and let LOP be an imaginary line drawn from the centre of the sun through the eye of the spectator: If a beam of light *S* coming from the sun falls upon any drop *F*; and the rays that emerge at *F* in the line FO, so as to be effectual, make an angle FOP of 42 degrees 2 minutes with the line LP; then these effectual rays make an angle of 42 degrees 2 minutes with the incident rays, by the preceding proposition, and consequently these rays will be red, so that the drop *F* will appear red. All the other rays, which emerge at *F*, and would be effectual if they fell upon the eye, are refracted more than the red ones, and consequently will pass above the eye. If a beam of light *S* falls upon the drop *E*; and the rays that emerge at *E* in the line EO, so as to be effectual, make an angle EOP of 40 degrees 17 minutes with the line LP; then these effectual rays make likewise an angle of 40 degrees 17 minutes with the incident rays, and the drop *E* will appear of a violet colour. All the other rays, which emerge at *E*, and would be effectual if they came to the eye, are refracted less than the violet ones, and therefore pass below the eye. The intermediate drops between *F* and *E* will for the same reasons be of the intermediate colours.

Thus we have shewn why a set of drops from *F* to *E*, as they are falling, should appear of the primary colours, red, orange, yellow, green, blue, indigo, and violet. It is not necessary that the several drops, which produce these colours, should all of them fall at exactly the same distance from the eye. The angle FOP, for instance, is the same whether the distance of the drop from the eye is OF, or whether it is in any other part of the line OF something nearer to the eye. And whilst the angle FOP is the same, the angle made by the emerging and incident rays, and consequently the colour of the drop, will be the same. This is equally true of any other drop. So that although in the figure the drops *F* and *E* are represented as falling perpendicularly one under the other, yet this is not necessary in order to produce the bow.

But the coloured line FE, which we have already accounted for, is only the breadth of the bow. It still remains to be shewn, why not only the drop *F* should appear red, but why all the other drops quite from *A* to *B* in the arc ATFB should appear of the same colour. Now it is evident, that where-ever a drop of rain is placed, if the angle, which the effectual rays make with the line LP is equal to the angle FOP, that is, if the angle which the effectual rays make with the incident rays is 42 degrees 2 minutes; any of those drops will be red, for the same reason that the drop *F* is of this colour.

If FOP was to turn round upon the line OP, so that one end of this line should always be at the eye, and the other be at *P* opposite to the sun; such a motion of this figure would be like that of a pair of compasses turning round upon one of the legs OP with the opening FOP. In this revolution the drop *F* would describe a circle, *P* would be the centre, and ATFB would be an arc in this circle. Now since, in this motion of the line and drop OF, the angle made by FO with OP, that is, the angle FOP, continues the same; if the sun was to shine upon this drop as it revolves, the effectual rays would make the same angle

angle with the incident rays, in whatever part of the arc ATFYB the drop was to be. Therefore, whether the drop is at A, or at T, or at Y, or at B, or where-ever else it is in this whole arc, it would appear red, as it does at F. The drops of rain, as they fall, are not indeed turned round in this manner; but then, as innumerable of them are falling at once in right lines from the cloud, whilst one drop is at F, there will be others at Y, at T, at B, at A, and in every other part of the arc ATFYB: and all these drops will be red for the same reason that the drop F would have been red, if it had been in the same place. Therefore, when the sun shines upon the rain as it falls, there will be a red arc ATFYB opposite to the sun. In the same manner, because the drop E is violet, we might prove that any other drop, which, whilst it is falling, is in any part of the arc AVEXB, will be violet, and consequently, at the same time that the red arc ATFYB appears, there will likewise be a violet arc AVEXB below or within it. FE is the distance between these two coloured arcs; and from what has been laid it follows, that the intermediate space between these two arcs will be filled up with arcs of the intermediate colours, orange, yellow, blue, green, and indigo. All these coloured arcs together make up the primary rainbow.

The primary rainbow is never a greater arc than a semicircle.

Since the line LOP is drawn from the sun through the eye of the spectator, and since P (No. 46.) is the centre of the rainbow; it follows, that the centre of the rainbow is always opposite to the sun. The angle FOP is an angle of 42 degrees 2 minutes, as was observed, or F the highest part of the bow is 42 degrees 2 minutes from P the centre of it. If the sun is more than 42 degrees 2 minutes high, P the centre of the rainbow, which is opposite to the sun, will be more than 42 degrees 2 minutes below the horizon; and consequently F the top of the bow, which is only 42 degrees 2 minutes from P, will be below the horizon; that is, when the sun is more than 42 degrees 2 minutes high, no primary rainbow will be seen. If the sun is something less than 42 degrees 2 minutes high, then P will be something less than 42 degrees 2 minutes below the horizon; and consequently F, which is only 42 degrees 2 minutes from P, will be just above the horizon; that is, a small part of the bow at this height of the sun will appear close to the ground opposite to the sun. If the sun is 20 degrees high, then P will be 20 degrees below the horizon; and F the top of the bow, being 42 degrees 2 minutes from P, will be 22 degrees 2 minutes above the horizon; therefore, at this height of the sun, the bow will be an arc of a circle whose centre is below the horizon; and consequently that arc of the circle, which is above the horizon, or the bow, will be less than a semicircle. If the sun is in the horizon, then P, the centre of the bow, will be in the opposite part of the horizon; F, the top of the bow, will be 42 degrees 2 minutes above the horizon; and the bow itself, because the horizon passes thro' the centre of it, will be a semicircle. More than a semicircle can never appear; because if the bow was more than semicircle, P the centre of it must be above the horizon; but P is always opposite to the sun, therefore P cannot be above the horizon, unless the sun is below it; and when the sun is set, or is below the horizon, it cannot shine upon the drops of rain, as they fall; and consequently, when the sun is below the horizon, no bow at all can be seen.

When the rays of the sun fall upon a drop of rain, some of them, after two reflections and two refractions, may come to the eye of a spectator, who has his back towards the sun and his face towards the drop.

If *hgw*, (No. 45.) is a drop of rain, and parallel rays coming from the sun, as *zv*, *yw*, fall upon the lower part of it, they will be refracted towards the perpendiculars *vl*, *wl*, as they enter into it, and will describe some such lines as *vb*, *wi*. At *b* and *i* great part of these rays will pass out of the drop; but some of them will be reflected from thence in the lines *hf*, *ig*. At *f* and *g* again, great part of the rays, that were reflected thither, will pass out of the drop. But these rays will not come to the eye of a spectator at *e*. However, here again all the rays will not pass out; but some few will be reflected from *f* and *g*, in some such lines as *fd*, *gd*; and these, when they emerge out of the drop of water into the air at *b* and *d*, will be refracted from the perpendiculars, and, describing the lines *dt*, *bo*, may come to the eye of a spectator who has his back towards the sun and his face towards the drop.

Those rays, which are parallel to one another after they have been once refracted and once reflected in a drop of rain, will be effectual when they emerge after two refractions and two reflections.

No rays can be effectual, unless they are contiguous, and parallel. From what was said, it appears, that when rays come out of a drop of rain contiguous to one another, either after one or after two reflections, they must enter the drop nearly at one and the same place. And if such rays as are contiguous are parallel after the first reflection, they will emerge parallel, and therefore will be effectual. Let *zv* and *yw* be contiguous rays which come from the sun, and are parallel to one another when they fall upon the lower part of the drop *hgw*, (No. 45.) suppose these rays to be refracted at *v* and *w*, and to be reflected at *b* and *i*; if they are parallel to one another, as *hf*, *gi*, after this first reflection, then, after they are reflected a second time from *f* and *g*, and refracted a second time as they emerge at *d* and *b*, they will go out of the drop parallel to one another in the lines *dt* and *bo*, and will therefore be effectual.

The rays *zv*, *yw*, are refracted towards the perpendiculars *vl*, *wl*, when they enter the drop, and will be made to converge. As these rays are very oblique, their focus will not be far from the surface *vw*. If this focus is at *k*, the rays, after they have passed the focus, will diverge from thence in the directions *kb*, *ki*; and if *ki* is the principal focal distance of the concave reflecting surface *hi*, the reflected rays *hf*, *ig*, will be parallel. These rays *hf*, *ig*, are reflected again from the concave surface *fg*, and will meet in a focus at *e*, so that *ge* will be the principal focal distance of this reflecting surface *fg*. And because *hi* and *fg* are parts of the same sphere, the principal focal distances *ge* and *ki* will be equal to one another. When the rays have passed the focus *e*, they will diverge from thence in the lines *ed*, *eb*; and we are to shew, that, when they emerge at *d* and *b*, and are refracted there, they will become parallel.

Now if the rays *vk*, *wk*, when they have met at *k*, were to be turned back again in the directions *kv*, *kw*, and were to emerge at *v* and *w*, they would be refracted into the lines of their incidence *vz*, *wy*, and therefore would be parallel. But since *ge* is equal to *ik*, as has already been shewn, the

rays ed , eb , that diverge from e , fall in the same manner upon the drop at d and b , as the rays kv , kw , would fall upon it at v and w ; and ed , eb , are just as much inclined to the refracting surface db , as kv , kw , would be to the surface vw . From hence it follows, that the rays ed , eb , emerging at d and b , will be refracted in the same manner, and will have the same direction in respect of one another, as kv , kw , would have. But kv and kw would be parallel after refraction. Therefore ed and eb will emerge in lines dp , bp , so as to be parallel to one another, and consequently so as to be effectual.

When rays that are effectual emerge from a drop of rain after two reflections and two refractions, those which are most refrangible will at their emergence make a greater angle with the incident rays than these do which are least refrangible; and by this means the rays of different colours will be separated from one another.

If rays of different colours, which are differently refrangible, emerge at any point b , (No. 45.) these rays will not be all of them equally refracted from the perpendicular. Thus, if bo is a red ray, which is of all others the least refrangible, and bm is a violet ray, which is of all others the most refrangible; when these two rays emerge at b , the violet ray will be refracted more from the perpendicular bx than the red ray, and the refracted angle xbm will be greater than the refracted angle xbo . From hence it follows, that these two rays, after emergence, will diverge from one another. In like manner, the rays that emerge at d will diverge from one another; a red ray will emerge in the line dp , a violet ray in the line dt . So that though all the effectual red rays of the beam $bdmt$ are parallel to one another, and all the effectual red rays of the beam $bdop$ are likewise parallel to one another, yet the violet rays will not be parallel to the red ones, but the violet beam will diverge from the red beam. Thus the rays of different colours will be separated from one another.

This will appear farther, if we consider what the proposition affirms. That any violet or most refrangible ray will make a greater angle with the incident rays, than any red or least refrangible ray makes with the same incident rays. Thus if yw is an incident ray, bm a violet ray emerging from the point b , and bo a red ray emerging from the same point; the angle which the violet ray makes with the incident one is ym , and that which the red ray makes with it is yo . Now ym is a greater angle than yo . For in the triangle bms the internal angle bms is less than bry the external angle at the base. Euc. b. I. prop. 16. But ym is the complement of bms or of bry to two right ones, and yo is the complement of bry to two right ones. Therefore, since bry is less than bys , the complement of bry to two right angles will be greater than the complement of bys to two right angles; or ym will be greater than yo .

Or otherwise: Both the rays bo and bm , when they are refracted in passing out of the drop at b , are turned round upon the point b from the perpendicular bx . Now either of these lines bo or bm might be turned round in this manner, till it made a right angle with yw . Consequently, that ray which is most turned round upon b , or which is most refracted, will make an angle with yw that will be nearer to a right one than that ray makes with it which is least turned round upon b , or which is least refracted. Therefore

that ray which is most refracted will make a greater angle with the incident ray than that which is least refracted.

But since the emerging rays, as they are differently refrangible, make different angles with the same incident ray yw , the refraction which they suffer at emergence will separate them from one another.

The angle ym , which the most refrangible or violet rays make with the incident ones, is found by calculation to be 54 degrees 7 minutes; and the angle yo , which the least refrangible or red rays make with the incident ones, is found to be 50 degrees 57 minutes: the angles, which the rays of the intermediate colours, indigo, blue, green, yellow, and orange, make with the incident rays, are intermediate angles between 54 degrees 7 minutes and 50 degrees 57 minutes.

If a line is supposed to be drawn from the centre of the sun through the eye of the spectator: the angle, which, after two refractions and two reflections, any effectual ray makes with the incident ray, will be equal to the angle which it makes with that line.

If yw , (No. 45.) is an incident ray, bo an effectual ray, and qn a line drawn from the centre of the sun through o the eye of the spectator: the angle yso , which the effectual ray makes with the incident ray, is equal to son the angle which the same effectual ray makes with the line qn . For ywo and qn , considered as drawn from the centre of the sun, are parallel; bo crosses them, and consequently makes the alternate angles yso , son , equal to one another. Euc. b. I. prop. 29.

When the sun shines upon the drops of rain as they are falling: the rays that come from those drops to the eye of a spectator, after two reflections and two refractions, produce the secondary rainbow.

The secondary rainbow is the outermost CHD, No. 46. When the sun shines upon a drop of rain H ; and the rays HO , which emerge at H so as to be effectual, make an angle HOP of 54 degrees 7 minutes with LOP a line drawn from the sun through the eye of the spectator; the same effectual rays will make likewise an angle of 54 degrees 7 minutes with the incident rays S , and the rays which emerge at this angle are violet ones, by what was observed above. Therefore, if the spectator's eye is at O , none but violet rays will enter it: for as all the other rays make a less angle with OP , they will fall above the spectator's eye. In like manner, if the effectual rays that emerge from the drop G make an angle of 50 degrees 57 minutes with the line OP , they will likewise make the same angle with the incident rays S ; and consequently, from the drop G to the spectator's eye at O , no rays will come but red ones; for all the other rays, making a greater angle with the line OP , will fall below the eye at O . For the same reason, the rays emerging from the intermediate drops between H and G , and coming to the spectator's eye at O , will emerge at intermediate angles, and therefore will have the intermediate colours. Thus, if there are seven drops from H to G inclusively, their colours will be violet, indigo, blue, green, yellow, orange and red. This coloured line is the breadth of the secondary rainbow.

Now, if HOP was to turn round upon the line OP , like a pair of compasses upon one of the legs OP with the opening HOP , it is plain from the supposition, that, in such a revolution of the drop H , the angle HOP would be the same,

N. 17.

the, and consequently the emerging rays would make the same angle with the incident ones. But in such a revolution a drop would describe a circle of which P would be the centre and CNHRD an arc. Consequently, since, when a drop is at N, or at R, or any where else in that arc, the emerging rays make the same angle with the incident rays as when the drop is at H, the colour of the drop will be the same to an eye placed at O, whether the drop is at N, or at H, or at R, or any where else in that arc. Now, though the drop does not thus turn round as it falls, it does not pass through the several parts of this arc, yet, since there are drops of rain falling every where at the same time, when one drop is at H, there will be another at R, another at N, and others in all parts of the arc; and these drops will all of them be violet-coloured, for the same reason that the drop H would have been of this colour if it had been in any of those places. In like manner, as the drop G is red when it is at G, it would likewise be red in any part of the arc CWGQD; and so will any other drop, when, as it is falling, it comes to any part of that arc. Thus as the sun shines upon the rain, whilst it falls, there will be two arcs produced, a violet coloured one CNHRD, and a red one CWGQD; and for the same reasons the intermediate space between these two arcs will be filled up with arcs of the intermediate colours. All these arcs together make up the secondary rainbow.

The colours of the secondary rainbow are fainter than those of the primary rainbow; and are ranged in the contrary order.

The primary rainbow is produced by such rays as have been only once reflected; the secondary rainbow is produced by such rays as have been twice reflected. But at every reflection some rays pass out of the drop of rain without being reflected; so that the oftener the rays are reflected, the fewer of them are left. Therefore the colours of the secondary bow are produced by fewer rays, and consequen-

ly will be fainter, than the colours of the primary bow.

In the primary bow, reckoning from the outside of it, the colours are ranged in this order; red, orange, yellow, green, blue, indigo, violet. In the secondary bow, reckoning from the outside, the colours are violet, indigo, blue, green, yellow, orange, red. So that the red, which is the outermost or highest colour in the primary bow, is the innermost or lowest colour in the secondary one.

Now the violet rays, when they emerge so as to be effectual after one reflection, make a less angle with the incident rays than the red ones; consequently the violet rays make a less angle with the lines OP, (No. 46.) than the red ones. But in the primary rainbow the rays are only once reflected, and the angle which the effectual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops or violet arc in the primary bow will be nearer to the centre of the bow, than the red drops or red arc; that is, the innermost colour in the primary bow will be violet, and the outermost colour will be red. And, for the same reason, through the whole primary bow, every colour will be nearer to the centre P, as the rays of that colour are more refrangible.

But the violet rays, when they emerge so as to be effectual after two reflections, make a greater angle with the incident rays than the red ones; consequently the violet rays will make a greater angle with the line OP, than the red ones. But in the secondary rainbow the rays are twice reflected, and the angle which effectual rays make with OP is the distance of the coloured drop from P the centre of the bow. Therefore the violet drops or violet arc in the secondary bow will be farther from the centre of the bow than the red drops or red arc; that is, the outermost colour in the secondary bow will be violet, and the innermost colour will be red. And, for the same reason, thro' the whole secondary bow, every colour will be further from the centre P, as the rays of that colour are more refrangible.

O R A

OPTIMATES, in Roman antiquity, were, according to Tully, the best citizens, who desired their actions might be approved of by the better sort; and the populares, those who, out of a thirst of vain-glory, did not consider so much what was right, as what would please the populace.

OPUNTIA, in botany. See CACTUS.

OR, in heraldry, denotes yellow, or gold colour. See COLOUR and METAL.

In the coats of noblemen, it is blazoned topaz; and in those of sovereign princes, sol.

It is represented in engraving by small points or dots, scattered all over the field or bearing. See Pl. 134. fig. 5.

ORACLE, among the heathens, was the answer which the gods were supposed to give to those who consulted them upon any affair of importance; it is also used for the god who it was thought gave the answer, and the place where it was given.

The credit of oracles was so great, that in all doubts and disputes their determinations were held sacred and inviolable: whence vast numbers flocked to them for advice about the management of their affairs; and no business of any consequence was undertaken, scarce any

O R A

peace concluded, any war waged, or any new form of government instituted, without the advice and approbation of some oracle. The answers were usually given by the intervention of the priest or priestess of the god who was consulted; and generally expressed in such dark and intermediate phrases, as might be easily wrested to prove the truth of the oracle whatever was the event. It is not, therefore, to be wondered at, that the priests who delivered them were in the highest credit and esteem; and that they improved this reputation greatly to their advantage. They accordingly allowed no man to consult the gods, before he had offered costly sacrifices, and made rich presents to them. And to keep up the veneration for their oracles, and to prevent their being taken unprepared, they admitted persons to consult the gods only at certain stated times; and sometimes they were so cautious, that the greatest persons could obtain no answer at all. Thus Alexander himself was preemptorily denied by the pythia, or priestess of Apollo, till she was, by downright force, obliged to ascend the tripod; when, being unable to resist any longer, she cried out, *thou art invincible*; and these words were accepted instead of a farther oracle. See MYTHOLOGY.

ORACH.

ORACHI, in botany. See *ATRIPLEX*.

ORAL, something delivered by word of mouth, without being committed to writing; in which sense we say, oral law, oral tradition, &c.

ORANGE-TREE, in botany. See *CITRUS*.

ORANGE, in geography, a city of Provence, in France, capital of the principality of Orange; it is situated on the east side of the river Rhone, seventeen miles north of Avignon: E. long. $4^{\circ} 46'$, N. lat. $44^{\circ} 10'$.

ORATION, in rhetoric, a speech or harangue, composed according to the rules of oratory, and spoken in public.

Orations may be all reduced to three kinds, *viz.* the demonstrative, deliberative, and judicial. To the demonstrative kind belong panegyrics, genethliaca, epithalamia, congratulations, &c. To the deliberative kind belong persuasion, exhortation, &c. And to the judicial kind belong accusation, confutation, &c.

ORATORIO, in the Italian music, a sort of sacred drama of dialogues; containing recitatives, duettos, trios, ritornellos, choruses, &c.

The subjects of these pieces are usually taken from the scriptures, or from the life of some saint, &c.

The music for the oratorio should be in the finest taste, and best chosen strains. These oratorios are greatly used at Rome, in time of lent; and of late, in England.

ORATORY, See *RHETORIC*.

ORATORY, among the Romanists, a closet or like apartment near a bed-chamber, furnished with an altar, crucifix, &c. for private devotion.

ORB, in astronomy, &c. denotes an hollow globe or sphere.

ORBICULARIS, in anatomy. See *ANATOMY*, p. 306.

ORBIS, in ichthyology, a name given to two species of ostracion, nearly as broad as long, and covered with spines. See *OSTRACION*.

ORBIS MAGNUS, in astronomy, denotes the earth's orbit, in its annual revolution round the sun.

ORBIT, in astronomy, the path of a planet or comet, or the curve that it describes in its revolution round its central body: thus the earth's orbit is the curve which it describes in its annual course, and usually called the elliptic. See *ASTRONOMY*.

ORCADES, the ORKNEY-ISLANDS. See *ORKNEY*.

ORCHARD, a plantation of fruit-trees. See *GARDENING*.

ORCHESTRA, in the ancient theatres, a place in the form of a semi-circle, where the dancing was performed.

In the Greek theatres, the orchestra made part of the stage; but, among the Romans, it answered nearly to our pit; only that in it were disposed the seats for the senators, magistrates, vestals, and other persons of distinction.

ORCHIS, in botany, a genus of the gynandria diandria class. The nectarium is shaped like a horn behind the flower. There are 32 species, 12 of them natives of Britain. The root of the morio, or female fool-stones, has been celebrated as an aphrodisiac, but without any solid foundation.

ORDEAL, a form of trial, or of discovering innocence or guilt, formerly practised over almost all Europe, and which prevailed in England from the time of Edward the Confessor, till it was abolished by a declaration of Henry III. It was called *purgatio vulgaris*, or *judicium*; in

opposition to bellum or combat, the other form of punishment; and was of various kinds, as that of fire, that of red-hot-iron, that of water, that of judicial potage, that of hallowed cheese, that of the green cross, and that of dice laid on relics covered with a woollen cloth. To each of which kinds particular masses were appointed.

In England, an offender, on being arraigned and pleading not guilty, had it in his choice to put himself upon God and his country; that is, upon the verdict of a jury; or upon God alone, on which account it was called the judgment of God, it being presumed that God would deliver the innocent. The more popular kinds of ordeals were those of red-hot iron and water; the first for free men and people of fashion, and the last for peasants. That by fire, as practised here, was the person's walking bare-footed and blindfold over nine red-hot ploughshares, and if he escaped unhurt, he was acquitted; otherwise condemned. That of water was of two kinds, *viz.* either with hot water, or cold: the former was where the person suspected put his arm or leg into scalding water and brought it out unhurt; and the latter was when his body was not, contrary to the course of nature, borne up by the water.

ORDER, in architecture, is a system of the several members, ornaments, and proportions of columns and pilasters; or a regular arrangement of the projecting parts of a building, especially the column, so as to form one beautiful whole. See *ARCHITECTURE*.

ORDER is also used for a division or class of any thing: thus, the tribe of animals called birds is subdivided into six orders. See *NATURAL HISTORY*, and *BOTANY*.

Holy ORDERS, a character peculiar to ecclesiastics, whereby they are set apart for the ministry. See *ORDINATION*.

Military ORDERS, are companies of knights, instituted by kings and princes; either for defence of the faith, or to confer marks of honour, and make distinctions among their subjects.

Religious ORDERS, are congregations or societies of monastics, living under the same superior, in the same manner, and wearing the same habit.

ORDINAL, a book containing the order or manner of performing divine service.

ORDINANCE, or ORDONNANCE, a law, statute, or command of a sovereign or superior: thus the acts of parliament are sometimes termed ordinances of parliament.

ORDINARY, in civil law, is any judge invested with authority to take cognizance of causes in his own right, and not by deputation.

ORDINARY, or honourable ORDINARY, in heraldry, a denomination given to certain charges properly belonging to that art. The honourable ordinaries are ten in number; *viz.* the chief, pale, bend, fesse, bar, cross, saltier, chevron, bordure, and orle. For which see the articles *CHIEF*, *PALE*, &c.

ORDINATES. See *CONIC SECTIONS*.

ORDINATION, the act of conferring holy orders, or of initiating a person into the priesthood by prayer and the laying on of hands.

ORDNANCE, a general name for all sorts of great guns used in war. See *GUNNERY*.

Office of ORDNANCE, an office kept within the tower of London, which superintends and disposes of all the arms, instruments, and utensils of war, both by sea and land.

in all the magazines, garisons, and forts, in Great Britain.
ORDONNANCE, in architecture, is the composition of a building, and the disposition of its parts, both with regard to the whole and to one another; or, as Mr. Evelyn expresses it, determining the measure of what is assigned to the several apartments.

ORE, in natural history, the compound mineral glebe, earth, stone, or other substance, which is rich enough in metallic particles to be worth the while of being purified, and by this means to separate the metal from it, whether gold, silver, copper, &c. See **CHEMISTRY**.

OREBRO, the capital of the province of Nericia, in Sweden: E. long. 15°, N. lat. 59° 20'.

OREGRUND, a port-town of Sweden, in the province of Upland: E. long. 18° 15', N. lat. 60° 30'.

ORFORD, a borough and port town of Suffolk, thirty miles east of Bury. It sends two members to parliament.

ORGAL, among dyers, denotes the lees of wine dried.

ORGAN, in general, is an instrument or machine designed for the production of some certain action or operation; in which sense, the mechanic powers, machines, and even the veins, arteries, nerves, muscles, and bones of the human body, may be called organs.

ORGAN, in music, the largest and most harmonious wind-instrument.

The invention of the organ is very ancient, though it is agreed that it was very little used till the eighth century. It seems to have been borrowed from the Greeks. Vitruvius describes an hydraulic one in his tenth book of architecture. The emperor Julian has an epigram in its praise. St. Jerome mentions one with twelve pair of bellows, which might be heard a thousand paces, or a mile; and another at Jerusalem, which might be heard at the mount of Olives.

There is one in the cathedral church of Ulm, in Germany, that is ninety-three feet high, and twenty-eight broad; the biggest pipe is thirteen inches in diameter; and it has sixteen pair of bellows.

The modern organ is a buffet, containing several rows of pipes. The size of the organ is generally expressed by the length of its biggest pipe; thus we say an organ of thirty-two feet, of sixteen, of eight, and of two feet.

Hydraulic ORGAN, denotes a musical machine that plays by means of water instead of wind. Of these there are several in Italy in the grottoes of vineyards. Ctesibes of Alexandria, who lived in the time of Ptolemy Euergetes, is said to have first invented organs that played by compressing the air with water, as is still practised. Archimedes and Vitruvius have left us descriptions of the hydraulic organ.

ORGASM, an ecstasy, or impetuous desire of coition, occasioned by a turgescency of the feminal vessels.

ORGIA, in antiquity, feasts and sacrifices performed in honour of Bacchus, instituted by Orpheus, and chiefly celebrated on the mountains by wild distracted women, called Bacchæ. See **BACCHANALIA**, and **DIONYSIA**.

ORGIVA, a town of Spain, in the province of Granada, twenty-five miles south of Granada.

ORGUES, in the military art, are thick, long pieces of wood, pointed at one end, and shod with iron, clear one of another; hanging each by a particular rope, or cord, over the gate-way of a strong place, perpendicularly, to be let fall in case of an enemy.

ORGUES is also used for a machine, composed of several harquebuses or musquet-barrels bound together, by means whereof several explosions are made at the same time, used to defend breaches and other places attacked.

ORGYA, an ancient Grecian measure, containing six feet.

ORIA, a town of Italy, in the kingdom of Naples, and territory of Otranto, situated thirty miles north-west of the city of Otranto.

ORIFICE, the mouth or aperture of a tube, pipe, or other cavity.

ORIGANUM, in botany, a genus of the didymia gymnosperma class. The strobilus is triangular and spiked. There are eleven species, two of which are natives of Britain, viz. the vulgare, or wild marjoram; and the onites, or pot-marjoram.

ORIGENISTS, in church-history, a Christian sect in the fourth century, so called from their drawing their opinions from the writings of Origen. The origenists maintained, that the souls of men had a pre-existent state; that they were holy intelligences, and had sinned in heaven before the body was created: that Christ is only the son of God by adoption: that he has been successively united with all the angelical natures, and has been a cherub, a seraph, and all the celestial virtues, one after another: that in future ages, he will be crucified for the salvation of the devils, as he has already been for that of men; and that their punishment, and that of the damned, will continue only for a certain limited time.

ORIGINAL, a first draught or design of any thing, which serves as a model to be imitated or copied.

ORIGINAL SIN, the crime of eating the forbidden fruit, of which it is said all mankind are guilty at their conception by the imputation of Adam's transgression; which is accounted for by supposing, that Adam, as he was to be the father, was also the federal head and representative, of the whole human race; and that on his sinning, all that were to spring from him partook of his crime.

ORIGUELLA, a city of Spain, in the province of Valencia: W. long. 50°, N. lat. 38° 20'.

ORILLON, in fortification, is a small rounding of earth faced with a wall; raised on the shoulder of those bastions that have casemates, to cover the cannon in the retired flank, and prevent their being dismounted by the enemy. See **FORTIFICATION**.

ORIOLOUS, in ornithology, a genus belonging to the order of pica. The bill is conical, convex, very sharp, and straight, the superior mandible being much longer than the under one; and the tongue is forked and sharp. There are 20 species, principally distinguished by their colour.

ORION, in astronomy. See **ASTRONOMY**, p. 487.

ORIXA, the capital of the province of the same name, in the hither India, situated on the west side of the bay of Bengal.

ORKNEY ISLANDS, certain islands on the north of Scotland, from which they are separated by a frith twenty miles in length, and ten in breadth. These islands are forty in number, and together with the island of Zetland send one member to parliament, and another for the burghs of Kirkwall, &c.

ORLE, **ORLET**, or **ORLO**, in architecture, a fillet under the ovolo or quarter round of a capital. When it is at the top or bottom of the shaft, it is called cincture.

Palladio uses the word orlo, for the plinth of the bases of the columns.

ORLE, in heraldry, an ordinary, in form of a fillet, drawn round the shield, near the edge or extremity thereof, leaving the field vacant in the middle. Its breadth is but half that of the tressure or bordure, which contains a sixth part of the shield; and the orle, only a twelfth: besides that the orle is its own breadth distant from the edge of the shield, whereas the bordure comes to the edge itself. The form of the orle is the same with that of the shield, whence it resembles an escutcheon. See Plate CXXXIV. fig. 6. which represents an orle argent in a field gules.

ORLEANOIS, a province or government of France, bounded by Normandy and the isle of France, on the north; by Champaign and Burgundy, on the east; by Lyonn's and Guienne, on the south; and by Britany and the bay of Biscay, on the west.

ORLEANS, a city of France, capital of Orleanois, situated on the river Loire, in E. long. 2° , N. lat. $47^{\circ} 55'$.

ORLEANS is also the name of an island and town on the river of St. Laurence, in Canada: W. long. 73° , N. lat. 47° .

ORLOPE, in the sea-language, the uppermost space or deck in a great ship, reaching from the main-mast to the mizen. In three-deck ships, the second and lowest decks are sometimes called orlopes.

ORMOND, the north division of the county of Tipperary in Ireland.

ORMUS, an island at the entrance of the gulph of Persia, situated opposite to Gombron on the continent, in E. long. 56° , N. lat. $27^{\circ} 30'$.

This island is thirty miles in circumference.

ORNITHOGALUM, in botany, a genus of the hexandria monogynia class. The corolla consists of six erect petals; and the filaments are alternately wider at the base. There are 11 species, three of them natives of Britain, viz. the luteum, or yellow star of Bethlehem; the pyrenaicum, or spiked star of Bethlehem; and the umbellatum, or common star of Bethlehem.

ORNITHOLOGY, that branch of natural history which treats of birds. See NATURAL HISTORY.

ORNITHOMANCY, a species of divination, performed by means of birds; being the same with augury. See DIVINATION and AUGURY.

ORNIOPHTUS, in botany, a genus of the diadelphia decandria class. The pod is jointed, cylindrical, and arcuated. There are four species, only one of which, viz. the perpusillus, or birds-foot, is a native of Britain.

OROBANCHE, in botany, a genus of the didynamia angiospermia class. The calix is biseid, and the corolla ringent; the capsule has two valves, and contains many seeds. There are seven species, two of them natives of Britain, viz. the major, or broom-rape; and the ramosa, or branched broom-rape.

OROBUS, in botany, a genus of the diadelphia decandria class. The stylus is linear; the calix is blunt at the base, the superior segments of it being shorter. There are nine species, two of them natives of Britain, viz. the tuberosus, or wood-pease; and the sylvaticus, or bitter vetch.

ORONOQUE, a river of South America, which falls into

the Atlantic ocean in 8° N. lat. almost opposite to the island of Trinity.

ORONTIUM, in botany, a genus of the hexandria monogynia class. The spadix is cylindrical, and covered with floeules; the corolla consists of six petals; it has no sty- lus; and the capsule has three cells. There is but one species, a native of Virginia.

ORPHAN, a fatherless child, or minor; or one that is deprived both of father and mother.

ORPHUS, in ichthyology. See SPARUS.

ORPIMENT, in natural history, a yellow substance usually found in copper-mines, composed of thin flakes, like the tales; which easily split, and are flexible, and not elastic, soluble in oil, fusible in a moderate fire, and yielding in burning an offensive smell like garlic.

Of this genus of fossils, there are only three known species: 1. A broad-flaked, gold-coloured kind, much esteemed at present by our painters. This is found in several places, as in the islands of the Archipelago, in the mines of Gosselaer in Saxony, in some parts of Turkey, and in the East-Indies, and in its utmost purity about Smyrna; this makes the finest of all yellows in painting. 2. The small-flaked yellow kind, which is the common orpiment of the shops, and is a fine colour, though greatly inferior to the former. This is found in many parts of the Turkish dominions, and in Germany. And, 3. Red-orpiment, which is of a fine bright red; this is a very beautiful substance of a fine bright red, very glossy, and a little transparent, and is found in the Turkish dominions, in the islands of the Archipelago, and even in Cornwall, where it is known under the name of red mundic.

Goeffroy declares it a corrosive and poisonous mineral: on the other hand, Boerhaave declares orpiment an innocent and harmless medicine; and Hoffman, who has been at more pains than any body to examine into its nature, declares the same, and even gives instances of its being given to dogs without any harm.

It is an excellent depilatory, mixed with lime, and made into a paste with water. The painters are fond of it as a golden colour; and a lixivium of it, with quick-lime, makes sympathetic ink.

ORPINE, in botany. See SEDUM.

ORRERY, a curious machine, or movement, for representing the motions and appearances of the heavenly bodies. See ASTRONOMY, P. 495.

ORRICE. See IRIS.

ORTEGAL castle and cape, the most northerly promontory of Spain, thirty miles north-east of Ferrol: W. long. $8^{\circ} 22'$, N. lat. 44° .

ORTEGIA, in botany, a genus of the triandria monogynia class. The calix consists of five leaves; the corolla is wanting; and the capsule has one cell, and many seeds. There is but one species, a native of Spain.

ORTHODOX, in church-history, an appellation given to those who are found in all the articles of the Christian faith.

ORTHOGRAPHIC projection of the sphere, that where-in the eye is supposed at an infinite distance; so called, because the perpendiculars from any point of the sphere will all fall in the common intersection of the sphere, with the plane of the projection.

ORTHO-

ORTHOGRAPHY, that part of grammar which teaches the nature and affections of letters, and the just method of spelling or writing words with all the proper and necessary letters, making one of the four greatest divisions or branches of grammar. See **GRAMMAR**.

ORTHOGRAPHY, in geometry, the art of drawing or delineating the fore-right plan of any object, and of expressing the heights or elevations of each part. It is called orthography, from its determining things by perpendicular lines falling on the geometrical plane.

ORTHOGRAPHY, in architecture, the elevation of a building.

ORTHOGRAPHY, in perspective, is the fore-right side of any plane, *i. e.* the side or plane that lies parallel to a straight line, that may be imagined to pass through the outward convex points of the eyes, continued to a convenient length.

ORTHOPNOEA, in-medicine, a species or degree of asthma, where there is such a difficulty of respiration, that the patient is obliged to sit or stand upright, to be able to breathe. See **MEDICINE**.

ORTON, a market town of Westmoreland, situated ten miles south-west of Appleby.

ORVALA, in botany, a genus of the didynamia gymnospermia class. The superior lip of the corolla is divided into three segments, each being toothed; and the inferior lip is cordated and crenated. There is but one species, a native of Italy.

ORVIETTO, a city of Italy; in the pope's territories, capital of the province of Orvietto, situated at the confluence of the Tiber and the Chiane: E. long. 13°, N. lat. 43°.

ORWELL, a river of Suffolk, which, rising in the middle of that country, runs south-east by Ipswich, and falls into the German sea at Langard-fort.

ORYZA, rice, in botany, a genus of the hexandria digynia class. The calix is a double-valved glume, with one flower; and the corolla consists of two equal valves. There is but one species.

This plant is cultivated in vast abundance in the East, as also in Carolina, for food. It is said to be good in dysenteries, diarrhoeas, &c.

OSACA, a great city and port-town of Japan, situated on a bay of the sea, on the east side of the island: in E. long. 135°, N. lat. 35°.

OSBECKIA, in botany, a genus of the octandria monogynia class. The calix consists of four segments, and the corolla of four petals; and the capsule has four cells. There is but one species, a native of India.

OSCHEOCELE, in surgery, a hernia of the scrotum. See **SURGERY**.

OSCILLATION, in mechanics, the vibration, or reciprocal ascent and descent of a pendulum. See **MECHANICS**.

OSMUNDA, in botany, a genus of the cryptogamia filicum class. The spike is full of branches, and the fructification is round. There are 17 species, none of them natives of Britain.

OSNABURG, the capital of the bishopric of the same name, in the circle of Westphalia: E. long. 7° 40', N. lat. 52° 21'. The territories of this bishopric, which are forty miles long, and thirty broad, are subject to its bishop: and this bishopric is alternately held by a protestant and

papist, the protestant being always a prince of the house of Brunswick.

OSORNO, a town of Chili in South America: W. long. 80°, S. lat. 41°.

OSPREY. See **FALCO**.

OSSIFICATION, the formation of bones, but more particularly the conversion of parts naturally soft to the hardness and consistence of bones. See **ANATOMY**, p. 148.

OSSORY, the west division of Queen's county in Ireland.

OSSUNA, a town of Spain, in the province of Andalusia, forty miles east of Seville.

OSTAGIO, a town of Italy in the territory of Genoa, fifteen miles north-west of Genoa.

OSTEND, a city and port-town of the Austrian Netherlands, in the province of Flanders, situated twelve miles west of Bruges: E. long. 2° 45', N. lat. 51° 15°.

OSTEOCOLLA, in natural history, though supposed by many to be an earth, is truly a cruftated kind of spar, debased by earth, and therefore not transparent.

It is usually found coating over vegetable, or other bodies, in form of incrustations; so that the true osteocollas is a tubular cruftaceous spar, of a very foul and coarse texture, and carries with it much more of the appearance of a marl than of a species of spar.

The masses of osteocollo, though regularly of the same figure, are very different in size; some of them being not thicker than a crow-quill, and others of five and six inches diameter; it is always, however, of a tubular figure, and a wrinkled and rough surface.

Osteocollo is frequent in Germany, where it is found buried near the surface of the earth, sometimes in strata of sand, but more frequently among marls: it should be chosen for use, the purest that can be had of a pale brown colour, and of a tolerably close and firm texture.

It has long been famous for bringing on a callus in fractured bones; its name osteocollo signifying the bone-glue, or bone-binder. It is also recommended as a diuretic, and as good in the fluxus albus: but, at present, little regard is paid to it; since, if it has any virtues, they must be wholly owing to spar, which may be given to greater advantage in a purer form.

OSTEOLOGY, that branch of anatomy which treats of the bones. See **ANATOMY**, Part I.

OSTEOSPERMUM, in botany, a genus of the syngenesia polygamia necessaria class. The receptacle is naked; it has no pappus; the calix consists of many leaves; and the seeds are round and hard. There are five species, none of them natives of Britain.

OSTIA, a port-town of Italy, in the pope's territories, situated at the mouth of the Tiber: E. long. 13°, N. lat. 41° 30'.

OSTRACION, in zoology, a genus of the amphibia nantes class. It has ten long, cylindrical, obtuse teeth in each jaw; the aperture is linear; the body is covered with a bony substance; and it has no belly-fins. There are nine species, principally distinguished by the angles of their bodies and the number of spines near the tail.

OSTRACISM, in Grecian antiquity, denotes the banishment of such persons whose merit and influence gave umbrage to the people of Athens, lest they should attempt any thing against the public liberty. It was so called, because the people

the voted a person's banishment, by writing his name on shells, and calling them into an urn.

OSTRACITES, in natural history, the name by which authors call the fossil oyster-shell.

Ostracites has the same medicinal virtues with the helminthes, and lapis judaicus, only in a higher degree; being accounted by Dr. Lister one of the greatest known medicines in nephritic cases: the dose, in powder, is from half a dram to a dram, in white-wine; and to prevent a sickness at the stomach, that sometimes attends the taking it, one third part of the quantity of powdered chamomile-flowers may be mixed with it.

OSTREA, the **OYSTER**, in zoology, a genus belonging to the order of vermes testacea. The shell has two unequal valves; the cardo has no teeth, but a small hollow pit, with transverse lateral streaks. There are 31 species, principally distinguished by peculiarities in their shells. The common oyster is used both raw, and variously prepared as food.

OSTRICH, in ornithology. See **STRUTHIO**.

OSWEGO, a town of the Iroquois, in North America, three hundred miles west of Albany, in New-York.

OSWESTRY, a market-town in Shropshire, fifteen miles north-west of Shrewsbury.

OSYRIS, in botany, a genus of the diœcia triandria class. The calix of both male and female consists of three segments; neither of them have any corolla; the female has no style, but a roundish stigma; and the drupa has but one cell. There is only one species, a native of Italy.

OTHONNA, in botany, a genus of the syngenesia polygamia necessaria class. The receptacle is naked; it has no pappus; and the calix is somewhat cylindrical, and consists of many leaves. There are seven species, two of them natives of Britain, viz. the palustris, or marsh fleabane; and the integrifolia, or mountain ragwort.

OTIS, in ornithology, a genus of birds belonging to the order of grææ. The superior mandible of the bill is arched; the nostrils are oval; the tongue is bifid; the feet are made for running, being furnished with four toes. There are four species, principally distinguished by their colour:

OTLEY, a market-town, twenty-one miles west of York.

OTOQUE, an island situated in the bay of Panama, from whence the city is furnished with provisions: W. long. 82°, N. lat. 7°.

OTRANTO, a city and archbishop's see of the kingdom of Naples, situated at the entrance of the gulph of Venice: E. long. 19° 15', N. lat. 40° 12'.

OTTER, in zoology. See **MUSTELA**.

OTTOMAN, or **OTHMAN**, an appellation given to the Turkish empire, from Othomannus, or Osmanhus, the first emperor of the present family.

OTTONA, or **ORTONA**, a city of the kingdom of Naples, situated on the gulph of Venice: in E. long. 15° 30', N. lat. 42° 22'.

OVAL, an oblong curvilinear figure, otherwise called ellipsis. See **CONIC SECTIONS**.

OVARIES, in anatomy. See **ANATOMY**, p. 275.

OVATION, in the Roman antiquity, a lesser triumph, allowed to commanders for victories won without the effusion of much blood; or for defeating a mean and considerable enemy. The show generally began at the Albanian mountain, whence the general with his retinue made his entry into the city on foot, with many flutes

and pipes sounding in concert as he passed along, and wearing a garland of myrtle as a token of peace. The term ovation, according to Servius, is derived from *ovis*, sheep, because on this occasion the conqueror sacrificed a sheep, as in triumph it sacrificed a bull.

UDENARDE, a town of the Austrian Netherlands, in the province of Flanders, situated on the river Scheld, thirteen miles south of Ghent.

UDENBURG, a town of the Austrian Netherlands, in the province of Flanders, five miles south-east of Ostend.

OVERHALE, in the sea-language. A rope is said to be overhauled when drawn too stiff, or haled the contrary way.

OVER-RAKE, among seamen: When a ship, riding at anchor, so overbeats herself into an high sea, that she is washed by the waves breaking in upon her, they say the waves over-rake her.

OVERSMAN, in Scots law; a person named by arbiters, or by the parties submitters, to determine the matter submitted, in case the parties disagree in their opinion.

OVERT, the same with open: thus an overt act signifies an act which, in law, must be clearly proved; and such is to be alleged in every indictment for high treason.

OVERTURE, or **OUVERTURE**, opening or prelude; a term used for the solemnities at the beginning of a public act or ceremony; an opera, tragedy, concert of music, &c.

The overture of the theatre, or scene, is a piece of music usually ending with a fugue: the overture of a jubilee is a general procession, &c.

OVERYSCHÉ, a town of the Austrian Netherlands, in the province of Brabant, situated on the river Ysche, nine miles north-east of Brussels.

OVERYSSEL, one of the united provinces, bounded by Groningen on the north, by Westphalia on the east, by Zutphen on the south, and by Guelderland, the Zuydersee, and Friesland, on the west.

OVIEDA, in botany, a genus of the didynamia angiospermia class. The calix consists of five segments; the corolla is a long cylindrical tube; and the berry is round, containing two seeds. There are two species, none of them natives of Britain.

OVIEDO, a city of Spain, capital of the province of Asturias; situated on the river Asa, fifty miles north of Leon, in W. long. 6° 40', N. lat. 43° 30'.

OVILIA, or **SEPTA**, in ancient Rome, a place in the campus martius, at first railed in like a sheep-pen, whence its name. Afterwards it was mounted with marble, and beautified with walks and galleries, as also with a tribunal, or seat of justice. Within this precinct, or inclosure, the people were called in to give their suffrages for the election of magistrates. The ascent into the ovilia was not by stairs, but by pontes, or narrow boards, laid there for the occasion; on which account *de ponte dejecti* was to be denied the privilege of voting; and persons thus dealt with, were called *deponenti*.

OVIPAROUS, a term applied to such animals as bring forth their young from eggs; as birds, insects, &c.

OVIS, in zoology, a genus of the mammalia class, and of the order of pecora; the characters of which are these: The horns are concave, turned backwards, twisted, and full of wrinkles: there are eight foreteeth in the under jaw, and no dog-teeth. The species are three, viz.

1. Arics,

1. *Aries*, or ram and sheep, the horns of which are shaped like a half-moon, and compressed. This animal is perhaps the most gentle and inoffensive, and at the same time the most timid and stupid, of all quadrupeds. In a flock of sheep, there is always a leader, whose steps the rest implicitly and blindly follow. If he runs over a precipice, the whole flock follow his example, and cannot be restrained though evident destruction be the consequence. The smallest noise, if uncommon, makes them run precipitantly against each other, without knowing the cause of their danger, or being able to extricate themselves. In snow, they remain fixed in the same spot; and continue obstinately in that situation, unless they are forced to move by the shepherd or his dog. But though dastardly in itself, though almost devoid of sentiment and mental qualities, this animal is of the most extensive utility to man. It affords us both food and clothing, besides the advantages we derive from its milk, its skin, and its tallow.

Love, the liveliest sentiment in all animals, is the only passion which inspires the ram with any degree of vivacity; when under the influence of this passion, he becomes petulant, runs against his neighbours, and sometimes even attacks the shepherd himself. But the ewe, or female, though in the same situation, does not appear to be in the least affected; she seems to have no other instinct than that of simply admitting the embraces of the ram, eating her food, and recognising her offspring; the lamb, on the other hand, is endowed with the same instinct of distinguishing its mother from the rest of the flock.

This animal, so soft and so simple in its nature and disposition, is likewise extremely weak and feeble in its constitution: They can endure but little fatigue; whenever they run, their hearts palpitate, and their wind fails them; they are equally incapable of bearing heat or cold, snow or rain: They are subject to many diseases, most of which are contagious: They bring forth their young with pain and difficulty, and require more care and attention than any other domestic animal.

The ram is capable of generation at the age of 18 months; and the ewe can be impregnated when a year old. One ram is sufficient for 30 or 40 ewes. He ought to be strong, well proportioned; his head should be thick and strong, his front large, his eyes black, his nose flat, his neck thick, his body long and tall, his testicles massy, and his tail long. White is the best colour for a ram. The ewes whose wool is most plentiful, bushy, long, soft, and white, are most proper for breeders, especially when at the same time they are of a large size, have a thick neck, and move nimbly.

Ewes are generally in season from the end of October to the beginning of April: However, they may be impregnated at any time, if they be fed with stimulating nourishment, as salt water, and bread made of hemp-seed. They go with young about five months; and generally bring forth but one at a time, though frequently two: In warm climates, they may bring forth twice in a year; but in Britain, France, and most parts of Europe, only once. They give milk plentifully for seven or eight months: Their milk affords nourishment for children and country people; good cheese is made of it, especially when mixed with cow-milk. They live from 10 to 12 years, and are capable of bringing forth as long as they live.

When the male lambs are not intended to be kept for propagation, but fattened for food, they ought to be castrated at the age of five or six months. This operation is performed two ways: in the one, an incision is made and the testicles taken out; in the other, a ligature is tied tight round the scrotum, above the testicles, which soon destroys the vessels which nourish them. After castration, they are called wethers.

The ram, ewe, and wether, when one year old, lose the two foreteeth of the under jaw; six months afterwards, they lose the two foreteeth next to these; and at the age of three years, the teeth are all replaced. The age of a ram may likewise be discovered by their horns, which always appear the first year, and frequently as soon as they are brought forth. These horns uniformly acquire an additional ring every year as long as the creature lives. The ewes commonly have no horns, but a kind of long protuberances in place of them: However, some of them have two, and some four horns.

In Spain, and the southern parts of Europe, the flocks are kept in shades or stables during the night: but in Britain, where there is now no danger from wolves, they are allowed to remain without, both night and day; which makes the animals more healthy, and their flesh a more whole food. Dry and mountainous grounds, where thyme and sheep's fescue grafs abound, are the best for the pasturing sheep.

2. The *Guineensis*, or Guinea sheep, has pendulous ears, lax hairy dew lips, and a prominence on the hind part of the head. The wool is short, like that of a goat. It is a native of Guinea.

3. The *strepicerus*, or Cretan sheep, has strait carinated horns, twisted in a spiral manner. It is a native of Mount Iola.

OULNEY, a market-town of Buckinghamshire, situated nine miles south-east of Northampton.

OULZ, a town of Italy, in the province of Piedmont, situated in E. long. 6° 30', N. lat. 45°.

OUNCE, a little weight, the sixteenth part of a pound avoirdupois, and the twelfth part of a pound troy.

OUNCE, in zoology. See **LEO**.

OUNDLE, a market-town of Northamptonshire, situated on the river Nen, twenty-two miles north-east of Northampton.

OVOLO, or **OVUM**, in architecture, a round moulding, whose profile, or sweep, in the ionic and composite capitals, is usually a quadrant of a circle: whence it is also commonly called the quarter-round.

It is usually cut with the representation of eggs and anchors or arrows heads placed alternately.

OUSE, a river, which, rising in the north of Yorkshire, runs south-east by York; and, continuing that course, falls into the Trent.

OUSE, is also a river which rises on the confines of Oxfordshire and Buckinghamshire; and running north east through Buckinghamshire, Bedfordshire, Huntingdonshire, Cambridgeshire, and Norfolk, passes by Buckingham, Bedford, Huntingdon, and Ely, discharging itself into the bay of the German sea at Lynn.

OUSTIACH, or **Ostiach Country**, is a part of Asiatic Russia, extending along the river Irtyz to its confluence with the river Obys, and from thence northward along the banks of the Obys and Jenisa, into the gulph of the Mangazea, or the frozen ocean; and extending also along

the banks of several rivers which fall into the Obi and Jenisa.

OUTLAW, signifies one that is deprived of the benefit of the law, and therefore held to be out of the king's protection. See the next article.

OUTLAWRY, is where a person is outlawed, and on that account loses the benefit of a subject.

The process of outlawry lies in indictments of treason or felony, and also of trespass vi & armis, conspiracy, &c. And by statute, persons may be outlawed in many civil actions, as debt, case, covenant, &c.

OUTWORKS, in fortification, all those works made without side the ditch of a fortified place, to cover and defend it. See **FORTIFICATION**.

OUZEL in ornithology. See **MOTACILLA**.

OWL, in ornithology. See **STRIX**.

OX, in zoology. See **Bos**.

OXALIS, in botany, a genus of the decandria pentagynia class. The calix consists of five leaves; the petals are connected by the claws; and the capsule has five sides. There are 14 species, only one of them, *viz.* the acetosella, or wood sorrel, is a native of Britain.

OXFORD, the capital of Oxfordshire, and the see of a bishop; it is situated at the confluence of the Isis and Cherwell, fifty-five miles west of London: W. long. 1° 15', and N. lat. 51° 45'.

Oxford is most remarkable on account of its university, which consists of twenty colleges and five halls: this city sends two members to parliament, and the university as many.

OXGANG, or **OXGATE**, is generally taken, in our old law-books, for fifteen acres, or as much ground as a single ox can plough in a year.

OXUCLÆ, in natural history, the name of a genus of fossils of the class of the selenitæ, but of the columnar, not the rhomboidal kind.

Of this genus there are only two known species. 1. A fine kind, with thin flakes and transverse filaments, found in the clayey banks of the river Nen, near Peterborough, in Northamptonshire; and, 2. A dull kind, with thick plates and longitudinal filaments. This is not uncommon in Yorkshire, and lies sometimes in a yellow, sometimes in a blue clay.

OXUS, a river which rises in the mountains on the north of India; and running north-west, through Ubec Tartary, afterwards separates Persia from Ubec Tartary, and falls into the Caspian sea, in 44° N. lat.

XYCOCCUS, in botany. See **VACCINIUM**.

OXYCRATE, in pharmacy, &c. a mixture of vinegar and water, proper to assuage, cool, & all refresh: they make fomentations of oxycrate, clysters of oxycrate, &c. The usual proportion is one spoonful of vinegar to five or six spoonfuls of water.

OXYCROCEUM, in pharmacy, &c. a preparation much used in plasters for fractures, &c. made as follows: Take yellow wax, one pound; pitch and galbanum, each half a pound: melt them over a gentle fire; and then add of Venice-turpentine, myrrh, and oil-banum, each three ounces; fasson, two ounces: make them into a plaster.

XYGLYCU, a species of drink prepared of the sweetest honey combs, macerated and boiled. The combs from which all the honey has been expressed, are put into a pot with pure water, and boiled till they seem to have deposited all their contained honey in the water. This liquor is to be kept, and, when diluted with cold water, is to be drank in the summer-time, in order to remove thirst.

OXYMEL, in pharmacy, a composition of vinegar and honey.

There are several sorts of oxymel, whereof the simple kind is made by boiling, in a glazed earthen vessel, and with a gentle fire, two pounds of clarified honey, in a pint of vinegar, to the consistence of a syrup.

OYER, in law-books, seems to have been anciently used for what is now called assize.

OYER and TERMINER, a commission directed to the judge of assize, and other gentlemen, empowering them to hear and determine all criminal causes, and to try all offenders, whether for treason, felony, or trespass.

OYES, or **OYEZ**, signifies *Hear ye*; and is frequently used by the criers in our courts, on making proclamations, or to enjoin silence.

OYSTER, in zoology. See **OSTREA**.

OZÆNA, a foul and malignant ulcer of the nose, distinguished by its fetor, and often accompanied with a caries of the bones of the nose.

P.

P A C

PABULUM. See **FUEL** and **FIRE**.

PACA, in zoology. See **MUS**.

PACE, a measure taken from the space between the two feet of a man, in walking; usually reckoned two feet and a half, and in some men a yard or three feet.

The geometrical pace is five feet; and 60000 such paces make one degree of the equator.

PACE, in the manege, is of three kinds, *viz.* walk, trot, and gallop; to which may be added an amble, because some horses have it naturally.

P A C

Horses which go shuffling or mixed paces, between the walk and amble, are for the most part of no value; which commonly proceeds from their fiery temper, and sometimes from a weakness in their reins or legs.

PACHAMAC, a temple of Peru, in South America, dedicated by the Indians to the supreme being: it gives its name to the adjacent country.

PACHODECARHOMBIS, in natural history, the name of a genus of fossils, of the class of the selenitæ, expressing a thick rhomboidal body, composed of ten planes.

PACIFIC

PACIFIC OCEAN, that vast ocean which separates Asia from America: it is called Pacific, from the moderate weather the first mariners who sailed in it met with between the tropics; and it was called south-sea, because the Spaniards crossed the isthmus of Darien from north to south, when they first discovered it: though it is properly the Western ocean, with regard to America.

PACK, in commerce, denotes a quantity of goods, made up in loads, or bales, for carriage.

A pack of wool is seventeen stone and two pounds, or a horse's load.

PACKAGE, is a small duty of one penny in the pound, paid for all goods not particularly rated.

PACOS, in zoology. See **CAMELUS**.

PACTOLUS, a river of Lydia in the lesser Asia, celebrated by the ancient poets for its golden sands.

PADDOC, or **PADDOU-COURS**, a piece of ground encompassed with pales or a wall, and taken out of a park for exhibiting races with grey-hounds, for plates, wagers, or the like.

PADERBORNE, the capital of the bishopric of the same name in Westphalia: E. long. 8° 25', N. lat. 51° 45'.

PADSTOW, a market town of Cornwall, thirty miles west of Launceston.

PADUA, the capital of the Paduan, in Italy, a city of a circular form, situated twenty-two miles west of Venice: E. long. 12° 15', N. lat. 45° 30'.

PADUAN, a province of Italy, in the territories of Venice, thirty-five miles long, and almost as much in breadth; bounded by the Trevisanè on the north, by the duchy of Venice on the east, by the Polesin de Rovigo on the south, and by the Vicentin on the west.

PADUAN, among the medalists, a modern medal struck in imitation of the antique; or a new medal struck with all the marks and characters of antiquity.

PADUS, in botany. See **PRUNUS**.

PEAN, among the ancient pagans, was a song of rejoicing sung in honour of Apollo, chiefly used on occasions of victory and triumph.

PEAN, in the ancient poetry, a foot consisting of four syllables; of which there are four kinds, the *pean primus*, *secundus*, &c.

The *pean primus* consists of one long syllable and three short ones, or a trocheus and pyrrhichius, as *temporibus*; the *pean secundus* consists of a short syllable, a long, and two short, or an iambus and a pyrrhichius, as *potentia*; the *pean tertius* consists of two short syllables, a long and a short one, or a pyrrhichius and a trocheus, as *animatus*; the *pean quartus* consists of three short syllables and a long one, or a pyrrhichius and iambus, as *celeritas*.

PÆDEROTA, in botany, a genus of the diandria monogynia class, of which there are two species, none of them natives of Britain.

PÆDO-BAPTISM, infant-baptism, or that conferred on children.

PÆONTIA, in botany, a genus of the polyandria digynia class. The calix consists of five leaves, and the corolla of five petals; the stylus is wanting; and the capsule contains many seeds. There are two species, none of them natives of Britain.

The root of this plant is a very celebrated medicine in nervous cases.

PAGAN, a heathen, gentile, or idolater; one who adores false gods. See **MYTHOLOGY**.

PAGANALIA, certain festivals observed by the ancient Romans in the month of January. They were instituted by Servius Tullius, who appointed a certain number of villages (*pagi*), in each of which an altar was to be raised for annual sacrifices to their tutelar gods; at which all the inhabitants were to assist, and give presents in money, according to their sex and age, by which means the number of country-people was known. The servants upon this occasion offered cakes to Ceres and Tellus, to obtain plentiful harvests.

PAGANELLUS, in ichthyology. See **GORIUS**.

PAGANISM, the religious worship and discipline of pagans; or, the adoration of idols and false gods. See **IDOLATRY** and **MYTHOLOGY**.

PAGEANT, a triumphal car, chariot, arch, or other like pompous decoration, variously adorned with colours, flags, &c. carried about in public shews, processions, &c.

PAGOD, or **PAGODA**, a name whereby the East-Indians call the temple in which they worship their gods.

PAGOD, or **PAGODA**, is also the name of a gold and silver coin, current in several parts of the East-Indies.

PAIN, is defined to be an uneasy sensation arising from a sudden and violent solution of the continuity, or some other accident in the nerves, membranes, vessels, muscles, &c. of the body; or, according to some, it consists in a motion of the organs of sense; and, according to others, it is an emotion of the soul occasioned by these organs.

PAINTING, the art of representing natural bodies, and giving them an appearance of life, by the turn of lines, and the degrees of colours.

Whoever would apply himself to painting, says Leonardo da Vinci, must in the first place learn perspective: this will enable him to dispose things in their proper places, and to give the due dimensions to each: having done this, he must learn to design; chusing for that purpose some able master, who at the same time may give him some insight into the colours of figures: he ought then to consult nature, to confirm himself in what he has already learnt; and, lastly, let him apply himself to the study and imitation of the greatest masters, in order to get a habit of reducing what he has learnt into practice.

To judge of the goodness of a painting, it is necessary to establish to ourselves a system of rules to be applied occasionally; and to assist the judgment herein, the following rules have been laid down: 1. The subject must be finely imagined, and, if possible, improved in the painter's hands; he must think well as an historian, poet, philosopher, or divine, and more especially as a painter, in making a wise use of all the advantages of his art, and in finding expedients to supply its defects. 2. The expression must be proper to the subject, and the characters of the persons: it must be strong, so that the dumb shew may be perfectly and readily understood: every part of the picture must contribute to this end; colours, animals, draperies, and especially the actions of the figures, and above all the airs of the heads. 3. There must be one principal light; and this, and all the subordinate ones, with the shadows and repotes, must make one entire and harmonious mass; the several parts must be well connected and contrasted, so as to render the whole as grate-
ful

to the eye; as a good piece of music to the ear. By this means the picture is not only more delightful, but better seen and comprehended. 4. The drawing must be just; nothing must be flat, lame, or ill proportioned; and these proportions should vary according to the characters of the persons drawn. 5. The colouring, whether gay or solid, must be natural, beautiful, and clean, and what the eye is delighted with, in shadows, as well as lights and middle tints; and whether the colours are laid on thick, or finely wrought, they must appear to be done by a light and accurate hand. Lastly, Nature must be the foundation that must be seen at the bottom; but nature must be raised and improved, not only from what is commonly seen, to what is but rarely met with, but even yet higher, from a judicious and beautiful idea in the painter's mind, so that grace and greatness may shine through better more or less according to the subject.

Painting is of various kinds, according to the materials used, the matter upon which they are applied, and the manner of applying them; as painting in oil, in water-colours, fresco, &c.

PAINTING in oil. The whole secret of painting in oil consists in grinding the colours with nut oil, or linseed-oil; but the manner of working is very different from that in fresco, or in water, by reason the oil does not dry near so fast, which gives the painter an opportunity of touching and re-touching all the parts of his figures as often as he pleases; which in the other methods of painting is a thing impracticable. The figures done in oil are also capable of more force and boldness; inasmuch that the black becomes blacker, when ground with oil, than with water; besides, all the colours mixing better together, makes the colouring the sweeter, more delicate and agreeable, and gives an union and tenderness to the whole, inimitable in any of the other manners.

Painting in oil is performed on canvas, on walls, wood, stone, and all sorts of metals. 1. Painting on cloth or canvas is done as follows: The canvas being stretched on a frame, give it a layer of size, or paste-water, and then go over it with a pumice-stone to smooth off the knots. By means of the size, the little threads and hairs are all laid close on the cloth, and the little holes filled up, so that no colour can pass through. When the cloth is dry, lay on oker in oil, which may be mixed with white-lead to make it dry the sooner. When dry, go over it again with the pumice-stone, to make it smooth. After this a second couch is sometimes applied, composed of white-lead and a little charcoal-black, to render the ground of an ash colour. Others prime the canvas in the following manner: They first smooth the canvas with a pumice-stone, size it over with a good size and a little honey, and let it stand to dry; after which they lay it over with whitening and size, mixed with a little honey: the use of the honey is to prevent it from cracking, peeling, and breaking out; on this they first draw the picture with a coal, and then lay on the colours. 2. Painting on walls: When the wall is dry, they give it two or three washes with boiling oil; till the plaster remains quite greasy, and will imbibe no more; upon this they lay drying colours, such as white-chalk, red-oker, or other chalks beaten pretty stiff. When this couch or layer is well dried, the subject or design is sketched out, and afterwards painted over, mixing a little varnish with their colours, to save the varnishing afterwards. In order the

better to fortify the wall against moisture, some cover it with a plaster of lime, marble-dust, or a cement made of beaten tiles soaked in linseed-oil; and at last prepare a composition of green-pitch, mastic, and thick varnish boiled together, which they apply hot over the former plaster; and when dry, lay on the colours as before. Others, in fine, make their plaster with lime-mortar, tile-cement, and sand; and this being dry, they apply another of lime, cement, and iron scorie; which being well beaten, and incorporated with linseed-oil and whites of eggs, makes an excellent plaster. When this is dry, the colours are laid on as before. 3. In painting on wood, they usually give their ground a couch or layer of white tempered with size, and then proceed as in painting on walls. 4. In painting on stone or metals, it is not necessary to lay them over with size, but only to add a slight couch of colours before the design is drawn on it; nor even is this done on stones, where you would have the ground appear, as in certain marbles and agates of extraordinary colours.

All the colours used in fresco are good in oil, except white of lime and marble dust. Those chiefly used are white-lead, or ceruse, yellow and white mastic, orpiment, vermilion, lacca, blue and green albes, verdigraese, indigo, smalt, black-lead, ivory-black, lamp-black, &c. As to oils, the best are those of linseed, walnuts, spike, and turpentine. The drying oils are nut-oil, boiled with litharge and sandarach, and otherwise with spirit of wine, mastic, and gum-lacca.

In the preparation of oil-colours, care must be taken that they be ground fine; that in putting them on a pallet, those which will not dry of themselves be mixed with drying oil, or other ingredients of a drying quality; and that the tinged colours be mixed in as small quantities as possible. As to the situation of the colours, the purest and strongest must be placed in the front of the piece, and the colouring varied according to the subject, time, and place. If the subject be grave, melancholy, or terrible, the general tint of the colouring must incline to brown and black, or red and gloomy; but it must be gay and pleasant, in subjects of joy and triumph.

PALÆSTRA, in Grecian antiquity, a public building, where the youth exercised themselves in wrestling, running, playing at quoits, &c.

PALÆSTROPHYLAX, was the director of the palæstra and the exercises performed there.

Sr. PALAIS, a town of France, in the province of Gascony, capital of the lower Navarre, situated in W. long. 1° 8', N. lat. 43° 23'.

PALAMBANG, or **PALAMBANG**, the capital of a kingdom at the east end of the island of Java, in the East-Indies, situated on the straits of Bally, in E. long. 114°, S. lat. 7° 30', and separated from the island of Bally by a narrow strait.

PALAMEDIA, in ornithology, a genus belonging to the order of grallæ. The bill is conical, the superior mandible being crooked; and the feet have three divided toes.

There are two species, both natives of Brasil.

PALARIA, among the Romans, a kind of exercise performed at a stake by the soldiers. The stake being fixed in the ground, and six feet high above it, the young undisciplined soldiers advanced against it, armed with a hurdle and cudgel, instead of a shield and sword, and went through all the rules of attack and defence, as if actually engaged.

engaged with an adversary. Sometimes they flood at a distance, and attacked with missile weapons, at the same time using all the requisite motions for defending themselves, and warding off what might be thrown against them.

PALATE, in anatomy. See **ANATOMY**, p. 162, 303.
PALATINATE, a province, or signiory, possessed by a palatine.

PALATINE, or **COUNT PALATINE**, a title anciently given to all persons who had any office or employment in the prince's palace; but afterwards conferred on those delegated by princes to hold courts of justice in the provinces; and on such among the lords as had a palace, that is, a court of justice, in their own houses.

At present the word palatine is restrained to a prince of Germany, or a lord of Poland, possessed of a palatine.

PALATO-SALPINGEUS. See **ANATOMY**, p. 303.

PALATO-STAPHYLINUS, in anatomy. See **ANATOMY**, p. 303.

PALÉ, a little pointed stake or piece of wood, used in making inclosures, separations, &c. The pale was an instrument of punishment and execution among the ancient Romans, and still continues to among the Turks. Hence empaling, the passing a sharp pale up the fundament through the body.

PALÉ, in heraldry, one of the honourable ordinaries of an escutcheon; being the representation of a pale or stake placed upright, and comprehending the whole height of the coat from the top of the chief to the point. When the pale is single, it is to contain one third of the breadth of the shield. See **PLATE CXXXIV. fig. 7.**

PALERMO, the capital of the island of Sicily, situated on the north coast of that island, on a bay of the Mediterranean sea: in E. long. 15°, N. lat. 38° 30'.

PALESTINE, a part of Asiatic Turkey, situated between thirty-six and thirty-eight degrees of east longitude, and between thirty-one and thirty-four degrees of north latitude: it is bounded by Mount Libanus, which divides it from Syria, on the north; by Mount Hermon, which separates it from Arabia Deserta, on the east; by the mountains of Seir and the Deserts of Arabia Petrea, on the south; and by the Mediterranean sea, on the west.

It was called Palestine, from the Philistines who inhabited the sea-coasts. It was also called Judea, from Judah; and the Holy Land, from our Saviour's residence and sufferings in it; and it is called Canaan, and the Promised Land, in the scriptures.

It is 150 miles in length, and 80 in breadth; and in the time of Solomon it seems to have extended from the Mediterranean sea to the river Euphrates.

PALESTRINA, a city of Italy, in the pope's territory and Campania of Rome, situated thirty miles east of Rome.

PALIMBAM, a town on the island of Sumatra, in the East-Indies, situated in E. long. 103°, S. lat. 3°.

PALINDROMUS, a verse or sentence which runs the same when read either backwards or forwards; such is the verse,

Roma tibi subito motibus ibit amor.

PALING, a sort of fencing for fruit-trees planted in fields, wherein three small posts are erected at a foot and a half distance one from another, and near the top nailed to each other with cross-bars.

VOL. III. N°. 87.

5 X

+

PALMISTRY,

PALINGENESIA, among divines, signifies the same with regeneration.

Among chemists, it denotes the producing a body from its principles.

PALINODY, a discourse contrary to a preceding one: hence the phrase *palinodiam canere* was taken for a recantation.

PALISADE, in fortification, an inclosure of stakes or piles driven into the ground, each six or seven inches square, and eight feet long, three whereof are hid under ground.

PALISSE, in heraldry, a bearing like a range of palisades before a fortification, represented on a fesse, rising up a considerable height, and pointed a-top, with the field appearing between them. See **PLATE CXXXIV. fig. 8.**

PALIURUS, in botany. See **RHAMNUS**.

PALL, in heraldry, denotes a kind of cross representing the pallium, or archiepiscopal ornament sent from Rome to the Metropolitans. See **PLATE CXXXIV. fig. 9.**

PALLA, in Roman antiquity, a mantle which women wore over the gown called stola. It was borne on the left shoulder; whence passing to the other side, under the right arm, the two ends were bound under the left arm, leaving the breast and arm quite bare.

PALLADIUM, in antiquity, a statue of the goddess Pallas, supposed to have dropped down from heaven, preserved in Troy, whereon the fate of that city is said to have depended.

PALLET, among painters, a little oval table, or piece of wood, or ivory, very thin and smooth; on and round which the painters place the several colours they have occasion for, to be ready for the pencil. The middle serves to mix the colours on, and to make the tints required in the work. It has no handle, but instead thereof, a hole at one end to put the thumb through to hold it.

PALLET, in heraldry, is nothing but a small pale, consisting of one half of it in breadth, and therefore there are sometimes several of them upon one shield.

PALLET, in ship-building, is a room within the hold, closely parted from it, in which by laying some pigs of lead, &c. a ship may be sufficiently ballasted, without losing room in the hold; which, therefore, will serve for the stowing the more goods.

PALLIATION, or **PALLIATIVE CURE**, in medicine, is when, in desperate and incurable diseases, after predicting the fatal event, the physician prescribes some remedies for mitigating the pain or some other urgent symptoms, as in ulcerated cancers, or cancerous fistulas, and the like.

PALLIUM, or **PALT**, an archiepiscopal vestment, of white woollen cloth, about the breadth of a border, made round, and thrown over the shoulders.

PALMSUNDAY, in the Christian church, the Sunday next before Easter; being so called in memory of our Saviour's triumphal entry into Jerusalem, when the multitude that attended him strewed palm-branches in his way.

PALM-TREE, in botany. See **PHOENIX**.

PALMA-ISLE, one of the Canary-islands, sixty miles north-west of Teneriff.

PALMARIS, in anatomy. See **ANATOMY**, p. 199.

PALMATED, something resembling the shape of the hand: thus we say palmated leaves, roots, stones, &c.

PALMIPEDES, among ornithologists, the same with web-footed birds.

PALMISTRY, a kind of divination, or rather a deceitful art practised by gypsies, who pretend to foretell events by looking upon the lines and marks of the hand.

PALMYRA, the ruins of a magnificent city, in the province of Syria, two hundred miles south-east of Aleppo.

PALOS, a port-town of Spain, situated on the bay of Cadiz: W. long. $7^{\circ} 15'$, N. lat. 37° .

PALPABLE, something perceivable by the senses, particularly that of feeling.

PALPITATION, a spasmodic contraction of the heart, when it leaps and beats violently.

PALSY, in medicine. See **MEDICINE**, p. 97.

PALUDAMENTUM, in Roman antiquity, a habit that differed in little from the chlamys, except that this last belonged chiefly to the lower class of people. See **CHLAMYS**.

PALUMBUS. See **COLUMBA**.

PALY, or **PALÉ**, in heraldry, is when the shield is divided into four or more equal parts, by perpendicular lines falling from the top to the bottom. See Plate CXXXIV. fig. 1c.

Paly bendy is when the escutcheon is divided by perpendicular lines, which is paly; and also by diagonals, which is called bendy. See the article **BENDY**.

PAMPELUNA, the capital of Spanish Navarre, is the see of a bishop, and an university: W. long. $1^{\circ} 30'$, N. lat. $43^{\circ} 15'$.

PANACEA, among physicians, denotes an universal medicine, or a remedy for all diseases; a thing impossible to be obtained.

PANADA, a diet consisting of bread boiled in water to the consistence of a pulp, and sweetened with a little sugar.

PANAMA, the capital city of the province of Darien, in South America, where the treasures of gold and silver, and the other rich merchandize of Peru, are lodged in magazines till they are sent to Europe: W. long. 82° , N. lat. 9° .

PANARO, a river of Italy, which rising in the Apennine mountains, on the confines of Tuscany, divides Modena from Romania, and then running through the Ferrarese falls into the Gulph of Venice.

PANATHENÆA, in Grecian antiquity, an ancient Athenian festival, in honour of Minerva, who was the protectress of Athens, and called Athena.

PANAX, in botany, a genus of the polygamia dioecia class. The calix of the hermaphrodite has five teeth, and the corolla five petals; there are five stamina, and two stamyls; and the berry contains two seeds. The calix of the male is entire; the corolla has five petals; and there are five stamina. The species are three, none of them natives of Britain.

PANAY, the capital of the isle of Panay, one of the Philippine islands: E. long. 119° , and N. lat. 11° .

PANCARPUS, in Roman antiquity, a kind of shew which the Roman emperors frequently exhibited to the people. In this spectacle, the circus being set all over with large trees, represented a forest, into which the beasts being let from the dens under the ground, the people, at a sign given by the emperor, pursued, shot, cut in pieces, and killed all they could lay hold of, which they afterwards carried away, to regale upon at home. The beasts usually given on these occasions were boars, deer, oxen, and sheep.

PANCHYMAGOGUE, in pharmacy, a name given to some cathartic extracts.

PANCRATIUM, among the ancients, a kind of exercise, which consisted of wrestling and boxing. In these contests it was customary for the weaker party, when he found himself pressed by his adversary, to fall down, and fight rolling on the ground.

PANCRATIUM, in botany, a genus of the hexandria monogynia class. It has six petals, and a nectarium divided into twelve segments, and the stamina lie upon the nectarium. There are seven species, none of them natives of Britain.

PANCREAS, in anatomy. See **ANATOMY**, p. 265.

PANDECTS, in the civil law, collections made by Justinian's order, of five hundred and thirty-four decisions of the ancient lawyers, on so many questions occurring in the civil law; to which that emperor gave the force and authority of law, by an epistle prefixed to them. The pandects consist of fifty books, and make the first part of the body of the civil law.

PANDICULATION, a stretching, or that violent and tense motion of the solids, which usually accompanies the act of yawning.

PANEGYRIC, an oration in praise of some extraordinary thing, person, or virtue.

Panegyrics were anciently made in the public and solemn assemblies of the Greeks, either at their games, their feasts, or religious meetings.

PANEGYRICUM, in church-history, an ecclesiastical book, used by the Greek church, containing the panegyric orations of various authors on the solemnities of Jesus Christ and the saints.

PANGONIA, in natural history, the name of a genus of crystal, consisting of such as are composed of many angles.

PANIC, denotes an ill-grounded terror or fright.

PANICLE, in botany, denotes a soft woolly beard, on which the seeds of some plants, as millet, reeds, &c. hang.

PANICUM, in botany, a genus of the triandria digynia class. The calix consists of three valves, the inmost of which is least. There are 28 species, four of which are natives of Britain, viz. the viride, or green panic-grass; the crusgalli, or loose panic-grass; the sanguinale, or cock's-foot panic-grass; and the dactylon, or creeping panic-grass.

PANNEL, in law, signifies the prisoner at the bar, or person who takes his trial before the court of judicature, for some crime. See **LAW**, Tit. xxxiii. 47.

PANNELS of a saddle, are two cushions or bolsters, filled with cow's, deer's, or horse-hair, and placed under the saddle, on each side, to prevent the bows and bands from galling the horse.

PANNICULUS CARNOSUS, in comparative anatomy, a robust fleshy tunic, situated in beasts, between the tunic and the fat; by means of which they can move their skin in whole or part: it is altogether wanting in mankind.

PANORPA, the **SCORPION-FLY**, in zoology, a genus of insects belonging to the order of neuroptera. The rostrum is horny and cylindrical; there are two pappi, and three stemonata; the feelers are longer than the thorax; and the tail of the male is furnished with a forceps. There are four species, distinguished by the colour and shape of their wings.

PANTALOOM

PANTALOON, a sort of garment, consisting of breeches and stockings all of one piece; said to have been first introduced by the Venetians.

PANTHEON, in Roman antiquity, a temple of a circular form, dedicated to all the gods: It was built by Agrippa, son-in-law to Augustus; but is now converted into a church, and dedicated to the Virgin and all the martyrs.

PANTHER, in zoology. See **LEO**.

PANTOMIME, a person who imitates all sorts of actions and characters, by mere gestures, without speaking a word.

PANUCO, a city of Mexico, situated at the mouth of a river of the same name, and which falls into the gulf of Mexico: W. long. 103°, and N. lat. 23°.

PAPAYER, in botany, a genus of the polyandria monogynia class. The corolla consists of four petals, and the calix of two leaves. There are nine species, six of them natives of Britain, *viz.* the hybridum, or round rough-headed poppy; the cambricum, or yellow poppy; the somniferum, or wild poppy; the ergemone, or long rough-headed poppy; the rhæas, or red corn-poppy; and the dubium, or long smooth-headed poppy. For the medical properties of poppy, see **OPIMUM**.

PAPENHEIM, a town of Franconia, in Germany, subject to its own count: E. long. 11°, N. lat. 48° 55'.

PAPER, sheets of a thin matter, made of some vegetable substance.

The materials on which mankind have, in different ages, contrived to write their sentiments, have been extremely various; in the early ages they made use of stones, and tables of wood, wax, ivory, &c. See **BOOK**.

Paper, with regard to the manner of making it, and the materials employed therein, is reducible to several kinds; as Egyptian paper, made of the rush papyrus; bark-paper, made of the inner rind of several trees; cotton paper; incombustible paper; and European paper, made of linen-rags.

Egyptian paper was principally used among the ancients; being made of the papyrus, or biblus, a species of rush which grew on the banks of the Nile. In making it into paper, they began with lopping off the two extremes of the plant, the head and the root; the remaining part, which was the stem, they cut lengthwise into two nearly equal parts, and from each of these they stripped the scaly-pellicles of which it consisted. The innermost of these pellicles were looked on as the best, and that nearest the rind as the worst: they were therefore kept apart, and made to constitute two different sorts of paper. As the pellicles were taken off, they extended them on a table, laying them over each other transversely, so as that the fibres made right angles: in this state they were glued together by the muddy waters of the Nile; or, when those were not to be had, with paste made of the finest wheat-flour mixed with hot water and a sprinkling of vinegar. The pellicles were next pressed to get out the water, then dried, and lastly flattened and smoothed by beating them with a mallet: this was the Egyptian paper, which was sometimes farther polished by rubbing it with a glass-ball, or the like.

Bark-paper was only the inner whitish rind, inclosed between the bark and the wood of several trees, as the maple, plane, beech, and elm, but especially the tilia, or Linden-tree, which was that mostly used for this purpose.

On this stripped off, flatted, and dried, the ancients wrote books, several of which are said to be still extant.

Chinese paper is of various kinds. Some is made of the rinds or barks of trees, especially the mulberry-tree and elm, but chiefly of the bambu and cotton-tree. In fact, almost each province has its several paper. The preparations of paper made of the barks of trees, may be instanced in that of the bambu, which is a tree of the cane or reed kind. The second skin of the bark, which is soft and white, is ordinarily made use of for paper: this is beat in fair water to a pulp, which they take up in large moulds, so that some sheets are above twelve feet in length; they are completed, by dipping them sheet by sheet, in alum-water, which serves instead of the size among us, and not only hinders the paper from imbibing the ink, but makes it look as if varnished over. This paper is white, soft, and close, without the least roughness; though it cracks more easily than European paper, is very subject to be eaten by the worms, and its thinness makes it liable to be soon worn out.

Cotton paper is a sort of paper which has been in use upwards of six hundred years. In the French king's library are manuscripts on this paper, which appear to be of the Xth century; and from the XIIth century, cotton manuscripts are more frequent than parchment ones. Cotton-paper is still made in the East-Indies, by beating cotton-rags to a pulp.

Linen or European paper appears to have been first introduced among us towards the beginning of the XIVth century; but by whom this valuable commodity was invented, is not known. The method of making paper of linen or hempen-rags, is as follows. The linen-rags being carried to the mill, are first sorted, then washed very clean in puncheons, whose sides are grated with strong wires, and the bottoms bored full of holes. After this they are fermented, by laying them in heaps close covered with sack, till they sweat and rot, which is commonly done in four or five days. When duly fermented, they are twisted into handfuls, cut small, and thrown into oval mortars, made of well-seasoned oak, about half a yard deep, with an iron-plate at bottom, an inch thick, eight inches broad, and thirty long; in the middle is a washing-block, grooved, with five holes in it, and a piece of hair-sieve fastened on the inside; this keeps the hammers from touching it, and prevents any thing going out except the foul water. These mortars are continually supplied with water, by little troughs from a cistern, fed by buckets fixed to the several floots of a great wheel, which raises the wooden hammers for pounding the rags in the mortars. When the rags are beaten to a certain degree, called the first stuff, the pulp is removed into boxes, made like corn-chandlers bins, with the bottom-board afloat, and a little separation on the front for the water to drain away. The pulp of the rags being in, they take away as many of the front boards as are needful, and press the mass hard down with their hands; the next day they put on another board, and add more pulp, till the box is full; and here it remains mellowing a week, more or less, according to the weather. After this, the stuff is again put into clean mortars, and is beaten afresh, and removed into boxes, as before, in which state it is called the second stuff. The mass is beat a third time, till some of it being mixed with fair water, and brewed to and fro,

appears

appears like flour and water, without any lumps in it: it is then fit for the pit-mortar, where it is perfectly dissolved, and is then carried to the vat, to be formed into sheets of paper. But lately, instead of pounding the rags to a pulp with large hammers, as above, they make use of an engine, which performs the work in much less time. This engine consists of a round solid piece of wood, into which are fastened several long pieces of steel, ground very sharp. This is placed in a large trough with the rags, and a sufficient quantity of water. At the bottom of the trough is a plate with steel bars, ground sharp like the former; and the engine being carried round with prodigious velocity, reduces the rags to a pulp in a very short time. It must be observed, that the motion of the engine causes the water in the trough to circulate, and by that means constantly returns the stuff to the engine. The trough is constantly fed with clean water at one end, while the dirty water from the rags is carried off at the other, through a hole, defended with wire gratings, in order to hinder the pulp from going out with the dirty water.

When the stuff is sufficiently prepared as above, it is carried to the vat, and mixed with a proper quantity of water, which they call priming the vat. The vat is rightly primed, when the liquor has such a proportion of the pulp, as that the mould, on being dipped into it, will just take up enough to make a sheet of paper of the thickness required. The mould is a kind of sieve exactly of the size of the paper to be made, and about an inch deep, the bottom being formed of fine brass wire, guarded underneath with sticks, to prevent it bagging down, and to keep it horizontal; and further, to strengthen the bottom, there are large wires placed in parallel lines, at equal distances, which form those lines visible in all white paper when held up to the light: the mark of the paper is also made in this bottom, by interweaving a large wire in any particular form. This mould the maker dips into the liquor, and gives it a shake as he takes it out, to clear the water from the pulp. He then slides it along a groove to the coucher, who turns out the sheet upon a felt laid on a plank, and lays another felt on it; and returns the mould to the maker, who by this time has prepared a second sheet in another mould: and thus they proceed, laying alternately a sheet and a felt, till they have made six quires of paper, which is called a post; and this they do with such swiftness, that, in many forts of paper, two men make twenty posts, or more in a day. A post of paper being made, either the maker or coucher whistles; on which four or five men advance, one of whom draws it under the press, and the rest press it with great force, till all the water is squeezed from it; after which it is separated sheet by sheet from the felts, and laid regularly one sheet upon another; and having undergone a second pressing, it is hung up to dry. When sufficiently dried, it is taken off the lines, rubbed smooth with the hands; and laid by till sized, which is the next operation. For this they chuse a fine temperate day; and having boiled a proper quantity of clean parchment, or vellum shavings, in water, till it comes to a size, they prepare a fine cloth, on which they strew a due proportion of white vitriol and rock-alum finely powdered, and strain the size through it into a large tub; in which they dip as much paper at once as they can conveniently

hold, and with a quick motion give every sheet its share of the size, which must be as hot as the hand can well bear it. After this, the paper is pressed, hung up sheet by sheet to dry; and being taken down, is sorted, and what is only fit for outside-quires laid by themselves: it is then told into quires, which are folded and pressed. The broken sheets are commonly put together, and two of the worst quires are placed on the outside of every ream or bundle; and being tied up in wrappers, made of the setting of the vat, it is fit for sale.

Paper is of various kinds, and used for various purposes: with regard to colour, it is principally distinguished into white, blue, and brown; and with regard to its dimensions, into atlas, elephant, imperial, super-royal, royal, medium, demy, crown, foolscap, and pot-paper. **PAPER-OFFICE**, an office in the palace of Whitehall, in which all the public writings, matters of state and council, proclamations, letters, intelligences, negotiations abroad, and generally all dispatches that pass through the offices of the secretaries of state, are lodged, by way of library. **PAPHLAGONIA**, an ancient province of the lesser Asia, situated on the Euxine sea, now part of the province of Amasia in Turkey.

PAPHOS, once an elegant city at the west end of the island of Cyprus; but the little town of Baffo is now all that remains of it.

PAPILIO, the **BUTTERFLY**, in zoology, a genus of insects belonging to the order of lepidoptera. It has four wings, imbricated with a kind of downy scales; the tongue is convoluted in a spiral form; and the body is hairy. There are 273 species, principally distinguished by the colour of their wings.

PAPILIONACEOUS, among botanists, an appellation given to the flowers of plants belonging principally to the diadelphia class, from their resembling the figure of a butterfly.

PAPOUS, or **NEW GUINEA**, a large continent in the Pacific ocean, a little south of the equator; situated east of the Spice islands, in 120° east long. but how far it extends farther to the eastward or southward, is uncertain.

PAPPUS, in botany, a soft downy substance, that grows on the seeds of certain plants, as thistles, hawkweed, &c. serving to scatter and buoy them up in the air.

PAR, in commerce, signifies any two things equal in value. See **COMMERCE**.

PARABLE, a fable, or allegorical instruction, founded on something real or apparent in nature or history, from which a moral is drawn, by comparing it with something in which the people are more immediately concerned; such are the parables of Dives and Lazarus, of the Prodigal Son, of the Ten Virgins, &c.

PARABOLA. See **CONIC SECTIONS**.

PARACENTESIS, an operation in surgery, commonly called tapping. See **SURGERY**.

PARACLET, the **COMFORTER**, a name given to the Holy Ghost.

PARADISEA, in ornithology, a genus belonging to the order of picæ. The beak is covered with a belt or collar of downy feathers at the base; and the feathers on the sides are very long. There are three species, viz. 1. The *æpoda*, has the feathers on the sides longer than the body, and two long bristly feathers in the tail. It is the greater bird of paradise, and feeds upon butterflies. They

are

are found in large flocks in the Molucca islands. 2. The regia, has two intermediate prime tail-feathers like threads and feathery at the points. It is found in Amboina. 3. The triflis, has a naked triangular spot behind the eyes; and the head and neck are of a dusky colour. It is a native of the Philippine isles, and feeds upon grass-hoppers and other insects.

PARADISE, a term principally used for the garden of Eden, in which Adam and Eve were placed immediately upon their creation.

As to this terrestrial paradise, there have been many inquiries about its situation. It has been placed in the third heaven, in the orb of the moon, in the moon itself, in the middle region of the air, above the earth, under the earth, in the place possessed by the Caspian sea, and under the arctic pole. The learned Huetius places it upon the river that is produced by the conjunction of the Tigris and Euphrates, now called the river of the Arabs, between this conjunction and the division made by the same river before it falls into the Persian sea. Other geographers have placed it in Armenia, between the sources of the Tigris, the Euphrates, the Araxis, and the Phasis, which they suppose to be the four rivers described by Moses.

The celestial paradise is that place of pure and refined delight, in which the souls of the blessed enjoy everlasting happiness.

Bird of Paradise. See **PARADISEA**.

PARADOX, in philosophy, a proposition seemingly absurd, as being contrary to some received opinion, but yet true in fact.

No science abounds more with paradoxes than geometry: thus, that a right line should continually approach to the hyperbola, and yet never reach it, is a true paradox; and in the same manner, a spiral may continually approach to a point, and yet not reach it, in any number of revolutions, however great.

PARÆA, in zoology. See **COLUBER**.

PARAGOGE, in grammar, a figure whereby a letter or syllable is added to the end of a word; as *med*, for *me*; *dicier*, for *dict*, &c.

PARAGUAY, or **LA PLATA**, a province of South America; subject to Spain, lies between 12° and 37° S. lat. and between 50° and 75° W. long.

PARALIPOMENA, in matters of literature; denotes a supplement of things omitted in a preceding work.

PARALLACTIC, in general, something relating to the parallax of heavenly bodies. See **PARALLAX**.

PARALLAX, in astronomy. See **ASTRONOMY**, p. 452.

PARALLEL, in geometry, an appellation given to lines, surfaces, and bodies every where equidistant from each other. See **GEOMETRY**.

PARALLELS of latitude, in astronomy, are lesser circles of the sphere parallel to the ecliptic, imagined to pass through every degree and minute of the colures.

PARALLELS of altitude, or **ALMUCANTARS**, are circles parallel to the horizon, imagined to pass through every degree and minute of the meridian between the horizon and zenith, having their poles in the zenith.

PARALLELS of declination, in astronomy, are the same with parallels of latitude in geography.

PARALLEL SPHERE, that situation of the sphere, wherein

the equator coincides with the horizon, and the poles with the zenith and nadir.

PARALLEL SAILING. See **NAVIGATION**.

PARALLELOPPED, in geometry, a regular solid comprehended under six parallelograms, the opposite ones whereof are similar, parallel, and equal.

PARALLELOGRAM, in geometry, a quadrilateral right-lined figure, whose opposite sides are parallel and equal to each other.

PARALLELOPIEDIA, in natural history, the name of a genus of spars, thus called, because regularly of a parallelopped form.

They are pellucid crystalline spars externally of a determinate and regular figure, always found loose, detached, and separate from all other bodies, and in form of an oblique parallelopped, with six parallelogram sides and eight solid angles, easily fissile either in an horizontal or perpendicular direction, being composed of numbers of thin plates, and those of very elegantly and regularly arranged bodies, each of the same form with the whole mass, except that they are thinner in proportion to their horizontal planes; and naturally fall into these and no other figures, on being broken with a slight blow.

PARALOGISM, in logic, a false reasoning, or a fault committed in demonstration, when a consequence is drawn from principles that are false, or, though true, are not proved; or when a proposition is passed over that should have been proved by the way.

PARALYSIS, the **PARSY**. See **MEDICINE**, p. 97.

PARAMECIA, in natural history, a name given to such animalcules as have no visible limbs or tails, and are of an irregularly oblong figure.

PARAMETER, in conic sections, a constant line, otherwise called *latus rectum*. See **CONIC SECTIONS**.

PARAMOUNT, in law, signifies the supreme lord of the fee.

PARANYMPH, among the ancients, the person who waited on the bridegroom, and directed the nuptial solemnities; called also *pronubus*, and *auspex*, because the ceremonies began by taking auspicia. As the paranymp officiated only on the part of the bridegroom, a woman called *pronuba* officiated on the part of the bride.

PARAPET, in fortification, an elevation of earth designed for covering the soldiers from the enemies cannon or small shot. See **FORTIFICATION**.

PARAPHERNAL goods in Scots law. See **LAW**, Tit. vi. 8.

PARAPHIMOSIS, in medicine, a disorder in the penis, wherein the prepuce is shrunk, and withdrawn behind the glans, so as not to be capable of being brought to cover the same; which generally happens in venereal disorders. See **MEDICINE**.

PARAPHRASE, an explanation of some text, in clearer and more ample terms, whereby is supplied what the author might have said or thought on the subject; such are esteemed Erasmus's paraphrase on the New Testament, the Chaldee paraphrase on the Pentateuch, &c.

PARAPHRENTIS, in medicine, an inflammation of the diaphragm. See **MEDICINE**.

PARAPHROSINE, a word used by medical writers to express a delirium, or an alienation of mind in fevers, or from whatever cause.

PARAPLEGIA, a species of palsy. See **MEDICINE**.

PARASELENE, in physiology, a mock moon, a meteor, or phenomenon, encompassing, or adjacent to, the moon, in form of a luminous ring; wherein are sometimes observed one, sometimes two, apparent images of the moon.

PARASITE, among the Greeks, was originally a very reputable title; the parasites being a kind of priests, at least ministers, of the gods, in the same manner as the *Epulones* were at Rome. They took care of the sacred corn, or the corn destined for the service of the temples, and the gods, *viz.* sacrifices, feasts, &c. they had even the intendance over sacrifices, and took care that they were duly performed. At Athens, there was a kind of college of twelve parasites; each people of Attica furnishing one, who was always chosen out of the best families. Polybius adds, that a parasite was also an honourable title among the ancient Gauls, and was given to the poets; but of late it has been made a term of reproach, and used for a flatterer and mean dependant.

PARASITES, or **PARASITICAL PLANTS**, in botany, such plants as are produced out of the trunk or branches of other plants, from whence they receive their nourishment, and will not grow upon the ground, as the mistletoe, &c.

PARASTATÆ, in anatomy. See **ANATOMY**, p. 270.

PARASYNCHE, in medicine, a kind of angina, or quinsy. See **MEDICINE**, p. 84.

PARATHENAR, in anatomy. See **ANAT.** p. 212.

PARBUNDEL, in a ship, the name of a rope almost like a pair of slings: it is seized both ends together, and then put double about any heavy thing that is to be hoisted in or out of the ship; having the hook of the runner hitched into it, to hoist it up by.

PARCÆ, in the heathen mythology, goddesses, who were supposed to preside over the accidents and events, and to determine the date or period, of human life. See **MYTHOLOGY**.

PARCHMENT, the skins of sheep or goats prepared after such a manner as to render it proper for writing upon, covering books, &c.

The manufacture of parchment is begun by the skinner, and finished by the parchment-maker.

The skin having been stripped of its wool, and placed in the lime pit, the skinner stretches it on a kind of frame, and pares off the flesh with an iron instrument: this done, it is moistened with a rag; and powdered chalk being spread over it, the skinner takes a large pumice-stone, flat at bottom, and rubs over the skin, and thus scowers off the flesh: he then goes over it again with the iron instrument, moistens it as before, and rubs it again with the pumice-stone without any chalk underneath: this smooths and softens the flesh-side very considerably. He then drains it again, by passing over it the iron instrument as before. The flesh-side being thus drained, by scraping off the moisture, he in the same manner passes the iron over the wool or hair side: then stretches it tight on a frame, and scrapes the flesh side again: this finishes its draining; and the more it is drained, the whiter it becomes. The skinner now throws on more chalk, sweeping it over with a piece of lamb skin that has the wool on; and this smooths it still farther. It is now left to dry; and when dried, taken off the frame, by cutting it

all round. The skin, thus far prepared by the skinner, is taken out of his hands by the parchment-maker; who first, while it is dry, pares it on a summer (which is a calf skin stretched in a frame) with a sharper instrument than that used by the skinner, and, working with the arm from the top to the bottom of the skin, takes away about one half of its thickness. The skin, thus equally pared on the flesh-side, is again rendered smooth, by being rubbed with the pumice-stone on a bench covered with a sack stuffed with floes, which leaves the parchment in a condition fit for writing upon. The parings thus taken off the leather, are used in making glue, size, &c.

What is called vellum, is only parchment made of the skins of abortives, or at least sucking calves. This has a much finer grain, and is whiter and smoother than parchment; but is prepared in the same manner, except its not being passed through the lime-pit.

PARDALUS. See **LEO**.

PAREGORICS in pharmacy, medicines that assuage pain, otherwise called anodynes.

PAIREIRA BRAVA, in the materia medica, a kind of oblong and large root, brought from the Brasils.

It is certainly a diuretic of no mean character, and has done great service in nephritic cases; and in pleuritis and quinseys it has been attended with more success than almost any medicine we know of singly.

PARELCON, in grammar, a figure by which a word or syllable is added to the end of another.

PAREMBOLE, in rhetoric, a figure wherein something relating to the subject is inserted in the middle of a period. All the differences between the parembole and parenthesis, according to Vossius, is, that the former relates to the subject in hand, whereas the latter is foreign to it.

PARENCHYMA, in anatomy, a term introduced by Erasistratus, signifying all that substance which is contained in the interstices betwixt the blood-vessels of the viscera, which he imagined to be extravasated and concreted blood.

PARENCHYMA of plants. Grew applies the term parenchyma to the pith or pulp, or that inner part of a fruit or plant through which the juice is supposed to be distributed. See **AGRICULTURE**.

PARENT, a term of relation applicable to those from whom we immediately receive our being.

PARENTALIA, in antiquity, funeral obsequies, or the last duties paid by children to their deceased parents.

PARENTHESIS, in grammar, certain intercalary words, inserted in a discourse, which interrupt the sense, or thread, but seem necessary for the better understanding of the subject.

PARENZO, or **PIRENZO**, a port-town of Itria, in the territory of Venice, situated on a bay of the gulph of Venice, twenty-five miles south of Cabo de Itria.

PAREISIS, in medicine, is defined to be a palsy of the bladder, wherein the urine is either suppressed, or discharged involuntarily.

PARETONIUM, in natural history, the name of an earth anciently found on the shores of Egypt, Cyrene, and the island of Crete, and used by the ancients in painting.

PARGET, in natural history, a name given to several kinds of gypsum, or plaster-stone.

PARGETING, in building, is used for the plastering of walls, and sometimes for plaster itself.

PARHELIIUM, or **PARHELION**, in phyfiology, a mock fun, or meteor, in form of a very bright light, appearing on one fide of the fun.

The parhelia are formed by the reflection of the fun's beams on a cloud properly pofited. They ufually accompany the coronæ, or luminous circles, and are placed in the fame circumference and at the fame height. Their colours refemble that of the rainbow, the red and yellow are on the fide towards the fun, and the blue and violet on the other. There are coronæ fometimes feen without parhelia, and *vice verfa*.

Parhelia are double, triple, &c. and in 1629 a parheliion of five funs was feen at Rome, and in 1666 another at Arles of fix.

M. Mariotte accounts for parhelia from an infinity of little particles of ice floating in the air, that multiply the image of the fun by refraction or reflection; and by a geometrical calculus he has determined the precise figure of thefe little icicles, their fituation in the air, and the fize of the coronæ of circles which accompany the parhelia, and the colours wherewith they are painted.

PARIA, a lake of Peru, in South America, in the province of Los Charcas, fited in 67° W. long. and 22° S. lat.

PARIETALIA ossa, in anatomy. See **ANATOMY**, p. 154.

PARIETARIA, in botany, a genus of the polygamia monœcia clafs. The calix, both in the female and hermaphrodite, confifts of four fegments; none of them have any corolla; the hermaphrodite has four ftamina; and both have one ftylus, and one long feed. There are fix fpecies, only one of them, *viz.* the officialis, or pellitory of the wall, is a native of Britain. It is efteemed as cooling and abftergent.

PARIS, in botany, a genus of the oſtandria trigynia clafs. The calix confifts of four leaves, and the corolla of four narrow petals; and the berry has four cells. There is but one fpecies, *viz.* the quadrifolia, herb-paris, or true-love, a native of Britain.

PARIS, in geography, the metropolis of the kingdom of France, and of the principality or government of the ifle of France, fited in E. long. 2° 25', N. lat. 48° 50', two hundred miles fouth-eaft of London, fix hundred and eighty north-eaft of Madrid, five hundred and fifty weft of Vienna, one thouſand three hundred north-weft of Conftantinople, and feven hundred north-weft of Rome.

PARISH, the precinct of a parochial church, or a circuit of ground inhabited by people who belong to one church and are under the particular charge of its miniſter.

PARK, a large incloſure privileged for wild beaſts of chace, either by preſcription or the king's grant.

PARKINSONIA, in botany, a genus of the decandria monogynia clafs. The calix confifts of four fegments, and the corolla of four oval petals, the loweſt being kidney-shaped; it has no ftylus; and the pod is cylindrical.

PARLEY, a conference with an enemy. Hence to beat or found a parley, is to give a ſignal for holding ſuch a conference by beat of drum or found of trumpet.

PARLIAMENT is the grand afſembly of the three ſtates of this kingdom, ſummoned together, by the king's authority, to conſult of matters relating to the public welfare, and particularly to enact and repeal laws. It conſiſts of the king, the lords ſpiritual and temporal, and

the commons, and is at once the ſeat of the legiſlative authority, and the highſt court of juſtice in Great-Britain. In the houſe of lords, criminal caſes are tried on the impeachment of the commons; and this houſe has an original jurifdiction for the trial of peers upon indictments found by a grand jury; the lords likewiſe try ſuch caſes as come thither on appeals from the court of chancery, and all their decrees are as judgments. The houſe of commons examine the right of elections; regulate diſputes concerning them; may expel their own members, and commit them to priſon. They are the grand inqueſt of the nation; and preſent public grievances or delinquents to the king and lords, in order to their being puniſhed. In ſhort, they are the representatives of all the commons in the kingdom; and in them their conſtituents have placed the highſt confidence, by inveſting them with the power of making laws, and entrufing them with all their liberties and privileges.

Originally, new parliaments were called every year; but by degrees their term grew longer. In the reign of king Charles II. they were held a long time, with great interruptions between: but both methods were found of ſuch ill confequence, that, in the beginning of the reign of king William III. an act was paſſed, by which the term of all parliaments was reſtrained to three ſeſſions, or three years; this was hence called the triennial act: but ſince that time, from other views, the period of parliaments has been lengthened to ſeven years. A parliament is called by the king's writ or letter directed to each lord, commanding him to appear; and by other writs, directed to the ſheriffs of each county, to ſummon the people to elect two knights for each county, and one or two burgeſſes for each borough. The number of the members in the houſe of lords is uncertain, as increaſing at the king's pleaſure. The members of the houſe of commons, when full, are five hundred and fifty-three; *viz.* ninety-two knights of the ſhires; fifty-two deputies for twenty-five cities, London having four; fixteen for the eight cinque-ports; two for each univerſity; three hundred and thirty-two for an hundred and eighty boroughs; twelve for the boroughs in Wales, and forty-five members for Scotland. If three hundred of theſe members are met, it is reckoned a full houſe; and forty may compoſe a houſe for the diſpatch of buſineſs.

Upon the holding of a parliament, the king, the firſt day, ſits in the upper-houſe, under a canopy, with the crown on his head, and dreſſed in his royal robes; and there, by himſelf, or the lord chancellor, declares the reaſons of their meeting, in the preſence of both the lords and commons; and then the commons are required to chuſe a ſpeaker, who is preſented to the king, and being approved by his majeſty, the buſineſs of the parliament goes on.

The lords and commons fit each in a diſtinct apartment; in the houſe of lords, the princes of the blood fit by themſelves on the ſides of the throne; at the wall, on the king's right hand, the two archbiſhops fit by themſelves on a form. Below them, the biſhops of London, Durham, and Wincheſter, and all the other biſhops, fit according to the priority of their conſecration. On the king's left hand the lord-treaſurer, lord preſident, and lord privy-ſeal, fit upon forms above all dukes, except the royal blood; then the dukes, marquifſes, and earls, according,

cording to their creation. Across the room are wool-facks, continued from an ancient custom; and the chancellor, or keeper, being of course the speaker of the house of lords, sits on the first wool-fack before the throne, with the great seal or mace lying by him; below these are forms for the viscounts and barons. On the other wool-facks are seated the judges, masters in chancery, and king's council; who are only to give their advice in points of law: but they all stand up till the king gives them leave to sit. The commons sit promiscuously; only the speaker has a chair at the upper end of the house, and the clerk and his assistant sit at a table near him. Before any business is done, all the members of the house of commons take the oaths of allegiance and supremacy, &c. and subscribe their opinions against transubstantiation, &c. and if any member of that house votes, or sits there during any debate, after the speaker is chosen, without having first taken these oaths, between the hours of nine and four, in a full house, he is adjudged a Popish recusant convict, and incapable of any office, and forfeits five hundred pounds. The same tell the lords too, though they do not take the oaths, are obliged to comply with. When the parliament is thus met, no members are to depart from it without leave. Upon extraordinary occasions, all the members are sometimes summoned; in which case every lord spiritual and temporal, and every knight, citizen, and burges, is to come to parliament, except he can reasonably and honestly excuse himself; or be amerced; that is, respectively, a lord by the lords, and a commoner by the commons.

All members of parliament, in order that they may attend the public service of their country, have the privilege for themselves of being free from arrefts, attachments, imprisonment, &c. for debts, trespasses, &c. but not from arrefts for treason, felony, and breach of the peace.

As to the election of members, it is enacted, That candidates shall not make any presents of money to, or treat the electors, after the test of the writ of the summons, or the issuing out of the writs for elections, or after any seat for a member of parliament is become vacant; in case they do, they are declared incapable of serving as members, by 7 W. III. c. 4. And farther, an oath is to be taken by electors, That they have not either received, or had any money, gift, reward, or any office, place, employment, or even promise of money, gift, &c. to them or their use, to give their votes; and in these cases, if they ask, take, or contract for money or reward, either by gift or other device, to give or refuse their votes for any one; or if persons, by gift, &c. corruptly procure any elector to give his vote; they shall forfeit five hundred pounds, and be totally disabled to vote at any election of members of parliament, as also to hold any office, franchise, &c. Likewise officers who admit persons to vote without their taking the aforementioned oath, in case the same be demanded, incur a forfeiture of one hundred pounds; and an oath is to be administered to all the returning officers, that they have not received any money, gift, or place, for the making of their returns: 2 Geo. II. c. 24. 9 Geo. II. c. 38. A knight of the shire must be worth six hundred pounds a year in land, and all other members three hundred pounds.

Anciently all the people had votes in elections, till it was enacted by Henry VI. that none but freeholders, who had a yearly revenue of forty shillings, should be admitted to vote for knights of the shire.

The manner of debating upon, and passing bills in parliament, is as follows: Any member may move to have a bill brought in, which, upon a question put, being agreed to by the majority, this person, with others, is ordered to prepare and bring in the same. When it is ready, a time is appointed for its being read; and after the clerk's reading it, the speaker reads an abstract of it, and puts the question whether or no it shall have a second reading; and after a second reading, the question is put whether or no it shall be committed, which is either to a committee of the whole house if it be of importance, or to a private committee, any member naming the persons. The committee being appointed, and a chairman chosen, the chairman reads the bill paragraph by paragraph, puts every clause to the question, fills up the blanks, and makes amendments according to the opinion of the majority. The bill thus gone through, the chairman makes his report at the side-bar of the house, reads all the additions and amendments, &c. and moves for leave to bring up the report to the table; which granted, he delivers it to the clerk, who reads the amendments, &c. The speaker then puts the question whether they shall be read a second time; and, if agreed to, he reads them himself. To so many of the amendments as the house acquiesces in, the question is now put, Whether the bill, thus amended, shall be ingrossed and written fair upon parchment, and read a third time? and the bill being ingrossed, the speaker holds it in his hand, and asks if it shall pass. If the majority be for it, the clerk writes on it, *Soit baillie aux seigneurs*, "Let it be delivered to the lords;" or if in the house of lords, *Soit baillie aux communes*, "Let it be delivered to the commons." If a bill be rejected, it cannot be any more proposed during that session. A bill for a general pardon has but one reading.

When a member of the house of commons speaks, he stands up uncovered, and directs his speech to the speaker only. If what he says be answered by another, he is not allowed to reply the same day, unless personal reflections have been cast upon him: but when the commons, in order to have a greater freedom of debate, have resolved themselves into a committee of the whole house, every member may speak to a question as often as he thinks necessary. In the house of lords they vote, beginning at the puiſne, or lowest baron, and so up to the highest, every one answering *Content* or *Not content*. In the house of commons they vote by *yeas* and *nays*; and if it be dubious which are the greater number, the house divides. If the question be about bringing any thing into the house, the *yeas* go out; but if it be about any thing the house already has, the *nays* go out. In all divisions the speaker appoints four tellers, two of each opinion. In a committee of the whole house, they divide by changing sides, the *yeas* taking the right and the *nays* the left of the chair; and then there are but two tellers. If a bill pass one house, and the other demur to it, a conference is demanded in the painted chamber, where certain members are deputed from each house; and here the lords sit covered, and the commons stand bare and debate the case. If they disagree, the affair is null; but if they agree,

gree, this, with the other bells that have passed both houses, is brought down to the king in the house of lords, who comes thither clothed in his royal robes; before him the clerk of the parliament reads the title of each bill, and as he reads, the clerk of the crown pronounces the royal assent or dissent. If it be a public bill, the royal assent is given in these words, *Le roy le veut*, "The king will have it so;" if private, *Soit fait comme il est désiré*, "Let the request be complied with;" if the king refuses the bill, the answer is, *Le roy s'avisera*, "The king will think of it;" and if it be a money-bill, the answer is, *Le roy remercie ses loyaux sujets, accepte leur benevolence, & aussi le veut*; "The king thanks his loyal subjects, accepts their benevolence, and therefore grants his consent."

PARLIAMENTS of France, are sovereign courts, established by the king, finally to determine all disputes between particular persons, and to pronounce on appeals from sentences given by inferior judges. There are ten of these parliaments in France, of which that of Paris is the chief, its privileges and jurisdiction being of the greatest extent. It consists of six chambers, viz. the grand chamber, where causes of audience are pleaded; and five chambers of inquest, where processes are adjudged in writing. This parliament enjoys the privileges of verifying and registering the king's arrests or edicts, without which those edicts are of little or no value.

PARLIAMENT of Sweden, consists of four estates, with the king at their head: These estates are, 1. The nobility and representatives of the gentry; with whom the colonels, lieutenant-colonels, majors, and captains of every regiment, sit and vote. 2. The clergy; one of which body is elected from every rural deanery of ten parishes; who, with the bishops and superintendents, amount to about two hundred. 3. The burghers, elected by the magistrates and council of every corporation as their representatives, of whom there are four for Stockholm, and two for every other town, amounting in the whole to about an hundred and fifty. 4. The peasants, chosen by the peasants out of every district; who chuse one of their own rank, and not a gentleman, to represent them: these amount to about two hundred and fifty.

All these generally meet at Stockholm; and after the state-affairs have been represented to them from the throne, they separate, and sit in four several chambers or houses, in each of which affairs are carried on by majority of votes; and every chamber has a negative in the passing any law.

PARMA, the capital of the duchy of Parma, in Italy, sixty miles north-east of Genoa, is pleasantly situated on a river to which it gives name: E. long. 11°, N. lat. 44° 45'.

PARNASSIA, in botany, a genus of the pentandria tetragynia class. The calix consists of five segments, and the corolla of five petals; it has five cordated nectaria, with round buttons on their points; and the capsule has four valves. There is but one species, viz. the palustris, or grass of Parnassus, a native of Britain.

PARNASSUS, a mountain of Greece, much celebrated by ancient poets, situated near Castro in Livadia.

PARODY, a popular maxim, adage, or proverb.

Parody is also a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule to another; or in turning a serious work into a

burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, and cadences.

PARONOMASIA, in rhetoric, a pun; or a figure whereby words nearly alike in sound, but of very different meanings, are affectedly or designedly used.

PAROS, one of the smallest islands of the Cyclades, famous for its marble, situated in E. long. 25° 30', N. lat. 36° 30'.

PAROTIDES, in anatomy. See **ANATOMY**, p. 270.

PAROXYSM, in medicine, the severe fit of a disease, under which it grows higher, or exasperates, as of the gout, &c.

PARRELS, in a ship, are frames made of trucks, ribs, and ropes, which having both their ends fastened to the yards, are so contrived, as to go round about the masts; that the yards, by their means, may go up and down upon the mast; these also, with the breast-ropes, fasten the yards to the masts.

PARRICIDE. See **LAW**, Tit. xxxiii. 19.

PARROT, in ornithology. See **PSITTACUS**.

PARSLEY, in botany. See **APIUM**.

PARSNAP, in botany. See **PASTINACA**.

PARSON, the rector or incumbent of a parish-church.

PARSONAGE, a rectory or parish-church, endowed with a house, glebe, lands, tithes, &c. for the maintenance of a minister, with cure of souls within such parish.

PARTS of speech, in grammar, are all the sorts of words which enter the composition of discourse. See **GRAMMAR**.

PARTERRE, in gardening, a level division of ground, which, for the most part, faces the south, and best front of an house; and is generally furnished with greens, flowers, &c.

PARTHENIUM, in botany, a genus of the monœcia pentandria class. The common calix of the male consists of five leaves; and the corolla of the dish are monopetalous. The corollæ of the radius in the female are five; two of each side are males, and the intermediate one female, above a naked seed. There are two species, none of them natives of Britain.

PARTHIA, a country of Asia, formerly so called, situated almost in the middle of the modern Persia.

PARTI, PARTIE, PARTY, or PARTED, in heraldry, is applied to a shield or escutcheon, denoting it divided or marked out into partitions.

Parti per pale is when the shield is divided perpendicularly into two halves, by a cut in the middle from top to bottom. See **PLATE CXXXIV. fig. 11.**

Parti per fess is when the cut is across the middle, from side to side.

Parti per bend dexter, is when the cut comes from the upper corner of the shield, on the right hand, and descends athwart to the opposite lower corner.

Parti per bend sinister, is when the cut, coming from the upper left corner, descends across to the opposite lower one.

From these four partitions have proceeded an infinite number of others, of various and extravagant forms.

PARTICIPLE, in grammar, an adjective formed of a verb, so called because it participates partly of the properties of a noun, and partly of those of a verb. See **GRAMMAR**.

PARTICLE, in physiology, the minute part of a body,

an assemblage of which constitute all natural bodies.

It is the various arrangement and texture of these particles, with the difference of cohesion, &c. that constitute the various kinds of bodies. The smallest particles cohere with the strongest attraction, and compose bigger particles of weaker cohesion; and many of these cohering compose bigger particles, whose vigour is still weaker; and hereupon the operations in chemistry, and the colours of natural bodies, depend, and which, by cohering, compose bodies of sensible bulk. The cohesion of the particles of matter, the Epicureans imagined, was effected by means of hooked atoms; the Aristotelians, by rest; but Sir Isaac Newton shews, that it is done by means of a certain power, whereby the particles mutually attract and tend towards each other. By this attraction of the particles, he shews, that most of the phenomena of the lesser bodies are effected, as those of the heavenly bodies are, by the attraction of gravity.

PARTICLE, in grammar, a denomination for all those small words that tie or untie others together, or that express the modes or manners of words. See **GRAMMAR**.

PARTNER, and **PARTNERSHIP**. See **ARITHMETIC**, p. 386.

PARTURIDGE, in ornithology. See **TETRAO**.

PARTURITION. See **DELIVERY**.

PARULIDES, in surgery, tumours and inflammations of the gums, commonly called gum-boils.

They are to be treated with discutients, like other inflammatory tumours.

PARUS, in ornithology. See **CERTHIA**.

PASCHAL, something belonging to the passover or easter. See **PASSOVER**, and **EASTER**.

PAISLEY, a town of Scotland, in the county of Renfrew, six miles west of Glasgow.

PASQUIN, a mutilated statue at Rome, in a corner of the palace of the Ursini: it takes its name from a cobbler of that city called Pasquin, famous for his sneers and gibes, and who diverted himself with passing his jokes on all the people who went through that street. After his death, as they were digging up the pavement before his shop, they found in the earth the statue of an ancient gladiator, well cut, but maimed, and half spoiled; this they set up in the place where it was found, and by common consent named it Pasquin. Since that time, all satires are attributed to that figure; and are either put into its mouth, or passed upon it, as if they were wrote by Pasquin redivivus; and these are addressed by Pasquin to Marforio, another statue at Rome. When Marforio is attacked, Pasquin comes to his assistance; and when Pasquin is attacked, Marforio assists him in his turn.

PASQUINADE, 'a satirical libel fastened to the statue of Pasquin: these are commonly short, merry, and pointed; and from hence the term has been applied to all other lampoons of the same cast.

PASSADE, in the menage, is a turn or course of a horse backwards or forwards, on the same spot of ground.

Birds of PASSAGE, a name given to those birds which at certain stated seasons of the year remove from certain countries, and at other stated times return to them again, as our quails, woodcocks, storks, nightingales, swallows, and many other species. Among the birds of passage, the fieldfare, the redwing, the woodcock, and the snipe, come to us in the autumn, at the time when the

summer-birds are leaving us, and go from us again in spring, at the time when these return; and of these the two last often continue with us through the summer, and breed; so that the two first seem the only kinds that certainly leave us at the approach of spring, retiring to the northern parts of the continent, where they live during the summer, and breed; and at the return of winter, are driven southerly from those frigid climes, in search of food, which there the ice and snow must deprive them of.

PASSANT, in heraldry, a term applied to a lion, or other animal, in a shield, appearing to walk leisurely: for most beasts, except lions, the term trippant is frequently used instead of passant.

PASSAO, or **CAPE PASSAO**, a promontory of Peru, just under the equator: W. long 81°.

PASSAU, the capital of the bishopric of the same name, in the circle of Bavaria, situated on the confluence of the rivers Danube, Inn, and Ilts: E. long. 15° 30', N. lat. 48° 30'.

PASSERES is the name of a class of birds. See **NATURAL HISTORY**.

PASSERINA, in botany, a genus of the octandria monogynia class. It has no calix; the corolla consists of four segments, and the stamina lie upon the tube. There are eight species, none of them natives of Britain.

PASSIFLORA, in botany, a genus of the gynandria pentagynia class. It has three styli; the calix consists of five leaves, and the corolla of five petals; and the nectarium is a corona; and the berry is supported on a pedicle. There are 26 species, none of them natives of Britain, but are cultivated in gardens for the beauty of their flowers.

PASSIONS, in moral philosophy, are certain motions of the soul, which make it pursue what appears to be good, and avoid whatever threatens evil.

By reflecting, says Mr Locke, on the various modifications or tempers of the mind, and the internal sensations which pleasure and pain, good and evil, produce in us, we may thence form to ourselves the ideas of our passions. Thus, by reflecting upon the thought we have of the delight which any thing is apt to produce in us, we form an idea which we call love. Desire is that uneasiness which a man finds in himself upon the absence of any thing, the present enjoyment of which causes delight. Joy is a delight of the mind, arising from the present, or assured approaching, possession of some good. Sorrow is an uneasiness of the mind, upon the thought of a good lost, or the sense of a present evil. Hope is a pleasure in the mind, upon the thought of a probable future enjoyment of a thing which is apt to delight. Fear is an uneasiness of the mind, upon the thought of a future evil likely to befall us. Anger is a discomposure of the mind, upon the receipt of injury, with a present purpose of revenge. Despair is the thought of the unattainableness of any good. Envy is an uneasiness of mind, caused by the consideration of a good we desire, obtained by one we think should not have had it before us.

On the just regulation and subordination of the passions, depends, in a great measure, the happiness of mankind. See **MORAL PHILOSOPHY**.

PASSIONS, in medicine, make one of the non-naturals, and produce very sensible effects. Joy, anger, and fear,

are the principal. In the two first, the spirits are hurried with too great vivacity; whereas, in fear or dread, they are it were curbed and concentrated: whence we may conclude, that they have a very bad effect upon health; and therefore it will be best to keep them within bounds as much as possible, and to preserve an inward serenity, calmness, and tranquillity.

PASSIONS, in painting, are the external expressions of the different dispositions and affections of the mind: but particularly their different effects upon the several features of the face: for though the arms, and indeed every part of the body, serve likewise, by their quick, languid, and variously diversified motions, to express the passions of the soul; yet, in painting, this difference is most conspicuous in the face.

In sorrow, joy, love, shame, and compassion, the eyes swell all of a sudden, are covered with a superabundant moisture, and drop tears; and in grief especially, the corners of the mouth hang down, the eye-lids are half shut, and the pupil of the eye is elevated and half covered; and all the other muscles of the face are relaxed, so that the visage appears longer than ordinary.

In fear, terror, fright, and horror, the eye-brows are greatly elevated; the eye lids are expanded as wide as possible, so as to discover the white of the eye; and the pupil is depressed, and half covered by the lower eye-lid; the hair stands an end; the mouth is at the same time wide open; and the lips so far drawn back, that the teeth, both of the upper and under jaw appear.

Contempt is expressed by raising one side of the upper lip, so as to discover the teeth, whilst the other side has a movement like that in laughter; the eye, on that side where the teeth appear, is half shut, whilst the other remains open; however, both the pupils are depressed.

In jealousy, envy, hatred, and malice, the eye brows are knit; and, in laughter, all the parts agree, tending as it were towards the centre of the face.

PASSION, or *cross* of the **PASSION**, in heraldry, is so called, because resembling the shape of that on which our Saviour is thought to have suffered; that is, not crossed in the middle, but a little below the top, with arms short in proportion to the length of the shaft. See plate CXXXIV. fig. 12.

PASSION-FLOWER, in botany. See **PASSIFLORA**.

PASSION-WEEK, the week immediately preceding the festival of Easter: so called, because in that week our Saviour's passion and death happened.

The Thursday of this week is called Maunday Thursday; the Friday, Good Friday; and the Saturday, the great Sabbath.

PASSIVE, in general, denotes something that suffers the action of another called an agent or active power.

In grammar, the verb or word that expresses this passion, is termed a passive verb: which, in the learned languages, has a peculiar termination, as *amor, docetor*, &c. in Latin.

PASSIVE TITLE, in Scots law. See **LAW**, Tit. xxvii. 30.

PASSOVER, a solemn festival of the Jews, celebrated on the fourteenth day of the month next after the vernal equinox, and instituted in commemoration of their coming out of Egypt; because on the night before their departure the destroying angel, who put to death the first-born of the Egyptians, passed over the houses of the Hebrews, which were sprinkled with the blood of a lamb. The whole

transaction is related in the twelfth chapter of **Exodus**. **PASS PAROLE**, a command given at the head of an army, and thence communicated to the rear by passing it from mouth to mouth.

PASS-PORTR, or **PASS**, a licence or writing obtained from a prince or governor, granting liberty and safe conduct to pass through his territories without molestation.

PASTEBOARD, a kind of thick paper formed of several sheets of paper pasted together.

The chief use of pasteboard is in binding books, making letter-cases, &c.

PASTER of a horse, in the manege, is the distance between the joint next the foot, and the coronet of the hoof. This part should be short, especially in middle-sized horses, because long pasterns are weak, and cannot so well endure travelling.

PASTER-JOINT, the joint next a horse's foot

PASTIL, or **PASTEL**, among painters, a kind of paste made of different colours, ground up with gum-water, in order to make crayons

PASTIL, in pharmacy, is a dry composition of sweet-smelling resins, aromatic woods, &c. sometimes burnt to clear and scent the air of a chamber.

PASTINACA, in botany, a genus of the pentandria digynia class. The fruit is elliptical, and compressed. There are two species, none of them natives of Britain; but the fativa, or parsnep, is cultivated in gardens for the sake of its root, which we use as food.

PASTORAL, in general, something that relates to shepherds; hence we say, pastoral life, manners, poetry, &c.

The original of poetry is ascribed to that age which succeeded the creation of the world: and as the keeping of flocks seems to have been the first employment of mankind, the most ancient sort of poetry was, probably, pastoral. It is natural to imagine, that the leisure of those ancient shepherds admitting and inviting some diversion, none was so proper to that solitary and sedentary life as singing; and that in their songs they took occasion to celebrate their own felicity. From hence a poem was invented, and afterwards improved to a perfect image of that happy time; which, by giving us an esteem for the virtues of a former age, might recommend them to the present. And since the life of shepherds was attended with more tranquillity than any other rural employment, the poets chose to introduce their persons, from whom it received the name of Pastoral.

A pastoral is an imitation of the action of a shepherd, or one considered under that character. The form of this imitation is dramatic, or narrative, or mixed with both; the fable simple; the manners not too polite, nor too rustic; the thoughts are plain, yet admit a little quickness and passion, but that short and flowing; the expression humble, yet as pure as the language will afford; neat, but not florid; easy, and yet lively. In short, the fable, manners, thoughts, and expressions, are full of the greatest simplicity in nature.

The complete character of this poem consists in simplicity, brevity, and delicacy; the two first of which render an eclogue natural, and the last delightful.

PASTRY, that branch of cookery, which is chiefly taken up in making pies, pasties, cakes, &c.

PASTURE, or **PASTURE-LAND**, that reserved for feeding cattle.

Pasture.

Pasture land is of such advantage to husbandry, that many prefer it even to corn-land, because of the small hazard and labour that attends it, and as it lays the foundation for most of the profit that is expected from the arable land, because of the manure the cattle afford which are fed upon it. Where dung is not to be bought, as is often the case in places distant from large towns, the farmer is forced to proportion his arable to his pasture-land, in such manner, that the cattle fed on the latter may be sufficient for a supply of dung, so necessary for producing the fruits of the former.

PATAGONIA, the most southern part of South America, extending from the mouth of Rio di la Plata, in 36° of S. lat. to Cape-Horn, in $55^{\circ} 30'$.

PATAGONULA, or **PATAGONICA**, in botany, a genus of the pentandria monogynia class. The corolla is rotated; and the stylus is dichotomous. There is but one species, a native of America.

PATAN, the capital of a province in the East Indies, situated two hundred miles north of Hugly in Bengal: E. long. 89° , N. lat. $27^{\circ} 30'$.

PATAVINITY, among critics, denotes a peculiarity of Livy's diction, derived from Patavium, or Padua, the place of his nativity; but wherein this patavinity consists, they are by no means agreed.

PATCHUCA, or **PATIOQUE**, a city of Mexico, W. long. 103° , N. lat. 21° ; subject to Spain.

PATE, in fortification, a kind of platform, resembling what is called an horse-shoe.

PATE'E, or **PATTE'E**, in heraldry, a cross, small in the centre, and widening to the extremes, which are very broad. See Plate CXXXIV. fig. 13. which is a cross patée, argent, upon a field sable.

PATELLA, in anatomy. See **ANATOMY**, p. 185.

PATELLA, the **LIMPET**, is a genus of insects belonging to the order of vermes testacea. It is an animal of the snail kind; the shell consists of one conical valve, without any spiral. There are 36 species, principally distinguished by peculiarities in their shells.

PATENT, in general, denotes something that stands open or expanded; thus a leaf is said to be patent when it stands almost at right angles with the stalk.

PATENT, or **LETTERS-PATENT**. See **LETTER**.

PATER PATRATUS, in Roman antiquity, the principal person among the *faciales* or college of heralds.

PATER NOSTER, the Lord's-prayer, so called from the two first words thereof in Latin.

PATH, in general, denotes the course or tract marked out or run over by a body in motion. For the path of the moon, &c. see **ASTRONOMY**, p. 465.

PATHETIC, whatever relates to the passions, or that is proper to excite or awake them.

PATHOGNOMONIC, among physicians, an appellation for a symptom, or concurrence of symptoms, that are inseparable from a distemper, and are found in that only, and in no other.

PATHOLOGY, that part of medicine, which explains the nature of diseases, their causes and symptoms.

PATHOS, a Greek term, literally signifying passion, is sometimes used for the energy of a discourse, or its power to move the passions.

PATMOS, one of the least of the islands of the Archipelago, subject to the Turks: E. long. 27° , and N. lat. 37° .

PATNA, a city of the hither India, the capital of the territory of the same name, in the province of Bengal: E. long. 85° , and N. lat. 26° .

PATANCE, in heraldry, is a cross, flory at the ends; from which it differs only in this, that the ends, instead of turning down like a fleur-de-lis, are extended somewhat in the pattee-form. See **FLOREY**.

PATOWMAC, a great river of Virginia, which arises in the Apalachian mountains, and after separating Virginia from Maryland falls into the bay of Chesapeake.

PATRAS, a city and port-town of European Turkey, in the province of the Morea: E. long. $21^{\circ} 30'$, and N. lat. $38^{\circ} 20'$.

PATRES CONSCRIPTI. See **CONSCRIPT** and **SENATOR**.

PATRIARCHS, among Christians, are ecclesiastical dignitaries, or bishops, so called from their paternal authority in the church. The power of patriarchs was not the same in all, but differed according to the different customs of countries, or the pleasures of kings and councils: thus the patriarch of Constantinople grew to be a patriarch over the patriarchs of Ephesus and Caesarea, and was called the oecumenical and universal patriarch; and the patriarch of Alexandria had more prerogatives, which no other patriarch besides himself enjoyed, such as the right of consecrating and approving every single bishop under his jurisdiction.

PATRIARCHAL cross, in heraldry, is that where the shaft is twice crossed; the lower arms being longer than the upper ones. Plate CXXXIV. fig. 14. is a patriarchal cross, gules, on a field argent.

PATRICIAN, among the ancient Romans, a title given to the descendants of the hundred, or, according to others, of the two hundred first senators chosen by Romulus, and by him called *Patres*, *Fathers*.

PATRIMONY, a right or estate inherited by a person from his ancestors.

PATRINGTON, a market-town of Yorkshire, situated at the mouth of the Humber, fifty miles east of York.

PATRIPASSIANS, in church-history, a Christian sect, which appeared about the latter end of the 11th century; so called from their ascribing the passion to the Father: for they asserted the unity of God in such a manner as to destroy all distinction of persons, and to make the Father and Son precisely the same; in which they were followed by the Sabellians, and others. The author and head of the patripassians was Praxeas, a philosopher of Phrygia in Asia.

PATROL, in war, a round or march made by the guards, or watch, in the night-time, to observe what passes in the streets, and to secure the peace and tranquillity of a city or camp.

PATRON, among the Romans, was an appellation given to a master who had freed his slave. As soon as the relation of master expired, that of patron began: for the Romans, in giving the slaves their freedom, did not despoil themselves of all right and privileges in them; the law still subjected them to considerable services and duties towards their patrons, the neglect of which was very severely punished.

PATRON, in the church of Rome, a saint, whose name a person bears, or under whose protection he is put, and whom he takes particular care to invoke; or a saint, in whose name a church or order is founded.

PATRON, in Scots law. See **LAW**, Tit. v. 5.

PATRONAGE, the right of disposing a church or benefice, and enjoying several other privileges, such as having the honourable rights of the church, being interred in the chancel, &c.

Aims of PATRONAGE, in heraldry, are those on the top of which are some marks of subjection and dependance: thus the city of Paris bears the fleurs-de-lis in chief, to shew her subjection to the king; and the cardinals on the top of their arms, bear those of the pope, who gave them the hat, to shew that they are his creatures.

PATRONYMIC, among grammarians, is applied to such names of men and women as are derived from those of parents or ancestors.

PAVETTA, in botany, a genus of the tetrandria monogynia class. The corolla consists of one funnel shaped petal; the stylus is crooked; and the berry contains one seed. There is but one species, a native of India.

PAVIA, a city of Italy, in the duchy of Milan, capital of the Pavese, the see of a bishop, and university; situated in E. long. 9° 40', and N. lat. 45° 15'.

PAVIA in botany. See **ASCULUS**.

PAULIONISTS, in church-history, Christian heretics of the III^d century, disciples of Paul Samosatensis bishop of Antioch, who denied Christ's divinity, maintaining that when we call him the Son of God, we do not thereby mean that he is really and truly God; but only that he was so perfect a man, and so superior in virtue to all others, that he had this name given him by way of eminence.

PAULICIANS, Christian heretics of the VIIth century, disciples of one Constantine, a native of Armenia, and a favourer of the errors of Manes; who, as the name Manichees was become odious to all nations, gave those of his sect the title of Paulicians, on pretence that they followed only the doctrine of St Paul.

PAULINIA, in botany, a genus of the octandria trigynia class. The calix consists of four leaves, the corolla of four petals, and the nectarium of four unequal leaves; it has three compressed, membranaceous capsules. There are seven species, none of them natives of Britain.

PAVO, in ornithology, a genus belonging to the order of gallinæ. The head is covered with feathers which bend backwards; and the feathers of the tail are very long, and beautifully variegated with eyes of different colours. There are three species, viz. 1. The cristatus, or common peacock of English authors, has a compressed crest, and solitary spurs, and is a native of Ceylon. 2. The bicalcaratus, has a small crest, and double spurs: It is a native of China. 3. The muticus, has a sharp pointed crest, and no spurs, and the orbits of the eyes are red. It is found in Japan.

Pavo, in astronomy. See **ASTRONOMY**, p. 487.

PAURÆDRASTYLÆ, in natural history, the name of a genus of perfect crystals, with double pyramids, and no intermediate column, composed of twelve planes, or two hexangular pyramids, joined base to base.

PAUSANIA, in Grecian antiquity, a festival, in which were solemn games, wherein nobody contended but free-born Spartans; in honour of Pausanias, the Spartan general, under whose conduct the Greeks overcame Marodonius, in the famous battle at Platææ.

PAUSE a stop or cessation of speaking, singing, playing,

or the like. The use of pointing in grammar, is to make proper pauses, in certain places. There is a pause in the middle of each verse; in an hemistich it is called a rest or repose.

PAW, in the menage. A horse is said to paw the ground, when his leg, being either tired or painful, he does not rest it upon the ground, and fears to hurt himself as he walks.

PEA, in botany. See **PISUM**.

PEACH, in botany. See **AMYGDALUS**.

PEACOCK, in ornithology. See **PAVO**.

PEAK, a rocky mountainous country in the west of Derbyshire, remarkable for its mines of lead and iron, &c.

PEAN, in heraldry, is when the field of a coat of arms is fable, and the powderings or.

PEAR, in botany. See **PYRUS**.

PEARCH, in ichthyology. See **PERCA**.

PEARCH-GLUE, the name of a kind of glue of remarkable strength and purity, made from the skins of peaches.

PEARL, in natural history, a hard, white, shining body, usually roundish, found in a testaceous fish resembling an oyster.

Pearls though esteemed of the number of gems by our jewellers, and highly valued, not only at this time, but in all ages, proceed only from a disemper in the creature that produces them, analogous to the bezoars, and other stony concretions in several animals of other kinds.

The fish in which these are usually produced is the East-Indian pearl-oyster, as it is commonly called. Besides this shell, there are many others that are found to produce pearls; as the common oyster, the muscle, and several others; the pearls of which are often very good; but those of the true Indian berberi, or pearl-oyster, are in general superior to all. The small or seed-pearls, also called ounce-pearls, from their being sold by the ounce, and not by tale, are vastly the most numerous and common; but as in diamonds, among the multitudes of small ones, there are smaller numbers of larger found, so in pearls there are larger and larger kinds; but as they increase in size, they are proportionably less frequent, and this is one reason of their great price. We have Scotch pearls frequently as big as a little tare, some as big as a large pea, and some few of the size of a horse-bean; but these are usually of a bad shape, and of little value in proportion to their weight. Philip II. of Spain, had a pearl perfect in its shape and colour, and of the size of a pigeon's egg. The finest, and what is called the true shape of the pearl, is a perfect round; but if pearls of a considerable size are of the shape of a pear, as is not unfrequently the case, they are not less valued, as they serve for ear-rings and other ornaments. Their colour ought to be a pure white, and that not a dead and lifeless, but a clear and brilliant one; they must be perfectly free from any foulness, spot or stain; and their surfaces must be naturally smooth and glossy; for they bring their natural polish with them, which art is not able to improve.

All pearls are formed of the matter of the shell, and consist of a number of coats spread with perfect regularity one over another, in the manner of the several coats of an onion, or like the several strata of the stones found in the bladders or stomachs of animals, only much thinner.

Manner of fishing for PEARLS in the East Indies. There are two seasons for pearl-fishing: the first is in March and

April, and the last in August and September; and the more rain there falls in the year, the more plentiful are these fisheries. At the beginning of the season there are sometimes two hundred and fifty barks on the banks; the larger barks having two divers, and the smaller one. As soon as the barks arrive at the place where the fish lie, and have cast anchor, each diver binds a stone six inches thick, and a foot long, under his body; which serves him as ballast, prevents his being driven away by the motion of the water, and enables him to walk more steadily under the waves. They also tie another very heavy stone to one foot, by which they are very speedily sent to the bottom of the sea: and as the oysters are usually firmly fastened to the rocks, they arm their hands with leather mittens to prevent their being wounded in pulling them violently off; but this task some perform with an iron-rake. In the last place, each diver carries down with him a large net in the manner of a sack, tied to his neck by a long cord, the other end of which is fastened to the side of the bark. This net is to hold the oysters gathered from the rock, and the cord is to pull up the diver when his bag is full or he wants air.

In this equipage he sometimes precipitates himself sixty feet under water; and as he has no time to lose, he no sooner arrives at the bottom, than he begins to run from side to side tearing up all the oysters he meets with, and cramming them into his budget.

At whatever depth the divers are, the light is so great, that they easily see whatever passes in the sea: and to their great consternation sometimes perceive monstrous fishes, from which all their address in mudding the water, &c. will not always save them, but they unhappily become their prey: and of all the dangers of the fishery, this is one of the greatest and most usual. The best divers will keep under water near half an hour, and the rest do not stay less than a quarter. During this time they hold their breath without the use of oils, or any other liquors; only acquiring the habit by long practice. When they find themselves straightened, they pull the rope to which the bag is fastened, and hold fast by it with both hands; when those in the bark, taking the signal, heave them up into the air, and unload them of their fish, which is sometimes five hundred oysters, and sometimes not above fifty. Some of the divers need a moment's respite to recover breath: others jump in again instantly, continuing this violent exercise without intermission for several hours.

On the shore they unload their barks, and lay their oysters in an infinite number of little pits dug in the sand four or five feet square; raising heaps of sand over them to the height of a man; and in this condition they are left, till the rain, wind, and sun have obliged them to open, which soon kills them: upon this the flesh rots and dries, and the pearls, thus disengaged, fall into the pit, on their taking out the shells. After clearing the pits of the grosser filth, they sift the sand several times in order to find the pearl: but whatever care they take, they always lose a great many. After cleaning and drying the pearls, they are passed through a kind of sieve, according to their sizes; the smallest are then sold as seed-pearls, and the rest put up to auction, and sold to the highest bidder.

Artificial PEARLS, are made by reducing seed-pearls to a

paste, by means of a chemical preparation called mercurial water, making the beads in silver-moulds, boring them with a hog's bristle, and drying them in a closed glass in the sun.

Beads, in imitation of pearls, are also made of wax, and covered with the scales of several kinds of fishes.

Mother of PEARL, is the shell, not of the pearl-oyster, but of another sea-fish of the oyster-kind. This shell on the inside is extremely smooth, and of the whiteness and water of pearl itself; and it has the same lustre on the outside, after the first lamina or scales have been cleared off with aquafortis and the lapidaries mill. Mother of pearl is used in inlaid works, and in several toys, as snuff-boxes, &c.

PEARL-ISLANDS, several small islands situated in the bay of Panama: W. long. 81° and between 7° and 9° of north lat.

PEAT, a kind of turf used for fuel in several countries.

PEBBLES, the name of a genus of fossils, distinguished from the flints and homochroa by their having a variety of colours. These are defined to be stones, composed of a crystalline matter, debased by earths of various kinds in the same species, and then subject to veins, clouds, and other variegations; usually formed by incrustations round a central nucleus, but sometimes the effect of a simple concretion, and veined like the agates, by the disposition the motion of the fluid they were formed in gave them differently coloured substances.

PECCANT, in medicine, a term used for those humours of the body which offend either by their quantity or quality.

PECK, a measure of capacity, four of which make a bushel. *PECORA*, in natural history, the name of a class of quadrupeds. See *NATURAL HISTORY*.

PECTORAL, an epithet for medicines good for disorders of the breast and lungs.

PECTORALIS, in anatomy. See *ANATOMY*, p. 194, 195.

PECTORIS os, in anatomy. See *ANATOMY*, p. 175.

PECULIUM, the stock or estate which a person in the power of another, as a slave, may acquire by his industry.

PEDAGOGUE, a tutor or master, to whom is committed the discipline and direction of a scholar.

PEDANT, is used for a rough unpolished man of letters, who makes an impertinent use of the sciences, and abounds in unseasonable criticisms and observations.

PEDARIAN, in Roman antiquity, those senators who signified their votes by their feet, not their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the house.

PEDESTAL, in architecture. See *ARCHITECTURE*, p. 356.

PEDICLE, among botanists, that part of a stalk which immediately sustains the leaf of a flower or a fruit, and is commonly called a foot-stalk.

PEDICULARIS, in botany, a genus of the didynamia angiospermia class. The calix consists of five segments; the capsule is sharp-pointed, oblique, and has two cells; and the seeds are covered with a tunic. There are 14 species, two of which are natives of Britain, viz. the sylvestrica, or common louse-wort; and the palustris, or marsh louse-wort.

This plant is of a cooling and drying nature, whence

it is recommended in fistulas and other sinous ulcers.
PEDICULUS, *Louse*, in zoology, a genus of insects belonging to the order of aptera. It has six feet, two eyes, and a sort of sting in the mouth; the feelers are as long as the thorax; and the belly is depressed, and sub-lobated. There are 40 species, denominated from the different creatures they inhabit. The best antidote against this kind of vermin, is cleanliness.

PEDILUVIUM, a bathing of the feet. This bath may be prepared of the same ingredients with other baths. It may either consist of light pure water alone; or, to correct the qualities of heavy and hard water, a lixivium or bran of wheat or chamomile-flowers may be added.

PEDIMENT, in architecture. See **ARCHITECTURE**, p. 356.

PEDIR, a town in the island of Sumatra, in the East Indies, situated in E. long 94° lat. 5°.

PEDUNCLE, among botanists. See **PEDICLE**.

PEDUNCULI CEREBELLI, in anatomy. See **ANATOMY**, p. 287.

PEEBLES, a town of Scotland, capital of the shire of Tweedale, situated on the river Tweed, twenty-two miles south of Edinburgh.

PEEK, in the sea-language, is a word used in various senses. Thus the anchor is said to be a peek, when the ship being about to weigh comes over her anchor in such a manner that the cable hangs perpendicularly betwixt the hauls and the anchor. To heave a peek is to bring the peek so as that the anchor may hang a-peek.

PEER, in general, signifies an equal, or one of the same rank and station.

The term peer is now applied to those who are impeached in an inquest upon a person for convicting or acquitting him of any offence laid to his charge; and the reason why the jury is so called, is, because by the common law, and the custom of this kingdom, every person is to be tried by his peers or equals, a lord by the lords, and a commoner by commoners.

PEER of the realm, a noble lord who has a seat and vote in the house of lords, which is also called the house of peers. These lords are called peers, because, though there is a distinction of degrees in our nobility, yet in public actions they are equal, as in their votes in parliament, and in trying any nobleman or other person impeached by the commons, &c. See **PARLIAMENT**.

PEERS of France, the twelve great lords of that kingdom, of which six are dukes, and six counts; and of these, six are ecclesiastics, and six laymen: thus, the archbishop of Rheims, and the bishop of Laon and Langres are dukes and peers; and the bishops of Chalons on the Marne, Noyons, and Beauvais, are counts and peers. The dukes of Burgundy, Normandy, and Aquitaine, are lay peers and dukes; and the counts of Flanders, Champagne, and Toulouse, lay peers and counts. These peers still assist at the coronation of kings; either in person or by their representatives, where each performs the functions attached to his respective dignity: but as the six lay peerages are all at present united to the crown except that of the count of Flanders, six lords of the first quality are chosen to represent them; but the ecclesiastical peers usually assist in person. At present the title of peer is bestowed on every lord whose estate is erected into a peerage, the num-

ber of which is uncertain, and it depends entirely on the king.

PEERESS, a woman who is noble by descent, creation, or marriage.

If a peeress, by descent or creation, marries a person under the degree of nobility, she still continues noble; but if she obtains that dignity only by marriage, she loses it on her afterwards marrying a commoner; yet, by the courtesy of England, she always retains the title of her nobility.

PEEVIT, in ornithology. See **LARUS**.

PEGANUM, in botany, a genus of the dodecandria monogynia class. The corolla consists of five petals, and the calyx of five leaves; the capsule has three cells, and three valves, containing many seeds. There are two species; none of them natives of Britain.

PEGASUS, in astronomy. See **ASTRONOMY**, p. 487.

PEGU, the capital of the kingdom of Pegu, and situated upon a river of the same name, in 97° E. long. and N. lat. 17° 30'.

PEKIN, the metropolis of the empire of China, is situated in E. long. 111°, and N. lat. 40°.

It is about twenty miles in circumference, and is said to contain 2,000,000 of people.

PELAGIANS, a Christian sect who appeared about the latter end of the fourth, or the beginning of the fifth century.

Pelagius, the author of this sect, was born in Wales, and his name was Morgan, which in the Welsh language signifies sea-born; from whence he had his Latin name Pelagius. Some of our ancient historians pretend that he was abbot of Bangor: but this is impossible, because the British monasteries were of a later date. St Austin gives him the character of a very pious man, and a Christian of no vulgar rank: according to the same father, he travelled to Rome, where he associated himself with persons of the greatest learning and figure, and wrote his commentaries on St Paul's Epistles, and his letters to Melania and Demetrias; but being charged with heresy, he left Rome, and went into Africa, and from thence to Jerusalem, where he settled. He died somewhere in the east; but where, is uncertain. He was charged with maintaining the following doctrines: 1. That Adam was by nature mortal, and, whether he had sinned or not, would certainly have died. 2. That the consequences of Adam's sin were confined to his own person. 3. That newborn infants are in the same condition with Adam before the fall. 4. That the law qualified men for the kingdom of heaven, and was founded upon equal promises with the gospel. 5. That the general resurrection of the dead does not follow in virtue of our Saviour's resurrection. 6. That the grace of God is given according to our merits. 7. That this grace is not granted for the performance of every moral act; the liberty of the will, and information in points of duty being sufficient, &c.

PELICANUS, in ornithology, a genus belonging to the order of anseres. The bill is straight, without teeth, and crooked at the point; the face is naked; and the feet are palmated. There are eight species, principally distinguished by the shape of their tails.

PELICAN, in ornithology. See **PELICANUS**.

PELICAN, in chemistry. See **CHEMISTRY**, p. 109.

PELLETS,

- PELLETS**, in heraldry, those roundles that are black, called also ogrefts and gunstones, and by the French *torceaux de sable*.
- PELLICLE**, among physicians, &c. denotes a thin film, or fragment of a membrane.
- PELVIS**, in anatomy. See *ANATOMY*, p. 173.
- PEMBROKE**, the capital of Pembrokeshire, in south Wales: W. long. 5°, N. lat. 51° 45'. This town sends two members to parliament.
- PENAL action**, in Scots law. See *LAW*, Tit. xxx. 17.
- PENANCE**, a punishment, either voluntary, or imposed by authority, for the faults a person has committed. Penance is one of the seven sacraments of the Romish church. Besides fasting, alms, abstinence, and the like, which are the general conditions of penance; there are others of a more particular kind, as the repeating a certain number of ave-maries, pater-nosters, and credos, wearing a hair-shirt, and giving one's self a certain number of stripes. In Italy and Spain it is usual to see Christians almost naked, loaded with chains and a cross, and lashing themselves at every step.
- PENEA**, in botany, a plant of the tetrandria monogynia class. The calix consists of two leaves; the corolla is bell shaped; the stylus is quadrangular; and the capsule is triangular, with four cells containing eight seeds. There are three species, none of them natives of Britain.
- PENATES**, in Roman antiquity, a kind of tutelal deities, either of countries or particular houses; in which last sense, they differed in nothing from the lares. See *LARES*.
- PENCIL**, an instrument used by painters for laying on their colours. Pencils are of various kinds, and made of various materials; the larger sorts are made of boars bristles, the thick ends of which are bound to a stick, bigger or less according to the uses they are designed for: these, when large, are called brushes. The finer sorts of pencils are made of camels, badgers, and squirrels-hair, and of the down of swans; these are tied at the upper end with a piece of strong thread, and inclosed in the barrel of a quill.
- PENDANT**, an ornament hanging at the ear, frequently consisting of diamonds, pearls, and other precious stones.
- PENDANTS**, in heraldry, parts hanging down from the label, to the number of three, four, five, or six at most, resembling the drops in the Doric frieze. When they are more than three, they must be specified in blazoning.
- PENDANTS** of a ship, are those streamers or long colours which are split and divided into two parts ending in points, and hung at the head of masts, or at the yard-arm ends.
- PENDULOUS**, a term applied to any thing that bends or hangs downwards.
- PENDULUM**, in mechanics, denotes any heavy body, so suspended as that it may vibrate or swing, backwards and forwards, about some fixed point, by the force of gravity. See *MECHANICS*.
- PENETRALE**, in Roman antiquity, properly denoted the chapel consecrated to the penates, or household-gods.
- PENQUIN ISLAND and BAY**, are situated on the coast of Patagonia in South America: W. long. 70°, S. lat. 47°.
- PENGUIN**, in ornithology. See *ALCA*.
- PENICHE**, a port-town of Portugal, in the province of Eitremadura, situated on the Ocean forty miles north of Lisbon: W. long. 9° 6', N. lat. 39° 20'.
- PENICILLUS**, among surgeons, is used for a tent to be put into wounds or ulcers.
- PENINSULA**, in geography, a portion or extent of land, joining to the continent by a narrow neck or isthmus, the rest being encompassed with water.
- PENIS**, in anatomy. See *ANATOMY*, p. 270.
- PENISCOLA**, a port-town of Spain, in the province of Valencia, situated on the Mediterranean, under the meridian of London, and in N. lat. 40° 29'.
- PENNY**, an ancient silver-coin, which, though now little used, was the only one current among our Saxon ancestors.
- PENNY-EARTH**, in agriculture, denotes a hard, loamy, or sandy earth, with a large proportion of sea-shells intermixed with it.
- PENNY-WEIGHT**, a troy-weight, containing twenty-four grains, each of which is equal in weight to a grain of wheat, gathered out of the middle of the ear, and well dried.
- PENRISE**, a port-town of Wales, in the county of Glamorgan, situated on Bristol channel, seventeen miles south of Caermarthen.
- PENRYN**, a borough-town of Cornwall, near a bay of the English channel: W. long. 5° 35', N. lat. 50° 20'. It sends two members to parliament.
- PENSANCE**, a market-town of Cornwall, eight miles east of the Land's end.
- PENSILVANIA**, one of the English plantations in America, two hundred miles in length, and almost as much in breadth: situated between 74 and 78° of west longitude, and between 39 and 42° of north latitude: a fine fruitful country, bounded by the five nations of the Iroquois on the north, by New-Jersey and New-York on the east, and by Maryland on the south and west. It is a proprietary government, the heirs of Mr. Penn, a quaker, who settled this country, appointing the governor.
- PENSION**, a sum of money paid annually for services or considerations already past. The yearly payment of each member to the houses of the inns of courts, are likewise termed pensions; and the yearly assembly of the members of the society of Gray's Inn, to consult on the affairs of the house, is also called a pension.
- PENSIONER**, in general, denotes a person who receives a pension, yearly salary, or allowance. Hence,
- The band of gentleman-pensioners, the noblest sort of guard to the king's person, consists of forty gentlemen, who receive a yearly pension of one hundred pounds. This honourable band was first instituted by king Henry VIII. and their office is to attend the king's person, with their battle-axes, to and from his chapel-royal, and to receive him in the presence chamber, or coming out of his privy-lodgings; they are also told to attend at all great solemnities, as coronations, St. George's feast, public audiences of ambassadors, at the sovereign's going to parliament, &c.
- They are each obliged to keep three double horses and a servant, and so are properly a troop of horse. They wait half at a time, quarterly; but on Christmas-day, Easter-day, Whitunday, &c. and on extraordinary occasions, they are all obliged to give their attendance.
- PENTACROSTIC**, in poetry, a set of verses so disposed as that there are always five acrostics of the same name, in five divisions of each verse.
- PENTAEDROSTYLA**, in natural history, the name of a genus of spars. See *SPAR*.

The bodies of this genus are spars, in form of pentagonal columns, terminated by pentangular pyramids at one end, and irregularly affixed at the other to some solid body.

PENTAGON, in geometry, a figure of five sides and five angles. See **GEOMETRY**.

PENTAGRAPH, an instrument whereby designs of any kind may be copied in what proportion you please, without being skilled in drawing.

PENTAMETER, in ancient poetry, a kind of verse consisting of five feet, or metres; whence the name.

The two first feet may be either dactyls or spondee, at pleasure; the third is always a spondee, and the two last anapests.

PENTANDRIA, in botany. See **BOTANY**, p. 635.

PENTAPETALOUS, an appellation given to flowers that consist of five petals or leaves.

PENTAPETES, in botany, a genus of the morcodelphia decandria class. The calix is simple; the capsule has five cells, containing many membranaceous seeds. There are three species, none of them natives of Britain.

PENTASTYLE, in architecture, a building wherein there are five rows of columns.

PENTATEUGH, an appellation given to the first five books of the Old Testament, viz. Genesis, Exodus, Leviticus, Numbers, and Deuteronomy, &c.

PENTATHLON, in antiquity, a general name for the five exercises performed at the Grecian games, viz. wrestling, boxing, leaping, running, and playing at the discus.

PENTECOST, a solemn festival of the Jews, so called because it was celebrated on the fiftieth day after the sixteenth of the month Nisan, which was the second day of the passover. See **PASSOVER**.

The feast of pentecost was instituted in memory of the Law's being given on the fiftieth day after the Israelites came out of Egypt.

PENTHORUM, in botany, a genus of the decandria pentagynia class. The calix consists of five segments; the petals are from five to nine; and the capsule has five cells. There is but one species, viz. the sedoides, a native of Virginia.

PENULTIMA, or **PENULTIMATE SYLLABLE**, in grammar, denotes the last syllable but one of a word, and hence the anti-penultimate syllable is the last but two, or that immediately before the penultima.

PENUMBRA, in astronomy, a partial shade observed between the perfect shadow and the full light in an eclipse.

It arises from the magnitude of the sun's body; for were he only a luminous point, the shadow would be all perfect; but by reason of the diameter of the sun, it happens that a place which is not illuminated by the whole body of the sun does yet receive rays from a part thereof.

PEPLIS, in botany, a genus of the hexandria monogynia class. The perianthium is bell-shaped, with twelve segments; the petals are six, inserted into the calix; and the capsule has two cells. There are two species, none of them natives of Britain.

PEPO, in botany. See **CUCURBITA**.

PEPPER, in botany. See **PIPER**.

PEPPER-MINT. See **MENTHA**.

PERA, one of the suburbs of Constantinople, where ambassadors and Christians usually reside.

PERAMBULATOR, in surveying, an instrument for

measuring distances, called also pedometer, way-wiser, and surveying wheel.

It consists of a wheel AA (Plate CXXXIV. fig. 15. n° 1.) two feet seven inches and a half in diameter; consequently half a pole, or eight feet three inches, in circumference. On one end of the axis is a nut, three quarters of an inch in diameter, and divided into eight teeth; which, upon moving the wheel round, fall into the eight teeth of another nut c (*ibid.* n° 2.) fixed on one end of an iron-rod Q, and thus turn the rod once round in the time the wheel makes one revolution. This rod, lying along a groove in the side of the carriage of the instrument, under the dotted line, has at its other end a square hole, into which is fitted the end b of a small cylinder P. This cylinder is disposed (*ibid.* n° 3.) under the dial-plate of a movement, at the end of the carriage B, in such a manner as to be moveable about its axis: its end a is cut into a perpetual screw, which falling into the thirty-two teeth of a wheel perpendicular thereto, upon driving the instrument forward, that wheel makes a revolution each sixteenth pole. On the axis of this wheel is a pinion with six teeth, which, falling into the teeth of another wheel of sixty teeth, carries it round every hundred and sixtieth pole, or half a mile.

This last wheel, carrying a hand or index round with it over the divisions of a dial-plate, whose outer limb is divided into one hundred and sixty parts, corresponding to the one hundred and sixty poles, points out the number of poles passed over. Again, on the axis of this last wheel is a pinion, containing twenty teeth, which falling into the teeth of a third wheel which hath forty teeth, drives it once round in three hundred and twenty poles, or a mile. On the axis of this wheel is a pinion of twelve teeth, which, falling into the teeth of a fourth wheel having seventy-two teeth, drives it once round in twelve miles.

This fourth wheel, carrying another index over the inner limb of the dial-plate, divided into twelve for miles, and each mile subdivided into halves, quarters, and furlongs, serves to register the revolutions of the other hand, and to keep account of the half miles and miles passed over as far as twelve miles.

The use of this instrument is obvious from its construction. Its proper office is in the surveying of roads and large distances, where a great deal of expedition, and not much accuracy, is required. It is evident, that driving it along, and observing the hands, has the same effect as dragging the chain, and taking account of the chains and links.

Its advantages are its handiness and expedition; its contrivance is such, that it may be fitted to the wheel of a coach, in which state it performs its office, and measures the road without any trouble at all.

PERCA, the **PERACH**, in ichthyology, a genus belonging to the order of thoracici. The head is furnished with scaly and serrated opercula; there are seven rays in the membrane of the gills; and the fins on the back are prickly. There are 38 species, principally distinguished by peculiarities in the back fins.

PERCEPTION, in logic, the first and most simple act of the mind, whereby it perceives or is conscious of its ideas. See **LOGIC**.

PERCH. See **PERCA**.

PERCOLATION. See FILTRATION.

PERCUSSION, in mechanics, the impression a body makes in falling or striking upon another, or the shock of two bodies in motion.

PERDIX See TETRAO.

PERENNIAL, in botany, is applied to those plants whose roots will abide many years, whether they retain their leaves in winter or not : those which retain their leaves are called evergreens ; but such as cast their leaves, are called deciduous, or perdisols.

PERFORANS MANUS, in anatomy. See ANATOMY, p. 201.

PERFORANS PEDIS, in anatomy. See ANATOMY, p. 211.

PERFORATUS MANUS, in anatomy. See ANATOMY, p. 201.

PERFORATUS PEDIS, in anatomy. See ANATOMY, p. 211.

PERFUME, an agreeable odour, affecting the organ of smelling. The generality of perfumes are made up of musk, ambergrace, civet, rose and cedar-woods, orange-flowers, jassin, jonquils, tuberoses, and other odoriferous flowers. Those drugs commonly called aromatics, such as storax, frankincense, benzoin, cloves, mace, &c. enter the composition of a perfume : some are also composed of aromatic herbs or leaves, as lavender, marjoram, sage, thyme; hyssop, &c.

Perfumes were anciently very much in use : but since people are become sensible of the harm they do to the head, they are generally disused among us ; however, they are still common in Spain and Italy.

PERGA, a port-town of European Turkey, in the province of Albina, opposite to the island of Corfu, in E. long. 21°, N. lat. 39° 20'.

PERGAMUS, an ancient city of the lesser Asia, in the province of Phrygia, situated north of Smyrna.

PERIAGOGE, in rhetoric, is used where many things are accumulated into one period which might have been divided into several.

PERIANTHIUM, in botany. See BOTANY, p. 637.

PERICARDIUM, in anatomy. See ANATOMY, p. 279.

PERICARPIUM, among botanists. See BOTANY, p. 637.

PERICHORUS, in antiquity, a name given by the Greeks to their profane games and combats, that is, to such as were not consecrated to any of the gods.

PERICRANIUM, in anatomy. See ANATOMY, p. 288.

PERIGEE, in astronomy, that point of the sun's or moon's orbit wherein they are at their least distance from the earth, in which sense it stands opposed to apogee.

PERIGRAPHE, a word usually understood to express a careless or inaccurate delineation of any thing ; but in Vesalius it is used to express the white lines or impressions that appear in the musculus rectus of the abdomen.

PERIGUEUX, a city of France, in the province of Guienne, capital of the territory of Perigord, situated on the river Lisse : in E. long. 25°, N. lat. 45° 15'.

PERIHELIIUM, in astronomy, that point of a planet's or comet's orbit, wherein it is in its least distance from the sun ; in which sense it stands in opposition to aphelium.

PERIMETER, in geometry, the bonds or limits of any figure or body.

PERINÆUM, or PERINEUM, in anatomy, the space between the anus and the parts of generation, divided into

two equal lateral divisions, by a very distinct line, which is longer in males than in females.

PERIOD, in astronomy, the time taken up by a star or planet in making a revolution round the sun ; or the duration of its course till it return to the same point of its orbit.

See ASTRONOMY,

PERION, in grammar, denotes a small compass of discourse, containing a perfect sentence, and distinguished at the end by a point, or full stop, thus (.) ; and its members or divisions marked by commas, colons, &c.

PERIODIC, or PERIODICAL, something that terminates and comprehends a period ; such is a periodic month, being the space of time wherein the moon dispatches her period.

PERIOECI, in geography, such inhabitants of the earth, as have the same latitudes, but opposite longitudes ; or live under the same parallel, and the same meridian, but in different semicircles of that meridian, or in opposite points of the parallel.

PERIOPHTHALMIUM, in natural history. See NICOTITATING MEMBRANE.

PERIOSTEUM, in anatomy. See ANATOMY, p. 145.

PERIPATETIC PHILOSOPHY, that system taught and established by Aristotle, and maintained by his followers the peripatetics, called also Aristotelians.

PERIPETIA, in the drama, that part of a tragedy wherein the action is turned, the plot unravelled, and the whole concludes.

PERIPHERY, in geometry, the circumference of a circle, ellipsis, or any other regular curvilinear figure.

PERIPLOCA, in botany, a genus of the pentandria digynia class. The nectarium surrounds the inside of the flower, and includes the filaments and stili. There are four species, none of them natives of Britain.

PERIPNEUMONY, in medicine. See MEDICINE, p. 91.

PERISCIL, in geography, the inhabitants of either frigid zone, between the polar circles and the poles ; where the sun, when in the summer-signs, moves only round about them, without setting, and consequently their shadows, in the same day, turn to all the points of the horizon.

PERISTALTIC, a vermicular spontaneous motion of the intestines, performed by the contraction of the circular and longitudinal fibres, of which the fleshy coats of the intestines is composed ; by means whereof the chyle is driven into the orifices of the lacteal veins, and the feces are protruded towards the anus.

PERISTAPHYLINUS, in anatomy. See ANATOMY, p. 303.

PERISTYLE, in ancient architecture, a building encompassed with a row of columns on the inside.

PERISTOLE, the interval of rest between the two motions of the heart, viz. that of the systole or contraction, and that of the diastole or dilation.

PERITONÆUM, in anatomy. See ANATOMY, p. 257.

PERITROCHIUM, in mechanics, denotes a wheel, or circle, concentric with the base of a cylinder, and moveable together with it about an axis. See MECHANICS.

PERJURY, in law, the crime of swearing falsely, where a lawful oath is administered by one in authority, in a matter relating to the issue or cause in question, whether it be a person's own wilful act, or done by the subornation of others.

At the common law, perjury, and the subornation of

- it, are punishable by fine, imprisonment, pillory, transportation, &c. See *LAW*, Tit. xxxiii. 34.
- PERMEABLE**, a term applied to bodies of so loose and porous a structure, as to let something pass through them.
- PERMUTATION**, in commerce, the same with bartering. See *COMMERCE*.
- PERNAMBUCO**, a province of Brasil, in America, bounded by the province of Tamera on the north, by the Atlantic ocean on the east, by the province of Seregippa on the south, and by the country of the Tapuyers on the west; being two hundred miles long, and one hundred and fifty broad.
- PERONEUS**, in anatomy. See *ANATOMY*, p. 209.
- PERORATION**, in rhetoric, the epilogue, or last part of an oration, wherein what the orator had insisted on through his whole discourse, is urged afresh with greater vehemence and passion.
- PEROUSA**, a town of Italy, in the province of Piedmont, capital of one of the valleys of the Vaudois, situated twelve miles south-west of Turin.
- PERPENDICULAR**, in geometry, a line falling directly on another line, so as to make equal angles on each side. See *GEOMETRY*.
- PERPETUAL MOTION**. See *MOVEMENT*.
- PERPIGNAN**, a city of Spain, in the province of Catalonia, capital of the territory of Roussillon, situated on the river Latet: in E. long. $2^{\circ} 35'$, N. lat. 43° .
- PERRUKE**, or **PERRIWIG**, was anciently used for a head of long natural hair, particularly such as was curled and adjusted with great care. But it is now used for a set of borrowed hair, curled, baked, interwoven between four threads, and sewed together on a cawl.
- PERRY**, a drink made of pears, in the same manner as cyder is made from apples. See *CYDER*.
- PERSECUTION**, is any pain or affliction which a person designedly inflicts upon another; and, in a more restrained sense, the sufferings of Christians on account of their religion.
- Historians usually reckon ten general persecutions; the first of which was under the emperor Nero, thirty one years after our Lord's ascension; when that emperor having set fire to the city of Rome, threw the odium of that execrable action on the Christians, who under that pretence were wrapped up in the skins of wild beasts, and worried and devoured by dogs; others were crucified, and others burnt alive. The second was under Domitian, in the year 95. In this persecution St John the apostle was sent to the isle of Patmos, in order to be employed in digging in the mines. The third began in the third year of Trajan, in the year 100, and was carried on with great violence for several years. The fourth was under Antoninus the philosopher, when the Christians were banished from their houses, forbidden to wear

- their heads, reproached, beaten, hurried from place to place, plundered, imprisoned, and stoned. The fifth began in the year 197, under the emperor Severus. The sixth, began with the reign of the emperor Maximinus, in 235. The seventh, which was the most dreadful persecution that ever had been known in the church, began in the year 250, in the reign of the emperor Decius, when the Christians were in all places driven from their habitations, stripped of their estates, tormented with racks, &c. The eighth began in the year 257, in the fourth year of the reign of the emperor Valerian. The ninth was under the emperor Aurelian A. D. 274, but this was very inconsiderable: and the tenth began in the nineteenth year of Dioclesian, A. D. 303. In this dreadful persecution, which lasted ten years, houses filled with Christians were set on fire; and whole droves were tied together with ropes, and thrown into the sea.
- PERSEPOLIS**, formerly a city of Persia, but now in ruins. Here are the most magnificent remains of a palace, or temple, that are now in being on the face of the earth: E. long. 54° , N. lat. $30^{\circ} 30'$.
- PERSEUS**, in astronomy. See *ASTRONOMY*, p. 486.
- PERSIA**, a large kingdom of Asia, 1200 miles long, and almost as much broad; situated between 45° and 67° of E. long. and between 25° and 45° of N. lat. bounded by Circassian Tartary, the Caspian Sea, and the river Oxus, on the north; by India, on the east; by the Indian Ocean, and the gulphs of Ormus and Persia, on the south; and by the Turkish empire on the west.
- PERSICA**, in botany. See *AMYGDALUS*.
- PERSICARIA**, in botany. See *POLYGONUM*.
- PERSON**, an individual substance of a rational or intelligent nature. Thus we say, an ambassador represents the person of his prince; and that, in law, the father and son are reputed the same person.
- PERSON**, in grammar, a term applied to such nouns or pronouns, as, being either prefixed or underfoot, are the nominatives in all inflections of a verb; or it is the agent or patient in all finite and personal verbs. See *GRAMMAR*.
- PERSONAL RIGHT**, in Scots law. See *LAW*, Tit. xx. 1.
- PERSONAL VERB**, in grammar, a verb conjugated in all the three persons; thus called, in opposition to an impersonal verb, or that which has the third person only.
- PERSONALITY**, in the schools, that which constitutes an individual or distinct person.
- PERSONIFYING**, the giving an inanimate being the figure, sentiments, and language of a person.
- Personifying is essential to poetry, especially to the epopeia: the poets have therefore personified all the passions, and even represented them as deities; as the goddess Persuasion, the god Sleep; the Furies, Envy, Discord, and Fame, Fortune, Victory, Sin, Death, &c.

P E R S P E C T I V E.

PERSPECTIVE teaches how to represent objects on a plane superficies, such as they would appear at a certain distance and height, upon a transparent plane perpendi-

cular to the horizon, placed between the objects and the eye.

In order to understand this subject, a general knowledge of the principles of Optics is absolutely necessary. The foundation

of vision of perspective may be understood by supposing the pentagon ABDEF (Plate CXLIII. fig. 1.) were to be represented by the rules of perspective on the transparent plane VP placed perpendicularly on the horizontal plane HIR; dotted lines are imagined to pass from the eye C to each point of the pentagon, as CA, CB, CD, &c. which are supposed in their passage through the plane PV to leave their traces or vestigia in the points *a, b, d*, &c. on the plane, and thereby to delineate the pentagon *abdef*; which, as it strikes the eye by the same rays that the original pentagon ABDEF does, will be a true perspective representation of it.

The business of perspective, therefore, is to lay down geometrical rules for finding the points *a, b, d, e, f*, upon the plane; and hence also we have a mechanical method of delineating any object very accurately.

Perspective is either employed in representing the ichnographies or ground plots of objects; or the scenographies, or representations of the objects themselves.

But before we give any examples of either, it will be proper to explain some technical terms in regard to perspective in general: and first, the horizontal line is that supposed to be drawn parallel to the horizon through the eye of the spectator; or rather it is a line which separates the heaven from the earth, and which limits the sight. Thus, A, B, (*ibid.* fig. 2.) are two pillars below the horizontal line CD, by reason the line is elevated above them; in fig. 3, they are said to be equal with it, and in fig. 4, raised above it. Thus, according to the different points in view, the objects will be either higher or lower than the horizontal line. The point of sight A (*ibid.* fig. 5) is that which makes the central ray on the horizontal line *ab*; or, it is the point where all the other visual rays DD unite. The points of distance, C, C, are points set off in the horizontal line at equal distances on each side of the point of sight A; and in the same figure BB represents the base line, or fundamental line: EE is the abridgment of the square; of which D, D, are the sides; F, F, the diagonal lines, which go to the points of distance C, C. Accidental points are those where the objects end: these may be called negligently: because neither drawn to the point of sight, nor to those of distance, but meeting each other in the horizontal line. For example, two pieces of square timber G and H (*ibid.* fig. 6) make the points I, I, I, on the horizontal line; but go not to the point of sight K, nor to the points of distance C, C; these accidental points serve likewise for cafements, doors, windows, tables, chairs, &c. The point of direct view, or of the front, is when we have the object directly before us; in which case, it shews only the fore-side; and, if below the horizon, a little of the top; but nothing of the sides, unless the object be polygonous.

Thus the plan ABCD. (*ibid.* fig. 7.) is all in front, and if it were raised we should not see any thing of the sides AB or CD, but only the front AD: the reason is, that the point of view E being directly opposite thereto, causes a diminution on each side; which however is only to be understood where an elevation is the object; for if it be a plan, it shews the whole, as ABCD.

The point of oblique view, is when we see an object aside of us, and as it were afant, or with the corner of the eye; the eye, however, being all the while opposite to the point of sight; in which case, we see the object laterally, and it presents to us two sides or faces.

For instance, if the point of sight be in F, (*ibid.* fig. 8) the object GHK will appear athwart, and shew two faces GK and GH, in which case it will be a side point.

We shall now give some examples, by which it will appear, that the whole practice of perspective is built upon the foundation already laid down. Thus, to find the perspective appearance of a triangle ABC (*ibid.* fig. 9.) between the eye and the triangle draw the line DE, which is called the fundamental line; from 2 draw 2 V, representing the perpendicular distance of the eye above the fundamental line, be it what it will; and through V draw, at right angles to 2 V, HK parallel to DE: then will the plane DHKE represent the transparent plane on which the perspective representation is to be made. Next to find the perspective points of the angles of the triangle, let fall perpendiculars A 1, C 2, B 3, from the angles to the fundamental DE: set off these perpendiculars upon the fundamental opposite to the point of distance K, to B, A, C; from 1, 2, 3, draw lines to the principal point V; and from the points A, B, and C, on the fundamental line, draw the right lines AK, BK, CK, to the point of distance K, which is so called, because the spectator ought to be so far removed from the figure or painting, as it is distant from the principal point V. The points *a, b*, and *c*, where the visual lines V 1, V 2, V 3 intersect the lines of distance AK, BK, CK, will be the angular points of the angle *a b c*, the true representation of ABC.

To draw a square pavement in perspective. See fig. 10. and 11. of Plate CXLIII.

Suppose your piece of pavement to consist of 64 pieces of marble, each a foot square. Your first business is, to draw an ichnographical plan or ground-plot of it, which is thus performed. Having made an exact square of the size you intend your plan, divide the base and horizon into eight equal parts; and from every division in the base to its opposite point in the horizon, rule perpendicular lines: then divide the sides into the same number, ruling parallel lines across from point to point: so will your pavement be divided into 64 square feet; because the eight feet in length, multiplied by the same in breadth, give the number of square feet or pieces of marble contained in the whole: then rule diagonals from corner to corner; and thus will your ground-plot appear as in fig. 10.

Now, to lay this in perspective, draw another square to your intended size, and divide the base line AB into eight equal parts, as before; then fix your point of sight C in the middle of the horizon DE, and from the same point rule lines to every division in the base AB: after which, rule diagonal lines from D to B, and from E to A, answerable to those in the ground plot, and your square will be reduced to the triangle ABC; then from the point F, where the diagonal DB intersects the line AC, to the opposite intersection G, where the diagonal EA crosses the line CB, rule a parallel line, which is the abridgment of the square.

Then through the points where the diagonals cross the rest of the lines which go from the base to the point of sight, rule parallel lines, and your square pavement will be laid in perspective, as in fig. 11.

To diminish a square viewed by the angle D. See Plate CXLIII. fig. 12.

Having described the plane ABCD, draw a line to touch

or raise the angle B, and falling perpendicularly on BD.

This being continued as a base line, lay your ruler on the side of the square AD and DC, and where the ruler cuts the terrestrial line make the points H, I.

Then from H and B draw lines to the point of distance P, and from I draw a line to the other point of distance G; and in the intersection of those lines, make points, which will give you the square KLMB.

To do without the plan: set off the diameter each way from the middle point B, as to H and I. But in either case no line is to be drawn to the point of sight O.

To diminish a Circle. See Plate CXLIII. fig. 13.

Draw a square ABCD about it, and from the angles AD and CB draw diagonals, dividing the circle into eight parts, and through the points where they cut it OO, draw lines from the base line perpendicular to DEF.

Then draw two diagonals QR, SP, intersecting each other at right angles in the centre G.

Having thus disposed the plan, draw lines from all the perpendiculars to the point of sight H; and where they are intersected by the diagonals AK and BI, make points; the two last of which M, N give the square, which is to be divided into four by diagonals, intersecting each other in the point P.

In the last place, from the extremes of this cross, draw curve lines through the said points, which will give the form of the circle in perspective.

Of the measures upon the base in perspective. Pl. CXLIV.

By the base line alone any depth may be given, and in any place at pleasure, without the use of squares; which is a very expeditious way.

As for example, suppose the base line BS, (fig. 1.) the point of view A, and the points of distance DE; if now you would make a plan of a cube BC, draw two occult or dotted lines from the extremes BC to the point of sight; then to give the breadth, take the same measure BC, and set it off on the terrestrial line CF, and from F draw a line to the point of distance D; and where this line intersects the first ray C in the point G, will be the diminution of the plan of the cube BHGC.

If you would have an object farther towards the middle, take the breadth, and the distance of the base line, as IK; and to have the depth, set it as you would have it on the same base as LM, and its width both on LM. Then from L and M draw occult lines to the point of distance D, and from the points NO, where those lines intersect the ray K, draw parallels to the terrestrial line, and you will have the square QPON.

After the same manner you may set off the other side of the square which should be on the base, as BHGC is here transferred to V. The points M and T, which are only two feet from the point S, afford a very narrow figure in X, as being very near.

Of the base line, and a single point of distance.

Since the depths and widths may be had by the means of this base line, there is no need of any further trouble in making of squares; as shall be shewn in this example.

Suppose a row of trees or columns is to be made on each side; on the base line lay down the place, and the distance between them, with their breadth or diameters, as ABC-

DEFG; then laying a ruler from the point of distance O to each of the points ABCDEFG, the intersections it makes on the visual ray AH will be the bounds of the objects desired. Fig. 2.

To set them off on the other side upon the ray GH, set one foot of the compasses upon the point of the eye H, and with the other strike an arch; the point wherein this cuts the ray GH, will be the corresponding bound.

Thus M will be the same with N, and so of the rest; through which drawing parallels, you will have the breadth.

And as for the length, you may make it at pleasure: setting it off from A, as for instance, to P, and then from P drawing a line to H; and where this cuts the other parallels, will be formed the plan required; which you may make either round or square.

To find the height and proportion of any objects, as they appear above the horizon on a supposed plane. See Plate CXLIV. fig. 3.

First rule your horizontal line NO, and fix your point of sight, as at M; then mark the place of your nearest pillar, by making a dot for the base or bottom, as at A; and another for the summit or top, as at B: rule a line from A to the point of sight M, and another from B to M, and these two lines will give the height of any number of pillars. As for example: Suppose you would have a pillar at C, fix your dot for the base, and rule from thence a parallel line to meet the diagonal AM at D: then rule the perpendicular DE to the diagonal BM: which perpendicular is the height of your figure required at C. Or, if you would place pillars at F and I, observe the same method, ruling the parallels FG and IK, and the perpendiculars GH and KL will give their heights at the distances required.

To find the diameter or thickness of pillars at any particular distances, you are also to be guided by that nearest the base. For instance: Suppose your nearest pillar AB to be ten feet high, and one foot in diameter: divide it from top to bottom into ten equal parts, and set off one of them upon the base of the pillar: then rule a line from the point of sight M to the diameter P, and you will have the thickness of all your pillars on their respective parallels or bases.

The same rule exemplified in objects below the horizon.

See Plate CXLIV. fig. 4.

If you would know the heights of a number of figures below the horizon, rule your horizontal line QR, and fix your point of sight, as at P: then place your nearest figure, or mark the dots for the head and feet, by the points A and B, which answers the same purpose; and rule from these dots to the point of sight the lines AP and BP: and if you would find the height of a figure to be drawn at c, rule from thence the parallel cd to the diagonal BP, and the perpendicular de will give the height required. The same directions will shew the height of a figure at any other distance you have a mind to place it, as at f, i, and m, by ruling the parallels fg, ik, and mn; and from each of these their respective perpendiculars gh, kl, and no; which perpendiculars will shew the heights of the figures at f, i, and m.

4. *To draw a direct view.* See Plate CXLIV. fig. 4.

To illustrate this example, suppose you were to draw the inside of a church, as represented in this figure: First take your station at the point A, in the centre of the base line

BC: from which you have a front view of the whole body of the church, with all the pillars, &c. on each side: then fix your horizon at any height you think proper, as at DE: bisect it by the perpendicular EA: and where these two lines intersect, is the point of sight F. This perpendicular will pass through the centres of all the arches in the dome or cupola: which centres may be found by any three given points. Next divide your base line into any given number of feet; and the visual lines, ruled from these divisions to the point of sight, will reduce all your objects to their just proportion, by setting off their height upon a perpendicular raised at their respective distances. The base, in the example here given, is divided into twelve equal parts of five feet each; from which (supposing your front column to be 35 feet high) take seven divisions from the base line of your drawing, and set them off upon the perpendicular GH; then (supposing this column to be five feet thick at the base) set off one of those divisions upon the parallel IK, which is the breadth required. So that, by proportioning this scale to any distance by the foregoing directions, you may not only find the dimensions of all your columns, but also of every distinct part of them, as well as of all the doors, windows, and other objects that occur. For instance: Having found the height and breadth of your first or nearest column G, draw from the top and bottom of the said column to the point of sight the lines HF and KF; after which, rule the line IF from the base of the column to the point of sight, and you have the height and breadth of all the rest of the columns, as has been already shewn in fig. 3.

By ruling lines from the points *a, b, c, d*, &c. to the point of sight, you will see that all the summits and bases of your columns, doors, windows, &c. must tend immediately to that point; and by lines drawn from the points 1, 2, 3, 4, &c. on each side, to the correspondent points on the opposite side, may be seen all the parts of your building lying upon the same parallel.

To draw an oblique view. See fig. 6. of Plate CXLIV.

First draw your horizontal line AB; then, if your favourite object be on the right hand, as at C, place yourself on the left hand upon the base line, as at D; then from that station erect a perpendicular DE, which will pass through the horizon at the point of sight F; to which rule the diagonals CF and HF, which will shew the roof and base of your principal building C, and will also, as before directed, serve as a standard for all the rest.

Observe also, either in direct or oblique views, whether the prospect before you make a curve; for if it does, you must be careful to make the same curve in your drawing.

To draw a perspective view, wherein are accidental points. See fig. 7. of Plate CXLIV.

Rule your horizontal line *ab*, and on one part of it fix your point of sight, as at *c*; from which rule the diagonals *cd* and *ce* on the one side, and *cf* and *cg* on the other; which will shew the roofs and bases of all the houses in the street directly facing you; (supposing yourself placed at A in the centre of the base line.) Then fix your accidental points *g* and *h* upon the horizontal line, and rule from them to the angles *ik* and *lm*, (where the streets on each side take a different direction, towards the accidental points *g* and *h*) and the lines *gi* and *gh* give the roofs and bases of all the buildings on one side, as *li* and *mh* do on the other.

Accidental points seldom intervene where the distance is small, as in noblemans seats, groves, canals, &c. which may be drawn by the strict rules of perspective: but where the prospect is extensive and varied, including mountains, bridges, castles, rivers, precipices, woods, cities, &c. it will require such an infinite number of accidental points, that it will be better to do them as nature shall dictate, and your ripened judgment approve.

To find the centre for the roof of a house, in an oblique view. See fig. 8. of Plate CXLIV.

Suppose from the point of sight A, the visual lines AB and AC be drawn, BC being one perpendicular given, and DE the other, rule the diagonals from D to C, and from E to E, and the perpendicular FG, raised through the point of their intersection, will shew the true centre of the roof, as will appear by ruling the lines GE and GC.

For want of being acquainted with this necessary rule, many who have been well versed in other parts of perspective, have spoiled the look of their picture, by drawing the roofs of their houses out of their true perpendicular.

WE shall conclude by giving a few practical rules. 1. Let every line, which in the object, or geometrical figure, is straight, perpendicular, or parallel to its base, be so also in its scenographic delineation. 2. Let the lines, which in the object return at right angles from the fore-right side, be drawn scenographically from the visual point. 3. Let all straight lines, which in the object return from the fore-right side, run in a scenographic figure into the horizontal line. 4. Let the object you intend to delineate, standing on your right-hand, be placed also on the right hand of the visual point; and that on the left-hand, on the left-hand of the same point; and that which is just before, in the middle of it. 5. Let those lines which are (in the object) equidistant to the returning line be drawn in the scenographic figure, from that point found in the horizon. 6. In setting off the altitude of columns, pedestals, and the like, measure the height from the base line upwards, in the front or fore-right side; and a visual ray down that point in the front shall limit the altitude of the column or pillar, all the way behind the fore-right side, or orthographic appearance, even to the visual point. This rule you must observe in all figures, as well where there is a front or fore-right side, as where there is none. 7. In delineating ovals, circles, arches, crosses, spirals, and cross-arches, or any other figure in the roof of any room, first draw ichnographically, and so with perpendiculars from the most eminent points thereof, carry it up unto the ceiling; from which several points, carry on the figure. 8. The centre in any scenographic regular figure is found by drawing lines from opposite angles: for the point where the diagonals cross, is the centre. 9. A ground-plane of squares is alike, both above and below the horizontal line; only the more it is distant above or beneath the horizon, the squares will be so much the larger or wider. 10. In drawing a perspective figure, where many lines come together, you may, for the directing of your eye, draw the diagonals in red; the visual lines in black; the perpendiculars in green, or other different colour, from that which you intend the figure shall be of. 11. Having considered the height, distance, and position of the figure, and drawn it accordingly, with side or angle against the base; raise perpendiculars from the several angles,

Fig. 13.

or designed point, from the figure to the base, and transfer the length of each perpendicular, from the place where it touches the base, to the base on the side opposite to the point of distance; so will the diametrals drawn to the perpendiculars in the base, by intersection with the diagonals, drawn to the several transferred distances, give the angles of the figures, and so lines drawn from point to point will circumscribe the scenographic figure. 12. If in a landscape there be any standing-waters, as rivers, ponds, and the like, place the horizontal line level with the farthest light or appearance of it. 13. If there be any house, or the like, in the picture, consider their position, that you may find from what point in the horizontal lines to draw the front and sides thereof. 14. In describing things at a great distance, observe the proportion, both in magnitude and distance, in draught, which appears from the object to the eye. 15. In colouring and shadowing of every thing, you must do the same in your picture, which you observe with your eye, especially in objects lying near; but, according as the distance grows greater and greater, so the colours must be fainter and fainter, till at last they lose themselves in a darkish sky-colour. 16. The catoptrics are best seen in a common looking-glass, or other polished matter; where, if the

glass be exactly flat, the object is exactly like its original; but, if the glass be not flat, the resemblance alters from the original; and that more or less, according as the glass differs from an exact plane. 17. In drawing catoptric figures, the surface of the glass is to be considered, upon which you mean to have the reflection: for which you must make a particular ichnographical draught, or projection; which on the glass must appear to be a plane full of squares, on which projection transfer what shall be drawn on a plane, divided into the same number of like squares; where though the draught may appear very confused, yet the reflection of it on the glass will be very regular, proportional, and regularly composed. 18. The dioptric, or broken beam, may be seen in a tube through a crystal or glass, which hath its surface cut into many others, whereby the rays of the object are broken. For to the flat of the crystal, or water, the rays run straight; but then they break and make an angle, which also by the refracted beams is made and continued on the other side of the same flat. 19. When these faces on a crystal are returned towards a plane placed directly before it, they separate themselves at a good distance on the plane; because they are all directed to various far distant places of the same. See OPTICS.

P E R

PERSPECTIVE GLASS, in optics, differs from a telescope in this: instead of the convex eye-glass placed behind the image, to make the rays of each pencil go parallel to the eye, there is placed a concave eye-glass as much before it; which opens the converging rays, and makes them emerge parallel to the eye. See OPTICS.

PERSPIRATION, in medicine, the evacuation of the juices of the body through the pores of the skin. Perspiration is distinguished into sensible and insensible: and here sensible perspiration is the same with sweating, and insensible perspiration that which escapes the notice of the senses; and this last is the idea affixed to the word perspiration when used alone.

The matter of insensible perspiration, is a fine subtle fluid, which exhales from the body in the form of a vapour, and proceeds from the whole surface and from every cavity; it is of an aqueous and saline nature, and seems to have a great analogy with urine; because in a healthy state, the increase of the one diminishes the other. Many experiments prove its existence. Sanctiorius found, in Italy, under the circumstances of a moderate diet, middle age, and easy life, that the matter insensibly perspired was five-eighths of that taken in for food; so that there only remained three-eighths for nutrition, and for the excrements of the nose, ears, intestines, bladder, &c. The same author shews, that as much is evacuated by perspiration in one day, as by stool in fourteen days.

But Dr. Bryan Robinson, of Dublin, has found the case very different, both in England and Ireland, and even in South Carolina, in all which places he found that the quantity of urine exceeds that of perspiration; and that if the meat and drink of one day be four pounds and a half, the perspiration of that day will be two pounds, the urine two pounds five ounces, and the stool three ounces.

P E S

The matter of sweat is separated from the blood by the military glands, and is therefore much more gross than that of insensible perspiration; for as there are no glands which serve for the excretion of this last fluid, it is supposed to proceed from the extremities of the capillary arteries.

The use of perspiration is to preserve the suppleness of the papillæ of the skin; to carry the saline particles off from the blood, and by this means to render it more pure; to preserve the body from various diseases; and to contribute to the cure of the most dangerous distempers. It may be promoted by exercise, by dry frictions with a coarse linen-cloth or a flesh-brush, by warm baths, and washing the hands, feet, head, &c.

PERTH, the capital of the county of the same name in Scotland, thirty miles north of Edinburgh.

PERTHAMBOY, a port-town of New-Jersey, in North America: W. long. 74°. N. lat. 40° 45'.

PERTINENT OF LANDS, in Scots law. See LAW, Tit. xiii. 18.

PERU, formerly a powerful empire in South America, but now a province of Spain, is situated between 60° and 81° of west longitude, and between the equator and 25° of south latitude, being near 2000 miles in length from north to south, and from 200 to 500 broad: it is bounded by Popayan, on the north; by the mountains of Andes, on the east; by Chili and La Plata, on the south; and by the Pacific Ocean, on the west.

PERUGIA, a city of Italy, in the territories of the pope: E. long. 13° 16'. N. lat. 43°.

PERUVIAN BARK. See CINCHONA.

PESARO, a city of Italy, in the province of Urbino, situated on the gulph of Venice: E. long. 14°. N. lat. 44°.

PESSARY, in medicine, a solid substance composed of wool, lint, or linen, mixed with powder, oils, wax, &c. made.

made round and long like a finger, in order to be introduced into the exterior neck of the matrix, for the cure of several disorders incident to the uterus.

PEST, a city of upper Hungary, situated on the Danube: E. long. $19^{\circ} 15'$ N. lat. $47^{\circ} 42'$.

PESILENCE, in medicine. See **MEDICINE**, p. 71.

PETAL, among botanists. See **BOTANY**, p. 637.

PETALISM, in antiquity, a kind of banishment practised at Syracuse, by writing the person's name on a leaf; whence the name.

PETARD, in the art of war. See **GUNNERY**, p. 761.

PETACITES, in botany. See **TUSILAGO**.

PETECHIÆ, in medicine, denotes spots in the skin like flea-bites, which come out in malignant fevers, hence called petechial or spotted fevers. See **MEDICINE**, p. 67.

PETER, or *Epistles of St. Peter*, two canonical books of the New Testament, written by the apostle St. Peter, and addressed to those Jewish converts who were scattered throughout Pontus, Galatia, &c. not only upon the persecution raised at Jerusalem, but upon former dispersions of the Jews into those places. The first of these epistles is principally designed to comfort and confirm them, under those fiery trials they were then subject to; and to direct them how to behave in the several states and relations, both of the civil and the Christian life. In the second epistle, the apostle prosecutes the same subject, to prevent their apostasy from the faith, and guard them against the corrupt principles of the gnostics, and those who scoffed at the promise of Christ's coming.

St. Peter's Day, a festival of the Christian church, observed on the twenty-ninth of June.

PETERBOROUGH, a city of Northamptonshire, situated on the river Nene, thirty-four miles north-east of Northampton: W. long. $15'$ N. lat. $52^{\circ} 53'$. It sends two members to parliament.

PETER-PENCE, an ancient tax of a penny on each house, paid to the pope.

It was called peter-pence because collected on the day of St. Peter *ad vincula*, and sent to Rome; whence it was also called Rome-fee and Rome-penny.

PEIERSBURG, the capital city of Russia, and one of the largest and most populous cities in the world, situated on both sides the river Nieva, in the provinces of Carelia and Ingria, between the gulph of Finland and the lake of Ladoga: E. long. 31° N. lat. 60° . There were no less than sixty-five thousand houses built within three or four years after the foundation was laid, which was in the year 1703.

PETERSFIELD, a borough-town of Hampshire, fifteen miles south-east of Winchester.

PETERSHAGEN, a town of Germany, in the circle of Westphalia and duchy of Minden, thirty-seven miles west of Hanover: subject to Prussia.

PETHERTON, a market-town of Somersetshire, 16 miles south-west of Wells.

PETIOLE, in botany, the slender stalks that supports the leaves of a plant.

PETITGUAVES, a port-town of Hispaniola, situated on a bay at the west end of the island: W. long. 76° N. lat. $18^{\circ} 5'$: subject to France.

PETITIO PRINCIPII, in logic, the taking a thing for true, and drawing conclusions from it as such; when it

is really false, or at least wants to be proved, before any inferences can be deduced from it.

PETITORY ACTION, in Scots law. See **LAW**, Tit. xxx. 18.

PETITIVERIA, in botany, a genus of the hexandria tetragynia class. The calix consists of four segments; it has no corolla; and but one seed with reflected prickles at the point. There are two species, none of them natives of Britain.

PETRE, or **SALT-PETRE**. See **CHEMISTRY**, p. 73, 119.

PETREA, in botany, a genus of the didynamia angiospermia class. The calix is large, open, coloured, and divided into five segments; the corolla is open and rotated. There is but one species, a native of America.

PETRIDIA, in natural history, a genus of scrapi, of a plane, uniform structure, of no great variety of colours, and emulating the external form of pebbles.

PETRIFACTION, in physiology, denotes the conversion of wood, bones, and other substances into stone.

The fissile bodies found petrified are principally either of vegetable or animal origin, and are more or less altered from their original state, according to the different substances they have lain buried among in the earth; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone or lumps of the matter of the common pyrites; but they are generally of the external dimensions, and retain more or less of the internal figure of the bodies into the pores of which this matter has made its way.

The animal substances thus found petrified are shells; the teeth, bony palates, and bones of fish; the bones of land animals, &c. These are found variously altered, by the insinuation of stony and mineral matter into their pores; and the substance of some of them is now wholly gone, there being only stony, sparry, or other mineral matter remaining in the shape and form.

PETROBRUSSIANS, in church-history, a religious sect which arose in France and the Netherlands, about the year 1126, so called from their leader Peter Bruys. They denied that children, before the use of reason, can be justified by baptism. They also condemned all places of public worship, crosses, crucifixes; and are said to have rejected the sacrament of the eucharist, and prayers for the dead.

PETROLEUM, also called rock-oil, is an extremely subtle and penetrating fluid, and is much the thinnest of all the native bitumens. It is very light and very pellucid; but though equally bright and clear under all circumstances, it is liable to a very great variety in its colour. It is naturally almost colourless, and in its appearance greatly resembles the most pure oil of turpentine: this is called white petroleum, though it has no more colour than water; it is sometimes tinged of a brownish, reddish, yellowish, or faint greenish colour; but its most frequent colour is a mixture of the reddish and blackish, in such a degree that it looks black when viewed behind the light, but purple when placed between the eye and a candle or window. It is of a pungent and acrid taste, and of a very strong and penetrating smell, which very much approaches to that of the distilled oil of amber. The white

is most esteemed. It is so very inflammable, that while it floats on the surface of the water, as it does in many parts of Italy, it takes fire at the approach of a candle.

Petroleum is found in rivers, in wells, and trickling down the sides of hills along with little streams of water. In short, it is the most frequent of all the liquid bitumens, and is perhaps the most valuable of them all in medicine. It is to be chosen the purest, lightest, and most pellucid that can be had, such as is of the most penetrating smell and is most inflammable.

It is principally used externally, in paralytic cases, and in pains of the limbs.

PETROMYZON, in ichthyology, a genus belonging to the amphibia nantes class. It has seven spiracula at the side of the neck, no gills, a fistula on the top of the head, and no breast or belly fins. There are three species, distinguished by peculiarities in the back fins.

PETROSA ossa, in anatomy. See **ANATOMY**, p. 295, &c.

PETTAU, a city of Germany, in the circle of Austria: E. long. 16° 8', N. lat. 47°.

PETTIPOLI, a port-town on the coast of Cormandel, in the hither India, where the Dutch have a factory: E. long. 80°, N. lat. 16° 45'.

PETUNSE, in natural history, one of the two substances whereof the porcelain or china-ware is made.

The petunse is a coarse kind of flint or pebble, the surface of which is not so smooth, when broken, as that of our common flint.

PEUCEDANUM, in botany, a genus of the pentandria digynia class. The fruit is oval, streaked on each side, and surrounded with a wing; and the involucrem is very short. There are five species, two of them natives of Britain, viz. the officinale, or hogs-fennel, the root of which is recommended in disorders of the breast; and the minus, or rock-parley.

PEWTER, a fictitious metal, used in making domestic utensils, as plates, dishes, &c.

The basis of this metal is tin, which is converted into pewter, by mixing at the rate of an hundred weight of tin with fifteen pounds of lead and six pounds of brass. See **METAL**.

Besides this composition, which makes the common pewter, there are other kinds compounded of tin, regulus of antimony, bismuth and copper, in several proportions.

PEZZIA, in botany, a genus of the cryptogamia fungi class. It is sessile and bell shaped. There are eight species, six of them natives of Britain.

PHACA, in botany, a genus of the diadelphia decandria class. The legumen or pod is somewhat bilocular. There are three species, none of them natives of Britain.

PHÆNOMENON, in philosophy, denotes any remarkable appearance, whether in the heavens or on earth; and whether discovered by observation or experiments.

PHAGEDÆNA, denotes a corroding ulcer.

PHAGEDÆNIC MEDICINES, those used to eat of fungous or proud flesh: such are all the caustics.

PHALÆNA, in zoology, a genus of insects belonging to the order of lepidoptera. The feelers are setaceous, and taper gradually to the points; the wings are often bent backwards; and the species of this genus fly about in the

night. There are no less than 460 species, comprehending all the moths.

PHALANGIUM, in zoology, a genus of insects belonging to the order of aptera. They have eight feet, two eyes on the top of the head placed very near each other, and other two on the sides of the head; the feelers resemble legs; and the belly is round. There are nine species.

PHALANGIUM, in botany. See **ANTHERICUM**.

PHALANX, in Grecian antiquity, a square battalion, consisting of eight thousand men, with their shields joined, and pikes crossing each other; so that it was next to impossible to break it.

PHALARIS, in botany, a genus of the triandria digynia class. It has two carinated valves, of equal lengths, and including the corolla. There are 10 species, three of them natives of Britain, viz. the canariensis, or manured canary-grass; the arenaria, or sea canary-grass; and the arundinaria, or reed canary-grass.

PHALEUCIAN verse, in ancient poetry, a kind of verse which consists of five feet, the first of which is a spondee, the second a dactyl, and the three last trochees.

PHALLUS, in botany, a genus of the cryptogamia fungi class. It is woven like a net above, and smooth below. There are two species, both natives of Britain, viz. the esculentus, or esculent morel; and the impudicus, or stinking morel.

PHANATIC, or **FANATIC**, a term of reproach formerly given to the dissenters, from a false supposition that they pretended to visions, &c.

PHANTASM, a term sometimes used in a synonymous sense with idea, or the notion retained in the mind of an external object.

PHARISEES, a famous sect of the Jews, who distinguished themselves by their zeal for the traditions of the elders, which they derived from the same fountain with the written word itself; pretending that both were delivered to Moses from Mount Sinai, and were therefore both of equal authority. From their rigorous observance of these traditions, they looked upon themselves as more holy than other men, and therefore separated themselves from those whom they thought sinners or prophane, so as not to eat or drink with them; and hence, from the Hebrew word *pharis*, which signifies to separate, they had the name of Pharisees or Separatists.

PHARMACY, the art which teaches the election, preparation, and mixture of medicines; constituting one part of the therapeutic branch of medicine, the objects of which are all natural bodies.

PHARNACEUM, in botany, a genus of the pentandria trigynia class. The calix consists of five leaves; it has no corolla; and the capsule has three cells, containing many seeds. There are five species; none of them natives of Britain.

PHAROS, a small island in the mediterranean sea, opposite to Alexandria, in Egypt.

PHAROS, or **PHARE**, a **LIGHT-HOUSE**, a pile raised near a port, where fire is kept burning in the night, to guide and direct vessels near at hand.

PHARSALUS, a town of ancient Thessaly, situated in European Turkey, a little south of Larissa, in E. lon. 23°, and N. lat. 39°.

PHARYNX, in anatomy. See ANATOMY, p. 302.

PHASCUM, in botany, a genus of the cryptogamia musci class. The antheræ are operculated, and the calyptra is wanting. There are four species, all natives of Britain.

PHASEOLOUS, in botany, a genus of the diadelphia decandria class. The carina, stamina, and stylus, are twisted like a screw. There are 13 species, none of them natives of Britain.

PHASES, in astronomy, the several appearances or quantities of illumination of the moon, venus, mercury, and the other planets. See ASTRONOMY.

PHASIANUS, in ornithology, a genus belonging to the order of gallinæ. The cheeks are covered with a smooth naked skin. There are six species, viz. 1. The gallus, or dunghill cock and hen, with a compressed caruncle or fleshy comb on the top of the head, and a couple of caruncles or wattles under the chin; the ears are naked; and the tail is compressed, and erected. This bird, though now one of the domestic fowls, was originally brought from the East-Indies. They feed upon grain, grass-seeds, and worms. The cock or male is perhaps the boldest and most heroic of all the feathered tribe. He claps his wings before he sings or crows. He begins to crow about midnight, and seldom ceases till break of day. He is so exceedingly salacious, that one cock is sufficient for 10 hens. His sight is very piercing, and he never fails to cry in a peculiar manner when he discovers any bird of prey in the air. The hen is very prolific: she makes her nest on the ground; and the young, immediately after they are hatched, follow her, and pick up their food themselves. There are six or eight varieties of this species. 2. The motmot, or Guinea pheasant, is brownish, somewhat red below, with a wedge-like tail, and wants spurs. It is a native of Guinea and Brazil. 3. The colchicus, is red, with a blue head, a wedge-shaped tail, and papillous cheeks. It is a native of Asia. 4. The argus is yellowish, with black spots, a red face, and a blue crest on the back part of the head. It is found in Chinese Tartary. 5. The pictus, has a yellow crest, a red breast, and a wedge-shaped tail. It is a native of China. 6. The nycthemerus, is white, with a black crest and belly, and a wedge-shaped tail. It is a native of China. See Plate CXLII.

PHASMATA, in physiology, certain appearances arising from the various tinctures of the clouds, by the rays of the heavenly luminaries, especially the sun and moon. These are infinitely diversified by the different figures and situation of the clouds, and the appulses of the rays of light.

PHASSACHATES, in natural history, the name of a species of agate, which the ancients, in its different appearances, sometimes called also leucachates and perileucos. See AGATE.

PHEASANT, in ornithology. See PHASIANUS.

PHELLANDRIUM, in botany, a genus of the pentandria digynia class. The fruit is oval and smooth. There are two species, one of them, viz. the aquaticum, or water hemlock, is a native of Britain.

PHELYPEA, in botany. See LATHRÆA.

PHENICIA, a subdivision or province of Syria, situated on the Levant, or eastern part of the Mediterranean sea, on the confines of Palestine.

PHEONS, in heraldry, the barbed heads of darts, arrows,

or other weapons, and usually represented as in Plate CXLV. fig. 1.

PHIDITIA, in Grecian antiquity, feasts celebrated with great frugality at Lacedæmon. The phiditia were held in the public places, and in the open air: rich and poor assisted at them alike, and on the same footing; their design being to keep up peace, friendship, and a good understanding and equality among all the citizens, great and small. It is said, that they who attended this feast, brought each a bushel of flour, eight measures of wine named chorus, five minæ of cheese, and as much figs.

PHILADELPHIA, the capital of the province of Pensilvania, in North America, situated on the rivers Delaware and Schuylkill: W. long. 74°, N. lat. 40° 50'.

PHILADELPHIA is also the name of an ancient town of the Lesser Asia, situated in E. long. 29°, N. lat. 38°.

PHILADELPHUS, in botany, a genus of the icofandria monogynia class. The calix consists of four or five segments, and the corolla of four or five petals; and the capsule has four or five cells, containing many seeds. There are two species, none of them natives of Britain.

PHILIP-FORT, a fortress in Dutch Brabant, situated on the east side of the Scheld, opposite to Pearl-fort, five miles north-west of Antwerp.

PHILIPPI, an ancient town of Macedonia, a province of European Turkey, situated in E. long. 25°, N. lat. 41°.

PHILIPPICS, in literature, a name given to the orations of Demosthenes against Philip king of Macedon; being esteemed the master-pieces of that great orator.

Philippic is also a term applied to the fourteen orations of Cicero against Mark Anthony.

PHILIPPINE ISLANDS, are situated in the Pacific ocean, in Asia, between 114° and 131° east longitude, and between 5° and 19° north latitude: there are a great number of them, and some very large.

PHILIPPINES, a religious society of young women, at Rome; so called from their taking St. Philip de Neri for their protector: they consist of an hundred poor girls, who are brought up till they are of age to be married, or become nuns, under the direction of some religious women, who teach them to read, write, and work; and instruct them in the duties of Christianity. They wear a white veil, and a black cross on their breasts.

PHILIPPOPOLI, a city of European Turkey, in the province of Romania, situated on the river Mariza: in E. long. 25°, and N. lat. 42° 20'.

PHILIPSBURGH, a city of Germany, in the palatinate of the Rhine. situated on the east bank of the river Rhine, in E. long. 8° 16', N. lat. 49° 8'.

PHILIPSTAT, a town of Sweden, in the province of Gothland and territory of Wermeland, situated in E. long. 14°, N. lat. 59° 50'.

PHILLYREA, in botany, a genus of the diandria monogynia class. The corolla consists of four segments, and the berry contains four seeds. There are three species, none of them natives of Britain.

PHILOLOGY, a science, or rather assemblage of several sciences, consisting of grammar, rhetoric, poetry, antiquities, history, and criticism.

Philology is a kind of universal literature, conversant about all the sciences, their rise, progress, authors, &c. It makes what the French call the *belles lettres*.

PHILOMATHES, a lover of learning or science.

PHILONIUM,

PHILONIUM, in pharmacy, a kind of somniferous anodyne opiate, taking its name from Philo the inventor.

PHILOSOPHER, a person versed in philosophy; or one who makes profession of, or applies himself to, the study of nature and morality.

PHILOSOPHER'S STONE, the greatest object of alchemy, is a long sought for preparation, which, when found, is to convert all the true mercurial part of metal into pure gold, better than any that is dug out of the mines, or perfected by the refiner's art; and this only by calling a little quantity thereof upon metals in fusion, whilst that part of the metal which was not mercury is immediately burnt or blown away. But this, like every other scientific chimera, will for ever elude the researches of mankind.

PHILOSOPHIC, or **PHILOSOPHICAL**, something that relates to philosophy. See **PHILOSOPHY**.

PHILOSOPHICAL EGG, among chemists, a thin glass-body, or bubble, of the shape of an egg, with a long neck or stem, used in digestions.

PHILOSOPHY, the knowledge or study of nature and morality, founded on reason and experience. See **MECHANICS**, **OPTICS**, **ASTRONOMY**, **LOGIC**, **MORALS**, &c.

PHILYCA, in botany, a genus of the pentandria monogynia class. The perianthium is turbinate, and divided into five segments; it has no petals, but five scales fortifying the stamina. There are six species, none of them natives of Britain.

PHIMOSIS, in medicine, a disorder of the penis, in which the prepuce is rendered so strict or tense, that it cannot be drawn back over the glans. See **MEDICINE**.

PHLEBOTOMY, the opening a vein with a proper sharp-edged and pointed instrument of steel, in order to let out a proper quantity of blood, either for the preservation or recovery of a person's health.

PHLEGM, in the animal œconomy, one of the four humours whereof the ancients supposed the blood to be composed.

The chemists make phlegm, or water, an elementary body, the characters of which are fluidity, insipidity, and volatility.

PHLEGMAGOGUES, in pharmacy, such medicines as purge off phlegm: such are hermodactyls, agaric, turbith, jalap, &c.

PHLEGMATIC, among physicians, an appellation given to that temperament, or habit of the body, wherein phlegm is predominant; which gives rise to catarrhs, coughs, &c.

PHLEGMON, denotes an external inflammation and tumour, attended with a burning heat, &c.

PHLEUM, in botany, a genus of the triandria digynia class. The calix consists of two linear, truncated valves; there are five species, three of them natives of Britain, viz. the pratense, or meadow cat's-tail-grass; the paniculatum, or branched cat's-tail-grass; and the nodosum, or bull's-eye cat's-tail-grass.

PHLOGIDIAUGIA, a class of fossils, the characters of which are, that the bodies comprehended in it are transparent and inflammable: such are sulphur, orpiment, zarnick, and amber.

PHLOGISCERIA, another class of fossils, which are inflammable bodies of a coarser and more impure texture,

and not pellucid: such are ambergrease, jet, asphaltum, ampelites, and lithanthrax.

PHLOGISTON. See **CHEMISTRY**, p. 68.

PHLOGONIAE, a class of compound, inflammable, and metallic fossils, found in small masses of determinately angular figures; comprehending the pyricubia, pyroctogonia, and pyripolygonia.

PHLOMIS, in botany, a genus of the didynamia gymnospermia class. The calix is angular; and the superior lip of the corolla is compressed, incumbent, and hairy. There are twelve species, none of them natives of Britain.

PHLOX, in botany, a genus of the pentandria monogynia class. The corolla is shaped like a jug; the filaments are unequal; the stigma is trisid; and the capsule has three cells, and contains but one seed.

PHLYCTÆNE, in medicine, small eruptions on the skin.

PHOCA, in zoology, a genus of quadrupeds of the order of the feræ. It has six parallel fore-teeth in the upper jaw, the outermost being larger; and four blunt, parallel, distinct, equal fore-teeth in the under jaw: It has but one dog-tooth, and five or six three-pointed grinders; and the hind-feet are united so as to resemble a fish's tail. There are three species, viz. 1. The urfina, or sea-bear, has external ears. This animal swims with incredible swiftness: The males have often 120 females, sons, and daughters, in their train. They copulate on the shore, the female lying on their backs. They are hardly afraid of men, and bite stones when thrown at them. Each has a particular stone for his bed, which they seldom desert. They often fight for their wives and beds; when one is beat off, another makes a fresh attack, and thus succeed alternately, two never attacking one, till the whole be engaged, when they make a hideous wailing noise. They are found in the northern seas. 2. The leonina, or sealion, has a crest on his forehead. They are found near the south pole. They swim in troops, and fight for their wives. 3. The vitulina, or sea-calf, has a smooth head, without external ears. They inhabit the European ocean. They generally sleep upon stones above the water, and are easily killed by a stroke above the nose.

PHOCEA, a city of Œolis, on the west coast of the lesser Asia, anciently so called.

PHOENICOPTERUS, or **FLAMINGO**, in ornithology, a genus of birds belonging to the order of grallæ. The beak is naked, teetted, and bent as if it were broken; the nostrils are linear; and the feet are palmated, and four-toed. There is but one species, a native of Africa and America.

PHOENIX, in astronomy. See **ASTRONOMY**, p. 487.

PHOENIX, the **GREAT PALM**, or **DATE-TREE**, in botany, a genus of plants, the characters of which are not yet perfectly ascertained: the male and female flowers are on distinct plants, or on the same spadix.

PHOLAS, a genus of insects belonging to the order of vermes testacea. The shell is double-valved and divaricated; the cardo is turned backwards, and connected by a cartilage. There are six species, distinguished by the figure of their shells.

PHONICS, the doctrine or science of sounds, otherwise called acoustics. See **PNEUMATICS**.

PHOSPHORUS. See **CHEMISTRY**, p. 123.

PHRENES,

PHRENES, in anatomy. See **ANATOMY**, p. 213.

PHRENSY, in medicine, an inflammation of the membranes of the brain, attended with an acute fever and delirium. See **MEDICINE**, p. 88.

PHRYGIA, the Greater and Lesser, two provinces anciently of Asia Minor; having the Hellespont on the north.

PHTHIRIASIS, in medicine, the pedicularis morbus, or lousy disease, is most incident to children, though adults are not wholly exempt from it.

PTHISIS, a species of consumption, arising from an ulcer of the lungs. See **MEDICINE**, p. 103.

PHYLLANTHUS, in botany, a genus of the monoecia triandra class. The calix both of the male and female consists of eight segments; neither of them have any corolla; the female has three bifid styli; the capsule has three cells, and contains one seed. There are six species, none of them natives of Britain.

PHYLLIS, in botany, a genus of the pentandria digynia class. The stigmata are rough; and the fruit is sparsely. There are two species none, of them natives of Britain.

PHYSALIS, in botany, a genus of the pentandria monogynia class. The corolla is rotated; the seeds are committent; and the berry has two cells, and is contained within an inflated calix. There are ten species, none of them natives of Britain.

PHYSETER, in zoology, a genus belonging to the order of Cete. It has teeth in the under jaw, and a fistula in the head or snout. There are four species, viz. 1. The catodon, with a fistula in the snout, and having no back-fin. 2. The macrocephalus has a fistula in the neck, and no back-fin. The spermaceti is extracted from the ventricles of its brain. 3. The microps, with along fin on the back, and the upper jaw much longer than the under one. 4. The turio, with a very high fin on the back, and the points of the teeth blunt. All the four species are inhabitants of the northern Ocean.

PHYSIC. See **MEDICINE**.

PHYSICAL, something relating to nature.

PHYSICIAN, a person who professes medicine, or the art of healing diseases.

PHYSICS, a denomination sometimes given to natural philosophy.

PHYSIOLOGY, properly denotes a discourse of nature, and natural bodies; or, it is that part of natural philosophy which treats of the various phenomena of nature in a scientific and speculative way.

Among physicians, the term physiology denotes the history of the human body and its several constituent parts, with their relations and functions.

PHYTEUMA, in botany, a genus of the pentandria monogynia class. The corolla is rotated, with linear laciniæ; the stigma is trifid; and the capsule has two or three cells. The species are six, only one of them, viz. the orbicularis, or horned rampion, a native of Britain.

PHYTOLACCA, in botany, a genus of the decandria decagynia class. It has no calix; the petals are five; and the berry has ten cells, and ten seeds. There are four species, none of them natives of Britain.

PHYTOLOGY, a discourse concerning the kinds and virtues of plants.

PIA MATER, in anatomy. See **ANATOMY**, p. 285.

PICA, in ornithology. See **CORVUS**.

PICA, in medicine, a depravation of appetite, which makes

the patient long for what is unfit for food, or incapable of nourishing, as chalk, ashes, coals, plaster, lime, &c.

PICAE, the name of a class of birds. See **NATURAL HISTORY**.

PICARDY, a province of France, bounded by the French Netherlands, and the Straights of Dover, on the north and east; by the Isle of France, on the south; and by Normandy, and the English channel, on the west.

PICKLE, a brine or liquor, commonly composed of salt, vinegar, &c. sometimes with the addition of spices; wherein meat, fruit, and other things are preserved and seasoned.

PICKERY, in Scots law, petty theft, or stealing things of small value.

PICKERING, a flying war or skirmish made by soldiers detached from two armies for pillage, or before a main battle begins.

PICRIS, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is naked; the calix is caliculated; the pappus is feathery; and the seeds are furrowed transversely. There are four species, two of them natives of Britain, viz. the echioides, or ox's tongue; and the hieracioides, or yellow fuccory.

PICTS WALT, in antiquity, a wall begun by the emperor Adrian, on the northern bounds of England, to prevent the incursions of the Picts and Scots. It was first made only of turf, strengthened with pallisades, till the emperor Severus coming in person into Britain built it with solid stone. This wall, part of which still remains, begun at the entrance of Solway-frith in Cumberland, and running N. E. extended to the German ocean.

PICTURE, a piece of painting, or a subject represented in colours, on wood, canvas, paper, or the like.

PICUS, the **WOOD-PECKER**, in ornithology, a genus belonging to the order of picæ. The beak is straight, and consists of many fides, and like a wedge at the point; the nostrils are covered with bristly feathers; the tongue is round like a worm, very long, sharp at the point, which is beset with bristles bent backwards. There are 21 species, distinguished by their colour.

PIECE, in heraldry, denotes an ordinary or charge. See **CHARGE**.

PIEDMONT, a principality of Italy, so called from its lying at the foot of the Alps. It is bounded by Savoy, from which it is separated by the Alps, on the north; by the duchies of Milan and Montserrat, on the east; by the territories of Genoa, and the county of Nice, on the south; and by France, on the west; being about 100 miles long, and 70 broad.

PIER, in building, denotes a mass of stone, &c. opposed by way of fortrefs against the force of the sea, or a great river, for the security of ships that lie at harbour in any haven.

PIETISTS, a religious sect sprung up among the protestants of Germany, seeming to be a kind of mean between the quakers of England, and the quietists of the Romish church.

PIG, in zoology. See **SUS**.

Guinea-Pig. See **MUS**.

Pig of lead the eighth part of a fother, amounting to two hundred and fifty pounds weight.

PIGEON, in ornithology. See **COLUMBA**.

PIGMENTS, preparations used by painters, dyers, &c. to impart

Impert colours to bodies, or to imitate particular colours.

FIGUS, in ichthyology. See **CYPRINUS**.

PIKE, in ichthyology. See **LUCIUS**.

PILASTER, in architecture. See **ARCHITECTURE**, p.

52.

PILCHARD, in ichthyology. See **CLUPEA**.

PILE, in heraldry, an ordinary in form of a wedge, contracting from the chief, and terminating in a point towards the bottom of the shield. See **PLATE CXXXIV.** fig. 16.

The pile, like other ordinaries, is borne inverted, in grailed, &c. and issues indifferently from any point of the verge of an escutcheon.

PILES, in medicine. See **MEDICINE**, p. 143.

PILGRIMAGE, a kind of religious discipline, which consists in taking a journey to some holy place, in order to adore the relics of some deceased saint. Pilgrimages began to be made about the middle ages of the church; but they were most in vogue after the end of the eleventh century, when every one was for visiting places of devotion, not excepting kings and princes themselves; and even bishops made no difficulty of being absent from their churches on the same account. The places most visited were Jerusalem, Rome, Compostella, and Tours; but the greatest numbers now resort to Loretto, in order to visit the chamber of the blessed virgin, in which she was born, and brought up her son Jesus, till he was twelve years of age.

PILL, in pharmacy, a form of medicine resembling a little ball, to be swallowed whole, invented in favour of such as cannot take bitter and ill-tasted medicinal draughts, as also to keep in readiness for occasional use without decaying.

PILLAR, in architecture, a kind of irregular column, round and insulated, but deviating from the proportions of a just column. See **ARCHITECTURE**.

PILLORY, was anciently a post erected in a cross road, by the lord of the manor, with his arms upon it, as a mark of his signory, and sometimes with a collar to fix criminals to.

PILOT, a person employed to cond. & ships over bars and sands, or through intricate channels, into a road or harbour.

PIMENTO, in botany. See **MYRTUS**, of which it is a species.

The fruits are gathered when green, and are exposed to the sun for many days on cloths, frequently shaking and turning them, till thoroughly dry; they take great care they are not wetted by the morning and evening dews; and when thus dried, are sent over to us.

Pimento abounds with a fragrant essential oil, which is separated, in great quantity, in distillation, and is so heavy that it sinks in water. This spice is much used in our foods, and sometimes in medicine: it is, indeed, a very good aromatic, and so well imitates the mixed flavour of all the rest, that it has long been a common practice to make the aqua mirabilis, which was ordered to be distilled from all the spices, of this ingredient alone; and the taste of the water thus made, when carefully done, is so near the genuine, that a very nice palate can only distinguish it.

PIMP NELLA, in botany, a plant of the pentandria digynia class. The fruit is oblong; and the corolla is sub-

radiated. There are four species, two of them natives of Britain, viz. the major, or great burnet saxifrage; and the saxifraga, or small burnet saxifrage.

PIN, in commerce, a little necessary implement made of brass-wire, used chiefly by the women in adjusting their drels.

The perfection of pins consists in the stiffness of the wire and its whiteness, in the heads being well turned, and in the fineness of the points. The London pointing and whitening are in most repute; because our pin-makers, in pointing, use two steel-mills, the first of which forms the point, and the latter takes of all irregularities, and renders it smooth, and as it were polished; and in whitening, they use block-tin granulated; whereas in other countries they are said to use a mixture of tin, lead, and quick-silver.

PINDARIC, in poetry, an ode formed in imitation of the manner of Pindar.

PINE, in botany. See **PINUS**.

PINE-APPLE. See **BROMELIA**.

PINEAL GLAND, in anatomy. See **ANATOMY**, p. 286.

PINGUICULA, in botany, a genus of the diandria monogynia class. The corolla is ringent; the calix is bilabiate; and the capsule has but one cell. There are four species, two of them natives of Britain, viz. the vulgaris, or butter-wort; and the lusitanica, or Cornwall butter-wort.

PINION, in mechanics, an arbor, or spindle, in the body whereof are several notches, which catch the teeth of a wheel that serves to turn it round: or it is a lesser wheel which plays in the teeth of a larger.

PINK, a vessel used at sea, masted and rigged like other ships, only that this is built with a round stern; the bends and ribs compassing so as that her ribs bulge out very much.

PINK, in botany. See **DIANTHUS**.

PINNACE, a small vessel used at sea, with a square stern, having sails and oars, and carrying three masts, chiefly used as a scout for intelligence, and for landing of men, &c.

PINNACLE, in architecture, the top or roof of an house, terminating in a point.

PINNATED LEAVES, in botany. See **BOTANY**, p. 64c.

PINUS, in botany, a genus of the monœcia monadelphica class. The calix of the male consists of four leaves; it has no corolla; the stamina are numerous, with naked antheræ. The calix of the female is a strobilus, containing two flowers; it has one pistillum; and the nut is embraced by a membranaceous wing. There are 12 species, three of them natives of Britain, viz. the sylvestris, or Scotch fir; the picea, or yellow-leaved fir; and the abies, or common fir.

PIONEER, in the art of war, a labourer employed in an army to smooth the roads, pass the artillery along, and dig lines and trenches, mines, and other works.

PIPE, in law, is a roll in the exchequer, called also the great roll. See the next article.

PIPE-OFFICE, is an office, wherein a person, called the clerk of the pipe, makes out leases of crown-lands, by warrant from the lord-treasurer, or commissioners of the treasury, or chancellor of the exchequer.

PIPER, **PEPPER**, in botany, a genus of the diandria trigynia class. It has neither calix nor corolla; the berry

contains but one feed. There are 20 species, all natives of warm countries.

PIPER, in ichthyology. See TRIGLA.

PIRACY, in Scots law. See LAW, Tit. xxxiii.

PIRATE, a person, or vessel, that robs on the high seas, without permission or authority of any prince or state.

PISA, a city of Italy, in the duchy of Tuscany, situated on the river Arno, four miles east of the sea, and ten miles north of Leghorn.

PISCARY, in our ancient statutes, the liberty of fishing in another man's waters.

PISCES, in astronomy, the twelfth sign or constellation of the zodiac. See ASTRONOMY, p. 487.

PISCINA, in antiquity, a large basin in a public place or square, where the Roman youth learned to swim, and which was surrounded with a high wall, to prevent casting of filth into it.

PISSAPHALTUM, EARTH PITCH, a fluid, opaque, mineral body, of a thick consistence, of a strong smell, readily inflammable, but leaving a residuum of greyish ashes after burning. It arises out of the cracks of rocks, in several places in the island of Sumatra, and in some other parts of the East-Indies, and is much esteemed there, in paralytic disorders.

PISSELAUM INDICUM, BARBADOES TAR, a mineral fluid, of the nature of the thicker bitumens, and of all others the most approaching in appearance, colour, and consistence, to the true pissaphaltum, though differing from it in other respects. It is very frequent in many parts of America, where it is found trickling down the sides of mountains in large quantities, and sometimes floating on the surface of the waters. It has been greatly recommended internally in coughs and other disorders of the breast and lungs.

PISTACIA, in botany, a genus of the dioecia pentandria class. The calyx of the amentum in the male consists of five segments; it has no corolla: The calyx of the female consists of three segments; it has no corolla; there are three styli; and the drupa contains one feed. There are five species, all natives of warm climates.

Pistachia-nuts abound with a sweet and well-tasted oil, which they will yield in great abundance, on being pressed after bruising them: they are reckoned wholesome and nutritive, and are very proper to be prescribed by way of restoratives, eaten in a moderate quantity, and to people emaciated with long illnesses.

PISTIL, among botanists. See BOTANY, p. 637.

PISTOL, the smallest piece of fire-arms, born at the saddle bow, on the girdle, and in the pocket.

PISTOLE, a gold-coin, struck in Spain, and in several parts of Italy, Switzerland, &c.

The pistole has its augmentations and diminutions, which are quadruple pistoles, double pistoles, and half pistoles.

PISTON, in pump-work, is a short cylinder of metal, or other solid substance, fitted exactly to the cavity of the barrel or body of the pump. See HYDROSTATICS.

PISUM, in botany, a genus of the diadelphia decandria class. The stylus is triangular, carinated and downy above; and the two upper laciniae of the calix are shorter than the rest. The species are four, only one of them, viz. the marimum, or pea-pease, a native of Britain.

Peas are nutritive, and accordingly used for food; but

rarely for any medicinal purposes, except to keep issues open; for which purpose they are rubbed with basilicon, or linimentum Arcae.

PITCH, a tenaceous oily substance, drawn chiefly from pines and firs, and used in shipping, medicine, and various other arts: or it is more properly tar, inspissated by boiling it over a slow fire.

The method of procuring the tar, is by cleaving the trees into small billets, which are laid in a furnace that has two apertures, through one of which the fire is put, and through the other the pitch is gathered, which, oozing from the wood, runs along the bottom of the furnace into places made to receive it. When the smoke, which is here very thick, gives it blackness, this is called tar; which, on being boiled, to consume more of its moisture, becomes pitch.

There is another method of drawing pitch, used in the Levant: a pit is dug in the ground, two ells in diameter at the top, but contracting as it grows deeper; this is filled with branches of pine, cloven into shivers; the wood at the top of the pit is then set on fire, and burning downwards, the tar runs from it out of a hole made in the bottom; and this is boiled, as above, to give it the consistence of pitch.

PITH, in vegetation, the soft spongy substance contained in the central parts of plants and trees. See AGRICULTURE, Part I.

PITUITARY GLAND, in anatomy. See ANATOMY, p. 286.

PLACE, in war, a general name for all kinds of fortresses where a party may defend themselves.

COMMON PLACE. See COMMON PLACE.

PLACENTA, in anatomy and midwifery, a soft roundish mass found in the womb of pregnant women; which, from its resemblance to the liver, was called by the ancients *hepar uterinum*, the uterine liver. See MIDWIFERY, p. 208.

PLACENTIA, a city of Spain, in the province of Estremadura: W. long. 69°, N. lat. 39° 45'.

PLAGIARY, in philology, the purloining another person's works, and putting them off for a man's own. Among the Romans, plagiarus was properly a person who bought, sold, or retained a freeman for a slave; and was so called, because by the Flavian law such persons were condemned, ad plagas, to be whipped.

PLAGIURI, among ichthyologists, a class of fishes comprehending all those which have the tails not perpendicular, but placed in an horizontal direction.

PLAGUE, PESTILENCE, or PESTILENTIAL FEVER. See MEDICINE, p. 71.

PLAISE, the English name of a species of the pleuronsctes. See PLEURONECTES.

PLAN, in general, denotes the representation of something drawn on a plane: such are maps, charts, ichnographies, &c.

The term plan, however, is particularly used for a draught of a building, such as it appears, or is intended to appear, on the ground; shewing the extent, division, and distribution of its area, or ground-plot, into apartments, rooms, passages, &c.

PLANE, in geometry, denotes a plain surface, or one that lies evenly between its bounding lines: and as a right line is the shortest extension from one point to another, so a plain

plain surface is the shortest extension from one line to another.

PLANE, in joinery, an edged tool, or instrument for parting and shaving of wood smooth.

It consists of a piece of wood, very smooth at bottom, as a stock or shaft; in the middle of which is an aperture, through which a steel edge, or chissel, placed obliquely, passes; which being very sharp, takes off the inequalities of the wood it is slid along.

PLANE-TREE, in botany. See **PLATANUS**.

PLANET, a celestial body, revolving round the sun as a centre, and continually changing its position, with respect to the fixed stars; whence the name *planet*, which is a Greek word, signifying *wanderer*. See **ASTRONOMY**.

PLANETARIUM, the same with orrery. See **ASTRONOMY**, p. 495.

PLANIMETRY, that part of geometry which considers lines and plain figures, without considering their height or depth. See **GEOMETRY**.

PLANISPHERE, signifies a projection of the sphere, and its various circles on a plane; in which sense maps, wherein are exhibited the meridians, and other circles of the sphere, are planispheres.

PLANT, is defined to be an organical body, destitute of sense and spontaneous motion, adhering to another body in such a manner as to draw from it its nourishment, and having power of propagating itself by seeds. See **AGRICULTURE** and **BOTANY**.

Sensitive PLANT. See **MIMOSA**.

PLANTA, in anatomy, the foot. See **ANATOMY**, p. 185.

PLANTAGO, in botany, a genus of the tetrandria monogynia class. The calix and corolla has each four segments; the stamina are very long; and the capsule is bilocular. There are 21 species, eight of them natives of Britain.

The root, leaves, and seeds of plantain, are reckoned cooling and astringent. It is likewise accounted a great healer of fresh wounds.

Water PLANTAIN. See **RANUNCULUS**.

PLANTARIS, in anatomy. See **ANATOMY**, p. 210.

PLANTATION, in the West-Indies, denotes a spot of ground which a planter or person arrived in a new colony, pitches on to cultivate for his own use, or is assigned for that purpose. However, the term plantation is often used in a synonymous sense with colony.

PLASTER, in pharmacy, is defined to be an external application, of a harder consistence than our ointments; these are to be spread according to the different circumstances of the wound, place, or patient, either upon linen or leather.

PLASTER, among builders, &c. The plaster of Paris is a preparation of several species of gypsums, dug near Mont Maitre, a village in the neighbourhood of Paris; whence the name.

The best sort is hard, white, shining, and marbly; known by the names of plaster-stone, or parget of Mount Maitre. It will neither give fire with steel, nor ferment with aqua fortis; but very freely and readily calcines in the fire, into a very fine plaster; the use of which in building, and casting statues, is well known.

PLASTIC, denotes a thing endued with a formative power, or a faculty of forming or fashioning a mass of matter, after the likeness of a living being; such a virtue as some

of the ancient Epicureans, and perhaps the Peripatetics too, imagined to reside in the earth, or at least to have anciently resided therein, by means whereof, and without any extraordinary intervention of a creator, it put forth plants, &c. Some of them seem to be of opinion, that animals, and even man himself, was the effect of this plastic power.

PLASTIC ART, a branch of sculpture, being the art of forming figures of men, birds, beasts, fishes, &c. in plaster, clay, fluc, or the like.

PLATA, a small island in the Pacific ocean, near the coast of Peru, situated W. long. 81°, S. lat. 1°. It is also the name of a city of Peru, capital of the province of La Plata, situated in W. long. 66° 30', S. lat. 22° 30'; and also the name of a great river of Peru, which rising in the province of La Plata, and running south-east till it joins the river Paragua, discharges itself into the Atlantic ocean, below the city of Buenos Ayres.

PLATALEA, or spoon-bill, in ornithology, a genus belonging to the order of grallæ. The beak is plain, and dilates toward the point into an orbicular form; the feet have three toes, and are half palmated. There are three species, distinguished by their colour.

PLATANUS, the **PLANE-TREE**, in botany, a genus of the monocæia polyandria class. The calix both of the male and female is a roundish amentum; the male has no corolla; the corolla of the female consists of many petals; the stigma is bent backward; and the seeds are round. The species are two, none of them natives of Britain.

PLATEAND, in gardening, a border or bed of flowers along a wall, or the side of a parterre frequently edged with box, &c.

PLATBAND of a door or window is used for the lintel, where that is made square or not much arched.

PLATFORM, in the military art, an elevation of earth, on which cannon is placed, to fire on the enemy; such are the mounds in the middle of curtains.

PLATFORM, in architecture, is a row of beams, which support the timber-work of a roof, and lie on the top of the wall, where the entablature ought to be raised.

PLATONIC, something that relates to Plato, his school-philosophy, opinions, or the like.

PLATONIC YEAR, or the **GREAT YEAR**, is a period of time determined by the revolution of the equinoxes. See **ASTRONOMY**, p. 562.

PLATOON, in the military art, a small square body of forty or fifty men, drawn out of a battalion of foot, and placed between the squadrons of horse, to sustain them.

PLATYSMA MYOIDES, in anatomy. See **ANATOMY**, p. 195.

PLEA, in law, is what either party alleges for himself in court, in a cause there depending; and in a more restrained sense, it is the defendant's answer to the plaintiff's declaration.

Court of Common PLEAS. See **COMMON-PLEAS**.

PLEASURE and pain, says Mr Locke, are simple ideas, which we receive both from sensation and reflection; there being thoughts of the mind, as well as sensations, accompanied with pleasure or pain. See **METAPHYSICS**.

PLEBEIAN, any person of the rank of the common people. It is chiefly used in speaking of the ancient Romans, who were divided into senators, knights, and plebeians.

PLEDGE,

PLEDGE, in Scots law. See **LAW**, Tit. xx. 13.

PLEDGET, **BOLESTER**, or **COMPRESS**, in surgery, a kind of flat tent, laid over a wound, to imbibed the superfluous humours, and keep it clean.

PLEIADES, in astronomy, an assemblage of stars in the neck of the constellation taurus. See **ASTRONOMY**, p. 487.

PLENARY, something complete or full.

PLENIPO TENTIARY, a person vested with full power to do any thing. See **EMBASSADOR**.

PLENTITUDE, the quality of a thing that is full, or that fills another. In medicine, it chiefly denotes a redundancy of blood and humours.

PLENUM, in physics, denotes, according to the Cartesians, that state of things, wherein every part of space is supposed to be full of matter; in opposition to a vacuum.

PLEONASM, a figure in rhetoric, whereby we use words seemingly superfluous, in order to express a thought with the greater energy: such as, I saw it with my own eyes, &c.

PLETHORA, in medicine, a greater redundancy of laudable blood and humours than is capable of undergoing those changes which must necessarily happen for the purposes of life without inducing diseases.

PLEURA, in anatomy. See **ANATOMY**, p. 278.

PLEURISY, in medicine. See **MEDICINE**, p. 89.

PLEURONECTES, in ichthyology, a genus belonging to the order of thoracici. Both eyes are on the same side of the head; there are from four to seven rays in the gill-membrane; the body is compressed, the one side resembling the back and the other the belly. There are 17 species.

PLEXUS, among anatomists, a bundle of small vessels interwoven in the form of net-work.

PLIMOUTH, or **PLYMOUTH**, a port-town of Devonshire, and a station for the building and laying up of ships of war belonging to the royal navy: W. long. 4° 27', N. lat. 50° 26'. It sends two members to parliament.

PLIMTON, a borough town of Devonshire, situated near the English Channel, thirty-six miles south-west of Exeter. It sends two members to parliament.

PLINIA, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals, and the calix of five segments; the berry is furrowed, and contains one seed. There is but one species, a native of America.

PLINTH, in architecture, a flat square member, in the form of a brick.

POLOSKOW, the capital of a palatinate of the same name, in Poland fifty miles north-west of Warsaw.

PLOT, in dramatic poetry, is sometimes used for the fable of a tragedy or comedy, but more particularly the knot or intrigue, which makes the embarrass of any piece.

PLOT, in surveying, the plan or draught of any field, farm, or manor surveyed with an instrument, and laid down in the proper figure and dimensions.

PLOTTING, among surveyors, is the art of laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, &c. and a chain. See **GEOMETRY**.

POLOVER, in ornithology. See **CHARADRIUS**.

PLOUGH, in agriculture, a machine for turning up the soil, contrived to save the time, labour, and expence, that without this instrument must have been employed in dig-

ging land, to prepare it for the sowing of all kinds of grain. See **AGRICULTURE**, p. 54.

PLOUGHMAN, the person who guides the plough in the operation of tilling.

PLOUGHING, in agriculture, turning up the earth with a plough. See **AGRICULTURE**, p. 57.

PLUKNETIA, in botany, a genus of the monœcia monodelphia class. Neither the male nor the female have any calix; the corolla of each has four petals; the male has four glandular bearded nectaria; the stylus is filiform the stigma is peltate; and the capsule has four cells, containing one seed. There is but one species, a native of India.

PLUM-TREE, in botany. See **PRUNUS**.

PLUMAGE, the feathers which serve birds for a covering.

PLUMB-LINE, among artificers, denotes a perpendicular to the horizon; so called, as being commonly erected by means of a plummet.

PLUMBAGO, in botany, a genus of the pentandria monogynia class. The corolla is bell-shaped; the stamina are inserted into scales at the base of the corolla; the stigma is quinquefid; and there is but one oblong truncated seed. The species are four, none of them natives of Britain.

PLUMBERY, the art of casting and working lead, and using it in buildings, &c.

As this metal melts very easily, it is easy to cast it into figures of any kind, by running it into moulds of brass, clay, plaster, &c. But the chief article in plumbery is sheets and pipes of lead: and as these make the basis of the plumber's work, we shall here give the process of making them. In casting sheet-lead, a table or mould is made use of, which consists of large pieces of wood well jointed, and bound with bars of iron at the ends, on the sides of which runs a frame consisting of a ledge, or border of wood, two or three inches thick, and two or three inches high from the mould, called the sharps; the ordinary width of the mould, within these sharps, is from three to four feet; and its length is sixteen, seventeen, or eighteen feet. This should be something longer than the sheets are intended to be, in order that the end where the metal runs off from the mould may be cut off, because it is commonly thin or uneven, or ragged at the end. It must stand very even or level in breadth, and something falling from the end in which the metal is poured in, viz. about an inch, or an inch and a half, in the length of sixteen or seventeen inches. At the upper end of the mould stands the pan, which is a concave triangular prism, composed of two planks nailed together at right angles, and two triangular pieces fitted in between them at the ends. The length of this pan is the whole breadth of the mould in which the sheets are cast: it stands with its bottom, which is a sharp edge, on a form at the end of the mould, leaning with one side against it; and on the opposite side is a handle to lift it up by, to pour out the melted lead; and on that side of the pan next the mould are two iron hooks to take hold of the mould, and prevent the pan from slipping, while the melted lead is pouring out of it into the mould. This pan is lined on the inside with moistened sand, to prevent it from being fired by the hot metal. The mould is also spread over, about two thirds of an inch thick, with sand sifted and moist-

ened

ened, which is rendered perfectly level by moving over it a piece of wood called a strike, by tramping upon it with the feet, and smoothing it over with a smoothing plane, which is a thick plate of polished brass, about nine inches square, turned up on all the four edges, and with a handle fitted on to the upper or concave side. The sand being thus smoothed, it is fit for casting sheets of lead: but if they would cast a cistern, they measure out the bigness of the four sides; and having taken the dimensions of the front, or fore-part, make mouldings by pressing long slips of wood, which contain the same mouldings, into the level sand, and form the figures of birds, beasts, &c. by pressing in the same manner leaden figures upon it, and then taking them off, and at the same time smoothing the surface where any of the sand is raised up, by making these impressions upon it. The rest of the operation is the same in casting either cisterns or plain sheets of lead: but before we proceed to mention the manner in which that is performed, it will be necessary to give a more particular description of the strike. The strike then is a piece of board about five inches broad, and something longer than the breadth of the mould on the inside; and at each end is cut a notch, about two inches deep, so that when it is used, it rides upon the sharps with those notches. Before they begin to cast, the strike is made ready by tacking on two pieces of an old hat on the notches, or by slipping a case of leather over each end, in order to raise the under side about one eighth of an inch, or something more, above the sand, according as they would have the sheet to be in thickness; then they tallow the under edge of the strike, and lay it across the mould. The lead being melted, it is laddled into the pan, in which, when there is a sufficient quantity for the present purpose, the scum of the metal is swept off with a piece of board to the edge of the pan, letting it settle on the sand, which is by this means prevented from falling into the mould at the pouring out of the metal. When the lead is cool enough, which is known by its beginning to stand with a shell or wall on the sand round the pan, two men take the pan by the handle, or else one of them lift it up by a bar and chain fixed to a beam in the ceiling, and pour it into the mould, while another man stands ready with the strike, and, as soon as they have done pouring in the metal, puts on the mould, sweeps the lead forward, and draws the overplus into a trough prepared to receive it. The sheets being thus cast, nothing remains but to planish the edges in order to render them smooth and straight; but if it be a cistern, it is bent into four sides, so that the two ends may join the back, where they are soldered together, after which the bottom is soldered up.

The method of casting thin sheets of lead. Instead of sand, they cover the mould with a piece of woollen stuff nailed down at the two ends to keep it tight, and over this lay a very fine linen cloth. In this process great regard is had to the just degree of heat, so as that the lead may run well, and yet not burn the linen. This they judge of by a piece of paper; for it takes fire in the liquid lead if it is too hot, and if it be not shrunk and s'ched a little, it is not hot enough. They have here a strike different from that described above: it is a wooden case, only closed on three sides: it is pretty high behind; but the two sides, like two acute angles, still diminish to the tip from the place where they are joined to the third or middle piece, where they are of the same height therewith, viz. seven or eight

inches high, the width of the middle makes that of the strike, which again makes that of the sheet to the cast. This strike is placed at the top of the mould, which in that part is first covered with a pasteboard that serves as a bottom to the case, and prevents the linen from being burnt while the lead is pouring in. The strike is now filled with lead, according to the quantity to be used; which done, two men, one at each side, draw the strike down the mould with a velocity greater or less, as the sheet is to be more or less thick.

The method of casting pipes without soldering. To make these pipes, they have a kind of little mill, with arms or levers to turn it withal. The moulds are of brass, and consist of two pieces, which open and shut by means of hooks and hinges, their inward caliber, or diameter, being according to the size of the pipe to be made, and their length is usually two feet and a half. In the middle is placed a core, or round piece of brass or iron, somewhat longer than the mould, and of the thickness of the inward diameter of the pipe. This core is passed through two copper-rundles, one at each end of the mould, which they serve to close; and to these is joined a little copper-tube about two inches long, and of the thickness the leaden pipe is intended to be of. By means of these tubes the core is retained in the middle of the cavity of the mould. The core being in the mould, with the rundles at its two ends, and the lead melted in the furnace, they take it up in a ladle and pour it into the mould by a little aperture at one end, made in the form of a funnel. When the mould is full they pass a hook into the end of the core, and turning the mill, draw it out; and then opening the mould, take out the pipe. If they desire to have the pipe lengthened, they put one end of it in the lower end of the mould, and pass the end of the core into it; then shut the mould again, and apply its rundle and tube as before, the pipe just cast serving for rundle, &c. at the other end. Things being thus replaced, they pour in fresh metal, and repeat the operation till they have got a pipe of the length required.

For making pipes of sheet-lead, the plumbers have wooden cylinders of the length and thickness required; and on these they form their pipes by wrapping the sheet around them, and soldering up the edges all along them.

PLUMBUM, LEAD See CHEMISTRY, p. 84.

PLUMS, in botany See AGRICULTURE, p. 41.

PLUMMET, PLUMB RULE, or PLUMB LINE, an instrument used by carpenters, masons, &c. in order to judge whether walls, &c. be upright planes, horizontal, or the like. It is thus called from a piece of lead, fastened to the end of a cord, which usually constitutes this instrument. Sometimes the string descends along a wooden ruler, &c. raised perpendicularly on another; in which case it becomes a level.

PLUMMING, among miners, is the method of using a mine-dial, in order to know the exact place of the work where to sink down an air-shaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

It is performed in this manner: A skilful person, with an assistant, and with pen, ink and paper, and a long line, and a sun-dial, after his guess of the place above ground, descends into the adit or work, and there fastens one end of the line to some fixed thing in it; then the incited needle

is let to rest, and the exact point where it rests is marked with a pen: he then goes on farther in the line still fastened, and at the next flexure of the adit he makes a mark on the line by a knot or otherwise; and then letting down the dial again, he there likewise notes down that point at which the needle stands in this second position. In this manner he proceeds, from turning to turning, marking down the points, and marking the line, till he comes to the intended place: this done, he ascends, and begins to work on the surface of the earth what he did in the adit, bringing the first knot in the line to such a place where the mark of the place of the needle will again answer its pointing, and continues this till he come to the desired place above ground, which is certain to be perpendicularly over the part of the mine into which the air-shaft is to be sunk.

PLUMOSE, something formed in the manner of a feather,

with a stem and fibres issuing from it on each side; such are the antennæ of certain moths, butterflies, &c.

PLURAL, in grammar, an epithet applied to that number of nouns and verbs which is used when we speak of more than one thing. See GRAMMAR.

PLURALITY, a discrete quantity, consisting of two or a greater number of the same kind; thus we say a plurality of gods, &c.

PLUS, in algebra, a character marked thus +, used for the sign of addition.

PLUSH, in commerce, &c. a kind of stuff having a sort of velvet knap, or shag, on one side, composed regularly of a woof of a single woollen thread, and a double warp; the one woof, of two threads twisted; the other goats or camels hair; though there are some plushes entirely of worsted, and others composed wholly of hair.

PLUVIALIS, in zoology. See CHADRIS.

P N E U M A T I C S.

THIS science treats of the nature, weight, and pressure of the air, and the effects arising from it.

The air is that thin transparent fluid body in which we live and breathe. It encompasses the whole earth to a considerable height; and, together with the clouds and vapours that float in it, is called the atmosphere. The air is justly reckoned among the number of fluids, because it has all the properties by which a fluid is distinguished. (See HYDROSTATICS.) For it yields to the least force impressed, its parts are easily moved among one another, it presses according to its perpendicular height, and its pressure is every way equal.

That the air is a fluid, consisting of such particles as have no cohesion betwixt them, but easily glide over one another, and yield to the slightest impression, appears from that ease and freedom with which animals breathe in it, and move through it without any difficulty or sensible resistance.

But it differs from all other fluids in the three following particulars. It can be compressed into a less space than what it naturally possesseth, which no other fluid can. 2. It cannot be congealed or fixed, as other fluids may. 3. It is of a different density in every part, upward from the earth's surface, decreasing in its weight, bulk for bulk, the higher it rises; and therefore must also decrease in density. 4. It is of an elastic or springy nature, and the force of its spring is equal to its weight.

That air is a body, is evident from its excluding all other bodies out of the space it possesses; for, if a glass jar be plunged with its mouth downward into a vessel of water, there will but very little water get into the jar, because the air of which it is full keeps the water out.

As air is a body, it must needs have gravity or weight; and that it is weighty, is demonstrated by experiment. For, let the air be taken out of a vessel by means of the air-pump; then, having weighed the vessel, let in the air again; and upon weighing it, when re-filled with air, it will be found considerably heavier. Thus, a bottle that holds a wine quart, being emptied of air, and weighed, is found to be about 17 grains lighter than when the air is let into it again; which shews that a quart of air weighs 17 grains. But a quart of water weighs 14625 grains; this divided by

17, quotes 860 in round numbers; which shews, that water is 860 times as heavy as air near the surface of the earth.

As the air rises above the earth's surface, it grows rarer, and consequently lighter, bulk for bulk. For since it is of an elastic or springy nature, and its lowermost parts are pressed with the weight of all that is above them, it is plain that the air must be more dense or compact at the earth's surface, than at any height above it; and gradually rarer the higher up. For, the density of the air is always as the force that compresseth it: and therefore, the air towards the upper parts of the atmosphere being less pressed than that which is near the earth, it will expand itself, and thereby become thinner than at the surface of the earth.

Dr Cotes has demonstrated, that if altitudes in the air be taken in arithmetical proportion, the rarity of the air will be in geometrical proportion. For instance,

At the altitude of	miles above the surface of the earth, the air is	times thinner and lighter than at the earth's surface.	7

The weight or pressure of the air is exactly determined by the following experiment.

The TORICELLIAN EXPERIMENT.

Take a glass tube about three feet long, and open at one end: fill it with quicksilver; and putting your finger upon the open end, turn that end downward, and immerse it into a small vessel of quicksilver, without letting in any air: then take away your finger, and the quicksilver will remain suspended in the tube $29\frac{1}{2}$ inches above its surface in the vessel; sometimes more, and at other times less, as the weight of the air is varied by winds and other causes. That the quicksilver is kept up in the tube by the pressure of the atmosphere upon that in the basin, is evident; for, if the basin and tube be put under a glass, and the air be then taken out of the glass, all the quicksilver in the tube will fall down into the basin; and if the air be let in again, the quicksilver will rise to the same height as before. Therefore the air's pressure on the surface of the earth, is equal to the weight of $29\frac{1}{2}$ inches depth of quicksilver all over the earth's surface, at a mean rate.

A square column of quicksilver, $29\frac{1}{2}$ inches high, and one inch thick, weighs just 15 pounds, which is equal to the pressure of air upon every square inch of the earth's surface; and 144 times as much, or 2160 pounds, upon every square foot; because a square foot contains 144 square inches. At this rate, a middle-sized man, whose surface may be about 14 square feet, sustains a pressure of 30240 pounds, when the air is of a mean gravity: a pressure which would be insupportable, and even fatal to us, were it not equal one very part, and counterbalanced by the spring of the air within us, which is diffused through the whole body, and re-acts with an equal force against the outward pressure.

Now since the earth's surface contains (in round numbers) 200,000,000 square miles, and every square mile 27,878,400 square feet, there must be 5,575,680,000,000,000 square feet on the earth's surface; which multiplied by 2160 pounds (the pressure on each square foot) gives 12,043,468,800,000,000,000 pounds for the pressure or weight of the whole atmosphere.

When the end of a pipe is immersed in water, and the air is taken out of the pipe, the water will rise in it to the height of 33 feet above the surface of the water in which it is immersed; but will go no higher: for it is found, that a common pump will draw water no higher than 33 feet above the surface of the well: and unless the bucket goes within that distance from the well, the water will never get above it. Now, as it is the pressure of the atmosphere, on the surface of the water in the well, that causes the water to ascend in the pump, and follow the piston or bucket, when the air above it is lifted up: it is evident, that a column of water 33 feet high, is equal in weight to a column of quicksilver of the same diameter $29\frac{1}{2}$ inches high; and to as thick a column of air, reaching from the earth's surface to the top of the atmosphere. See HYDROSTATICS.

OF THE BAROMETER.

In serene calm weather, the air has weight enough to support a column of quicksilver 31 inches high; but in tempestuous stormy weather, not above 28 inches. The quicksilver, thus supported in a glass tube, is found to be a nice counterbalance to the weight or pressure of the air, and to shew its alterations at different times. And being now ge-

nerally used to denote the changes in the weight of the air, and of the weather consequent upon them, it is called the *barometer*, or *weather-glass*.

The mercury will stand at the same height either in an inclined barometer or in an erect one.

If the mercury at any time stands at the height of 30 inches in the barometer D, (Plate CXLV. fig. 6.) then by inclining this barometer into the position E, the perpendicular height of the mercury will not be altered; for it will still stand at the height of 30 inches: so that if the level AB is 30 inches from the surface FG, the mercury will stand at this level, either in the erect tube D, or in the inclined one E. Now here it is evident, that if NL is the height of the mercury when the tube is erect, and NM is the height of the mercury in the same tube or an equal one when it is inclined, there must be more mercury in the inclined tube than there is in the erect one. For we may consider NL as the side, and NM as the diagonal, of a right-angled parallelogram. But the diagonal of a right-angled parallelogram is longer than the side. Therefore, though either L or M are at the same perpendicular distance from FG, yet NM will be longer than NL. Since then the column of mercury is longer in the inclined tube than in the erect one, there will be more mercury in the inclined than in the erect one. The question therefore is, How the pressure of the atmosphere can support a greater quantity of matter in one situation of the tube than in the other. We cannot say, that though in the inclined tube there is a greater quantity of mercury than in the erect one, yet a part of this greater weight will be supported by the side of the tube as by an inclined plane. The true answer is, that the column of air which supports the mercury in the inclined tube, is greater than the column which supports it in the erect one. The height of the column of air is indeed the same in both cases; for in either case it is equal to the height of the atmosphere. But the base of the column of air, and consequently its weight, is greater when the tube is inclined than when it is erect. For the base of the column of air which supports the mercury in the tube, is equal to as much of the stagnant mercury's surface as the base of the tube covers. Now, if the diameters of the tubes D and E are equal; the base of the inclined tube E will cover a greater part of the surface FG than the erect tube D covers; or the base of the tube E will be greater than the base of the tube D. For the contents of the inclined tube are greater than those of the erect one, as has been shewn already. But the column of mercury in each of the tubes are cylinders of the same height. Therefore their bases are as their contents. Euc. b. XII. prop. 11. Since then the contents or the weights of mercury in each tube are as their bases, when their heights are equal; and the base of the column of air, which supports the mercury, and consequently the weight of this column, is proportional to the base of the tube; it follows, that the weight of the air will always be proportional to the weight of the mercury when it stands at a given height, whether the tube is inclined or erect.

Though we have here shewn, that the contents of the inclined tube are greater than those of the erect one; and consequently that their bases must be unequal, since their perpendicular heights are the same; yet it will not be improper to shew what we mean by the base of the inclined tube, or rather of the inclined column of mercury, and why this should be greater than the base of the erect one. Now by

the base of the inclined column we do not mean the bottom of the inclined tube, but the lowest horizontal section of it. Thus, if we consider the surface FG as a plane passing through the two tubes D and E, this plane will cut the tube D perpendicularly, and the tube E obliquely. But a perpendicular section of a cylinder is a circle, and an oblique section of it is an ellipse. Therefore the base of the erect column is circular, and the base of the inclined tube is elliptical. Now, by the supposition, the two tubes have equal diameters, and consequently the shorter axis of the elliptical base will be equal to the diameter of the circular one.

There is another sort of inclined barometer, such an one as ABR, (*ibid.* fig. 7.) which is erect for 28 inches from A to B, and then is inclined from B to C. The mercury will stand at the same height in this barometer, as if it had been a straight one AS: for the column of air pressing at the base A would be the same in either case: and though there is more mercury in the tube ABR than there would be in the tube ABS; yet, supposing the mercury to stand at the same level DC in either case, the pressure of the mercury downwards will in either case be the same. For, the pressure of fluids is as their base and perpendicular height: and here the base A is the same, and the perpendicular height is the same, whether the tube is erect all the way up as AS, or is inclined at the top as ABR.

The advantage which is proposed by these diagonal barometers, as they are called, is to make the variation of the mercury greater, and consequently more apparent, upon a given change in the weather. Thus suppose AB or 28 inches to be the least height of the mercury, and AD or 31 inches to be the greatest height of it: then the whole variation will be within the compass BD, or 3 inches. But if the barometer, instead of being erect at the top, is inclined into the position BC; then, as the mercury stands at the same perpendicular height in this diagonal barometer as in an erect one. AB will be the least height, and ABC will be the greatest height, since D and C are on the same level or at the same perpendicular distance from A. Now though BD, one side of the parallelogram, is but 3 inches long; yet BC may be 30 inches long, or more; and consequently since AB is the least height, and ABC is the greatest height, the variation of the mercury will be much greater than in an erect barometer; in particular, if BC is 30 inches long, the variation will be 30 inches instead of 3, or will be 10 times greater in the diagonal barometer than it would have been in an erect one.

The barometer stands at the same perpendicular height, whether the tube is large or small.

If the mercury stands at the same height either in the large tube C or in the small tube D, there must be more mercury in the large one than in the small one. But since the heights are equal, the quantities of mercury contained in these tubes will be as their bases. Now since the columns of air, by which the mercury is supported in these tubes, are as the respective bases of the tubes, the columns of air will be proportional to the weights in each tube, when the perpendicular heights are equal.

But though the heights of the mercury would be the same in small tubes as in large ones, if, as we must suppose in the proposition, the mercury moved equally free in both; yet in fact, upon any change of weather, the variation will be greater in a large tube than in a small one: because, in

a large tube, the weight of mercury is so great, that the motion of it will not be hindered by any attraction or repulsion of the glass upon it; whereas, in a small tube, where the weight of mercury is less, the action of the glass is considerable in proportion to that weight, and consequently the variations will be less upon a given change of the weather.

The barometer will commonly be low in rainy weather.

From what has been said already about the barometer, it appears, that the mercury will be low when the weight of the atmosphere is diminished; and such a diminution of the atmosphere will occasion rain. Therefore, since rain is occasioned by the same cause that makes the mercury fall, the barometer will commonly stand low in rainy weather.

The barometer is the lowest of all in violent storms of wind.

When the air moves horizontally with a great velocity, as it does in violent storms of wind, its weight, or rather its pressure downwards occasioned by its weight, will be diminished. For as any heavy body may have such a velocity given it, when it is thrown down horizontally, as may either carry it quite off from the earth's centre, or such a velocity as will make it move round the earth in a circle without either departing from the centre or approaching to it; so every degree of velocity given to the air will make it tend or press less towards the centre; and for this reason, as the mercury in the barometer will be less pressed, the height of it in the tube will be less in storms than it is any other time.

When a storm of wind is over, the mercury will rise very fast:

Because as the horizontal velocity of the air ceases, the pressure downwards will be suddenly restored, and consequently the mercury in the barometer will keep rising as this pressure is restored.

OF THE THERMOMETER.

The variations of different thermometers are seldom equal, upon equal variations of heat or cold.

A THERMOMETER is a well-known instrument for estimating different degrees of heat or cold. It consists of a tube or stem, with a hollow ball at one end of it. The cavity of the ball, and part of the tube, is filled with spirits of wine, or with linseed oil, or with mercury. The upper end of the tube is commonly sealed hermetically. But in sealing this end, the liquor in the thermometer is rarefied by heating it till it almost fills the tube; so that when it is sealed, and the liquor contracts again as it cools, there will be a vacuum left in the upper part of the tube. Any of these fluids will rarely fly by heat, and will contract again when they cool: and consequently in warm weather, the spirits, or the oil, or the mercury, whichever the thermometer is made of, will stand higher than in cold weather.

Thus far thermometers may be said to vary alike: they will either rise or sink from the same causes. But then, upon an equal increase of heat, they seldom vary equally, though they are made of the same liquor. One thermometer made with spirits of wine may vary upon an equal increase of heat much more than another that is made with the same sort of spirits: so that if one rises an inch, another may rise but $\frac{1}{2}$ or $\frac{1}{4}$ inch.

The variation of a thermometer is directly as the capacity of

of the ball, and inversely as the base of the stem. First, If the base of the stem or cylindrical tube is given, the variation, when the spirits are equally warmed, will be directly as the capacity of the ball. For when the spirits are equally warmed, and consequently are equally rarefied in the balls of two different thermometers, whatever proportion the bulk of the spirits in one ball bears to the bulk of the spirits in the other ball before they were rarefied, the same proportion these bulks will still bear to each other after they are rarefied. Thus, if one ball is double the other, and consequently the bulk of spirits in one is double the bulk of spirits in the other before they are warmed; then, upon being warmed equally, their densities will diminish equally. But if their densities diminish equally, their bulks will still have the same proportion to each other; or the bulk of spirits in one thermometer will still be double the bulk in the other. But if the bulks continue in the same proportion to each other, after they are swelled as they were before; the spirits must swell in proportion to their respective bulks, or the spirits in one must swell twice as much as in the other. But if the spirits swell in this proportion, and by swelling rise into equal tubes in each, they must rise twice as high in the tube of one of these thermometers as they do in the tube of the other. And so, in all other instances, the spirits, upon being equally warmed, will swell in proportion to their bulk, that is, in proportion to the capacity of the ball that contains them. But the heights, to which they rise in equal tubes, will be as the increase of their bulk. Therefore the heights to which they rise, or the variations in equal degrees of heat, will be as the capacity of the ball, when the tubes are equal. We have here supposed that the spirits in the balls of the thermometers are equally heated quite through. In sudden changes of heat and cold, it will be otherwise: for the spirits in a small ball will be sooner heated quite through than in a large one. And consequently, if the heat does not last long enough to warm the spirits in a large ball as much as they are warmed in a small one, the spirits will not be equally rarefied in both, and will not swell in proportion to their respective bulks; but those in the small ball will swell more in proportion than those in the large one. Secondly, If the balls are equal, the variations will be inversely as the bases of the stems. For if the balls are equal, then, upon being equally heated, the spirits contained in them will swell equally; and consequently equal quantities will rise into the stems. Now the spirits which rise into a cylindrical stem are a cylindrical column. But the heights of equal cylinders are inversely as their bases. Therefore, when the balls are equal, and equal cylinders of spirits rise into the stems, the heights to which they rise, or the variations, will be inversely as the bases of the stems.

An universal scale may be made, by which the variations of different thermometers may be compared with one another.

Let the ball of a thermometer be put into water when it is beginning to freeze, or, which is the same as to heat or cold, into snow when it is beginning to melt; and let the place where the fluid in the thermometer stands be marked. The place where the fluid stands in such a trial is the freezing point. Let the ball of the same thermometer be put into water just hot enough to let wax, that swims upon it, begin to coagulate. This again is another determinate degree of heat, and is to be marked upon the thermometer.

Divide the distance between these two points into 110 equal parts; and each of these parts we call a degree. Now a thermometer often sinks lower than the freezing point; because the cold is frequently more intense than what is just sufficient to make water freeze: for this reason, the scale must not begin from the freezing point. This point, therefore, should not be marked 0, nor should the point where melted wax begins to coagulate be marked 110. In this scale, which from the inventor is called Fahrenheit's scale, the freezing point is marked 32; and then the point, where melted wax begins to coagulate, being 110 degrees above it, must be marked 142. When the length of a degree is thus found in one part of the scale, 32 degrees of the same length are set off below the freezing point, and as many such degrees as we please are set off above the point where melted wax begins to coagulate. If the thermometer is made with spirits of wine, only 33 degrees need be set off or marked above 142: and then the scale will begin from 0; 32 degrees will be the freezing point; 142 will be the point where melted wax begins to coagulate; and $142 + 33 = 175$ degrees will be the highest point marked in the scale. The reason why no higher degree need be marked in a scale applied to a thermometer made with spirits, is, that at this degree of heat the spirits will boil, and consequently the thermometer would burst. But if the thermometer is made with mercury, the scale should contain at least 212 degrees from the bottom to the top, or 32 degrees below the freezing point, and 180 above it. The heat of boiling water, at the middle height of the mercury in the barometer, or in the middle weight of the atmosphere, will raise the mercury in the thermometer to 212 degrees, or 180 degrees above the freezing point. A thermometer made with mercury will not burst in such a degree of heat as this; for mercury requires a greater degree to make it boil.

In thermometers with such a scale, or, as they are called, in Fahrenheit's thermometers, the greatest degree of heat in the external parts of the human body is commonly about 96. Boerhaave imagined that air, if its heat exceeded 80 or 90 degrees at most, would be destructive to the life of animals. But in this he was mistaken. For in the year 1732 the thermometer in Pennsylvania was at the height of 96 or 97; and in the year 1734 the height of it at Petersburg was 98 degrees. The thermometer in our own climate is scarce ever higher than 78 degrees, and seldom lower than 18; so that we may reckon 48 degrees to be the middle temperature of our air.

The variations of different thermometers, though they are not equal, may be compared with one another by Fahrenheit's scale. For each degree upon different thermometers is proportional to their respective variations; and consequently, though in equal heats one may vary more than another, yet each will vary an equal number of degrees. Thus, if, upon any given increase of heat, one thermometer will vary twice as much as another, then the distance between the freezing point and the point where melted wax begins to coagulate will be twice as great, or 110 degrees will be twice as long, in one as in the other. Therefore each degree will be twice as long in the former thermometer as in the latter. But by the supposition, one of these thermometers in a given degree of heat will vary twice as much as the other does; and consequently, whatever heat raises the former one degree, will likewise raise the latter one degree.

If the ball of a thermometer is dipped into hot water, the fluid in the thermometer will sink a little before it begins to rise.

Not only fluids, such as spirits, oil, or mercury, but likewise glass, or iron, or almost any hard bodies, will expand when they are heated, and will contract again when they grow cold. Now, when the ball of a thermometer is dipped into hot water, the heat will be communicated to the glass of which the ball is made, before it is communicated to the fluid contained in the ball. By this means the ball will be expanded, and the capacity of it will be increased, so that some of the fluid will sink out of the item into it. But when the ball has been long enough in the water for the fluid within it to be heated, this fluid will be expanded: and then it will rise into the item, and will continue to rise as the heat increases.

OF SOUND.

Sound, in the body that produces it, is a trembling motion: this motion is communicated to the air, and the air conveys it to the ear.

WHEN any elastic body is struck, so as to produce a sound, the body, or some part of it, is made to vibrate. This is evident to sense in the strings of a violin or harpichord; for either the eye may see, or the hand may feel, the trembling of the strings, when by striking them they are made to sound. See MUSIC.

If a bell is struck by its clapper on the inside, the bell is made to vibrate. The base of the bell is a circle; but by striking any part of this circle on the inside, the part which is struck will fly out a little way, so that the diameter, which passes through this part of the circular base, will become longer than another diameter which crosses this at right angles. Therefore by the stroke the base will be changed into an ellipsis, whose longer axis will pass through the part against which the clapper struck. But the elasticity of the bell will restore the figure of the base, and will make the part which was forced out of its place return back. This part in returning will acquire velocity, in the same manner as an elastic string would in the same circumstances. And since it acquires velocity in returning to its place, it will not stop at that place, but will over-run it. Thus the circular figure of the base will be changed into an ellipsis again; only now the shorter axis will pass through the part that was first struck. If the bell was to be struck at first by a hammer on the outside, the part struck would move inwards; and such a motion would likewise change the base into an ellipsis: only in this case the shorter axis of the ellipsis would pass through that part where the blow was given. The elasticity of the bell will restore its figure; and as the part which was struck will acquire velocity in returning to its proper situation, the acquired velocity will not suffer it to rest there, but will carry it farther out from the opposite side; and the base will by this means be again changed into an ellipsis, having the longer axis at that part where the blow was first given. Thus we have seen, that where-ever the bell is struck, the parts of it will perform one vibration; the part, which is struck will yield to the blow; the elasticity of the bell will bring it back to its former situation; in returning, it will acquire velocity; and as far as the blow had driven it one way, so far the acquired velocity will car-

ry it the other. But since, after one vibration is thus performed, the figure of the base will be elliptical; the parts of the bell will vibrate a second time; and so on, in the same manner that an elastic string vibrates.

The same stroke which makes a bell vibrate makes it sound too; and as the vibrations decay, the sound grows weaker. Our senses may convince us that the parts of a bell are in a trembling or vibratory motion whilst the bell sounds: for if we lay our hand upon it, we may feel it jar; or if small straws or pieces of paper are thrown upon it, we may see that the jarring or trembling of the bell will put them in motion.

But the air must convey this vibratory motion to the ear: for otherwise, though the sounding body is made to vibrate, no sound will be heard. Thus if a bell is rung in the receiver of an air-pump, the sound will grow weaker as the air is exhausted; and, when all the air is drawn out of the receiver, no sound at all will be heard. When the air is admitted again into the receiver, the sound will at the first entrance of the air begin to be heard, and will grow louder as more air returns. If the bell was to be rung in like manner in a vessel where the air is condensed, the sound of it would be much louder than it is in common air. And accordingly, when divers are let down to any great depth of water, because the air in the diving-bell is much condensed, they seem to one another to speak much louder than usual.

The intensity of sound, at different distances from the sounding body, is inversely as the squares of the distances.

Sounds may differ from one another, both in respect of their tone, and in respect of their intensity or strength. In respect of their tone, they are distinguished into grave and acute; in respect of their intensity, they are distinguished into loud or strong, and low or weak. The tone of any sound depends upon the time that an impression continues, and is not altered by the distance of the ear from the sounding body. But the intensity or strength of any sound depends upon the force with which the particles of air, as they are condensed, strike the ear; and this force is found to be different at different distances, so that a sound which is very loud if we are near the body that produces it, would be weaker if we were farther from it, and our distance from it may be so great that we cannot hear it at all.

The proportion in which the intensity of sound decreases, as the distance of the ear from the sounding body increases, is this: If the different distances at which the ear is placed are to one another as 1, 2, 3, 4, 5; then the squares of those distances are 1, 4, 9, 16, 25; and the intensity of sound will be inversely as these squares, or as the reciprocals of these squares; that is, the strength of the sound will decrease in the same proportion with the fractions, $\frac{1}{1}, \frac{1}{4}, \frac{1}{9}, \frac{1}{16}, \frac{1}{25}$, which are the reciprocals of 1, 4, 9, 16, 25. This is what we mean when we say, that the intensity of sound is inversely as the squares of the distances, or that it decreases in the departure of the ear from the sounding body in the same proportion that the squares of the distances increase.

The intensity of sound decreases as the vibrations in the sounding body grow weaker.

If an elastic string was to stop all at once, the sound produced by it would cease immediately. But if the vibrations of

of the string decay gradually, the sound will likewise keep growing weaker, till it becomes too weak to be heard. The string performs all its vibrations from the first to the last in equal times, and consequently each pulse that the string produces is produced in an equal time, and upon that account each pulse from the first to the last will have the same thickness. But when the thickness of the pulse is given, the quantity of air, or number of particles, by which the ear is struck, will likewise be given; and the moment with which it is struck, or the intensity of the sound, will be as the velocity with which the particles move. Now the velocity of the string is successively communicated to the particles of air, as they are made to vibrate. Therefore, as the velocity of the string decays, the velocity of the particles, and consequently the intensity of the sound, will likewise decay.

The intensity of sound is increased by a speaking-trumpet.

When a man speaks without such a trumpet, the pulses, as they are produced, dilate themselves in all directions, or the motion is immediately communicated to the air all round him. But if he speaks in a trumpet, his voice, that is, the motion produced by his voice, is confined to the small portion of air contained in the trumpet. For this reason, as there are fewer particles to be moved than there are when the motion dilates itself immediately in all directions, the motion that is communicated will be greater, and consequently, when the voice comes out of the trumpet, its intensity or strength will be greater, than it would have been if it had been propagated in all directions at first.

Sound moves with the same velocity at all distances from the sounding body.

The sound of a cannon, or of a bell, moves at the rate of 1142 feet in a second at all distances from the gun or the bell. If it moves at this rate for the first mile, it would move just at the same rate for the second mile: so that a person who is within one mile of the cannon when it is discharged, will hear the report just as soon again as another who is at the distance of two miles. The velocity of the sound does not decrease as it is propagated forwards, but continues the same from the first to the last. This property of sound has been proved by repeated experiments.

When sound strikes against an obstacle, it will be reflected.

By sound we here mean the pulses in the air, which are, properly speaking, the causes of sound. If these pulses in their progress strike upon any obstacle, such as a rock, a thick wood, or the side of a building, the air, which is condensed at the obstacle, is prevented from expanding itself forwards, or from propagating the sound beyond the obstacle. Therefore, in expanding itself, the motion, which would otherwise have been propagated forwards, will be returned from the obstacle; and a person, who is placed so as to receive the pulses in their return, will hear the sound by reflection. Such a reflected sound is called an echo.

The number of syllables which an echo repeats distinctly depends upon the distance of the obstacle from whence the sound is reflected. The syllables that we hear distinctly repeated are those which are returned after we have done speaking. Therefore, if the obstacle is so near to us, that the first syllable we speak will be returned before we can speak a second, no reflected sound at all can be heard

distinctly; because the direct and reflected sound, or the voice and the echo, will be confounded with one another. If the obstacle is at such a distance, that five syllables may be spoken before one will be returned; then it we speak a sentence consisting of ten syllables, the first five will be reflected whilst we are speaking the five last, so that in speaking the five last syllables the voice will be confounded with the echo of the five first, and we shall hear the echo of only the five last syllables distinctly, because these only will be returned after we have done speaking. But if the obstacle is at such a distance, that we may speak ten syllables before the first of them will return to the speaker; then if we speak a sentence of only ten syllables, we shall have done speaking before the echo begins, and consequently we may hear the whole sentence distinctly repeated by the echo.

Sometimes the same sound is frequently repeated by an echo. This happens when there are several obstacles at different distances. For though there are several obstacles, yet if all of them are at the same distance, the sound will be returned from them all at one and the same time; and consequently the several reflected sounds will be heard together, and will make but one echo. But if the obstacles are at different distances, each will return the sound at a different time, and as many echoes will be heard as there are obstacles that produce them.

The Diving Bell.

THE air in a diving-bell is compressed by the weight of the atmosphere before the bell is let down into the water. But when it has sunk 35 feet below the surface, the air contained in it is compressed by the weight of the atmosphere as before, and by the weight of 35 feet of water besides, which is equivalent to another atmosphere. Therefore the compressing force at this depth is doubled, and consequently the air in the bell will then be twice as dense as the common air that we breathe. As much air, likewise, as just fills the bell, when it is at the surface of the water, will, at the depth of 35 feet, only fill half of it; for as the compressing force is doubled, the same quantity of air will be reduced to half its usual dimensions. For this reason, the water would rise into the bell through the base or bottom of it, which is always open, and would fill the other half of it, if there was not a contrivance for bringing down additional air enough to force out this water, and to keep the whole capacity of the bell full of air. However, the air which fills it will, at the depth of 35 feet, have twice the density that common air has; and at the depth of 70 feet, where it will be compressed by the weight of another atmosphere, it will have triple the density of common air.

We shall here give a short account of the contrivance for bringing down additional air to the diving-bell: because it will serve to shew, that if a vessel full of air is sunk into water, and the water communicates with the air in the vessel, then the pressure upon that air will be so much the greater as the vessel is sunk farther below the surface of the water. The contrivance is this. A barrel is made use of, which has one bung-hole in the lower part of it, and another in the upper part. A leathern pipe is fastened to the hole in the upper part; and this pipe is so long, that, when it hangs down on the outside of the barrel, its orifice reaches below the bung hole in the lower part. If this barrel, by the help of weights fastened to it, is made to sink with its bottom downwards, the water, by pressing against the lower

bung.

bung hole, will condense the air contained in the barrel: for, notwithstanding this pressure, none of the air can escape through the upper hole, because it is kept in by a greater pressure against the orifice of the leathern pipe which hangs below the bottom of the barrel, and consequently, being deeper in the water, sustains a greater pressure than what acts against the lower bung-hole. If the barrel is let down in this manner, till it gets below the bell, and then the end of the leathern pipe is lifted up into the bell; the lower bung-hole will then be more pressed than the orifice of the pipe; and therefore the air contained in the barrel will be driven up through the pipe, and will be received into the bell. And because the barrel is deeper in the water than the bell is, the water will press more against the base of the barrel to force the air out of it than it does against the base of the bell: for which reason the air will rush out of the barrel with force enough to drive out any water which had risen into the bell whilst it was descending.

By the same contrivance, fresh air is brought down to the bell as often as there is occasion for it. The air, which has been heated by frequently breathing it, is let out through a stop cock in the top of the bell, and rises in bubbles to the surface of the water, whilst fresh air is received from the leathern pipe of a barrel contrived in the manner already described.

Air necessary for the LI FE of ANIMALS.

ALL common air is impregnated with a certain kind of *vivifying spirit* or quality, which is necessary to continue the lives of animals: and this, in a gallon of air, is sufficient for one man during the space of a minute, and not much longer.

This spirit in air is destroyed by passing through the lungs of animals; and hence it is, that an animal dies soon, after being put under a vessel which admits no fresh air to come to it. This spirit is also in the air which is in water; for fish die when they are excluded from fresh air, as in a pond that is closely frozen over. And the little eggs of insects stopped up in a glass, do not produce their young, though assisted by a kindly warmth. The seeds also of plants mixed with good earth, and inclosed in a glass, will not grow.

This enlivening quality in air is also destroyed by the air's passing through fire; particularly charcoal fire, or the flame of sulphur. Hence smoking chimneys must be very unwholesome, especially if the rooms they are in be small and close. See *SMOKES*.

Air is also vitiated, by remaining closely pent up in any place for a considerable time; or perhaps, by being mixed with malignant steams and particles flowing from the neighbouring bodies; or lastly, by the corruption of the vivifying spirit; as in the holds of ships, in oil-cisterns, or wine-cellar, which have been shut up for a considerable time. The air in any of them is sometimes so much vitiated, as to be immediate death to any animal that comes into it.

Air that has lost its vivifying spirit is called *damp*, not only because it is filled with humid or moist vapours, but because it deadens fire, extinguishes flame, and destroys life. The dreadful effects of damps are sufficiently known to such as work in mines.

The atmosphere is the common receptacle of all the effluvia or vapours arising from different bodies; of the steams and smoke of things burnt or melted; the fogs or vapours proceeding from damp watery places; and of effluvia from

sulphureous, nitrous, acid, and alkaline bodies. In short, whatever may be called volatile rises in the air to greater or less heights, according to its specific gravity.

When the effluvia which arise from acid and alkaline bodies meet each other in the air, there will be a strong conflict or *fermentation* between them; which will sometimes be so great, as to produce a fire; then if the effluvia be combustible, the fire will run from one part to another, just as the inflammable matter happens to lie.

Any one may be convinced of this, by mixing an acid and an alkaline fluid together, as the spirit of nitre and oil of cloves; upon the doing of which, a sudden ferment, with a fine flame, will arise; and if the ingredients be very pure and strong, there will be a sudden explosion.

Whoever considers the effects of fermentation, cannot be at a loss to account for the dreadful effects of *thunder and lightning*; (see *ELECTRICITY*.) For the effluvia of sulphureous and nitrous bodies, and others that may rise into the atmosphere, will ferment with each other, and take fire very often of themselves; sometimes by the assistance of the sun's heat.

If the inflammable matter be thin and light, it will rise to the upper part of the atmosphere, where it will flash without doing any harm; but if it be dense, it will lie nearer the surface of the earth, where taking fire, it will explode with a surprising force; and by its heat rarely and drive away the air, kill men and cattle, split trees, walls, rocks, &c. and be accompanied with terrible claps of thunder.

The heat of lightening appears to be quite different from that of other fires; for it has been known to run through wood, leather, cloth, &c. without hurting them, while it has broken and melted iron, steel, silver, gold, and other hard bodies. Thus it has melted or burnt afunder a sword, without hurting the scabbard; and money in a man's pocket, without hurting his cloaths: the reason of this seems to be, that the particles of the fire are so fine, as to pass through soft loose bodies without dissolving them; whilst they spend their whole force upon the hard ones.

It is remarkable, that knives and forks which have been struck with lightening have a very strong magnetical virtue for several years after.

Much of the same kind with lightening, are those explosions, called *fulminating* or *fire-damps*, which sometimes happen in mines; and are occasioned by sulphureous and nitrous, or rather oleaginous particles, rising from the mine, and mixing with the air, where they will take fire by the lights which the workmen are obliged to make use of. The fire being kindled will run from one part of the mine to another, like a train of gunpowder, as the combustible matter happens to lie. And as the elasticity of the air is increased by heat, that in the mine will consequently swell very much, and so, for want of room, will explode with a greater or less degree of force, according to the density of the combustible vapours. It is sometimes so strong as to blow up the mine; and at other times so weak, that when it has taken fire at the flame of a candle, it is easily blown out.

Air that will take fire at the flame of a candle may be produced thus. Having exhausted a receiver of the air-pump, let the air run into it through the flame of the oil of turpentine: then remove the cover of the receiver; and holding a candle to that air, it will take fire, and burn quicker or slower, according to the density of the oleaginous vapour.

When such combustible matter, as is above-mentioned, kindles

kindles in the bowels of the earth, where there is little or no vent, it produces *earthquakes*, and violent storms or hurricanes of wind when it breaks forth into the air.

An artificial earthquake may be made thus. Take 10 or 15 pounds of sulphur, and as much of the filings of iron, and knead them with common water into the consistence of a paste: this being buried in the ground, will, in 8 or 10 hours time, burst out in flames, and cause the earth to tremble all around to a considerable distance.

From this experiment we have a very natural account of the fire of mount *Ætna*, *Veluvius*, and other volcanos; they being probably set on fire at first by the mixture of such metalline and sulphureous particles.

Of the AIR-PUMP.

THE *air-pump* being in effect the same as the *water-pump*, (see *HYDROSTATICS*.) whoever understands the one will be at no loss to understand the other.

Having put a wet leather on the plate *LL* of the *air-pump*, (Plate *CXLV*. fig. 8.) place the glass receiver *M* upon the leather, so that the hole *i* in the plate may be within the glass. Then, turning the handle *F* backward and forward, the air will be pumped out of the receiver; which will then be held down to the plate by the pressure of the external air or atmosphere. For, as the handle (fig. 9.) is turned backwards, it raises the piston *de* in the barrel *BK*, by means of the wheel *F* and rack *Dd*; and as the piston is leathened so tight, as to fit the barrel exactly, no air can get between the piston and barrel; and therefore, all the air above *d* in the barrel is lifted up towards *B*, and a vacuum is made in the barrel from *e* to *b*; upon which, part of the air in the receiver *M* (fig. 8.) by its spring, rushes through the hole *i*, in the brass plate *LL*, along the pipe *GGG* (which communicates with both barrels by the hollow trunk *IHK* (fig. 9) and, pushing up the valve *b*, enters into the vacant place *b e* of the barrel *BK*. For, where-ever the resistance or pressure is taken off, the air will run to that place, if it can find a passage.—Then, as the handle *F* will be turned forward, the piston *de* will be depressed in the barrel: and, as the air which had got into the barrel cannot be pushed back through the valve *b*, it will ascend through a hole in the piston, and escape through a valve at *d*; and be hindered by that valve from returning into the barrel, when the piston is again raised. At the next raising of the piston, a vacuum is again made in the same manner as before, between *b* and *e*; upon which more of the air, which was left in the receiver *M*, gets out thence by its spring, and runs into the barrel *BK*, through the valve *B*. The same thing is to be understood with regard to the other barrel *AI*, and as the handle *F* is turned backwards and forwards, it alternately raises and depresses the pistons in their barrels, always raising one whilst it depresses the other. And, as there is a vacuum made in each barrel when its piston is raised, every particle of air in the receiver *M* pushes out another, by its spring or elasticity, through the hole *i* and pipe *GG*, into the barrels, until at last the air in the receiver comes to be so much dilated, and its spring so far weakened, that it can no longer get through the valves: and then no more can be taken out. Hence there is no such thing as making a perfect vacuum in the receiver: for the quantity of air taken out at any one stroke, will always be as the density thereof in the receiver: and therefore it is impossible to take it all out, be-

cause, supposing the receiver and barrels of equal capacity, there will be always as much left as was taken out at the last turn of the handle.

There is a cock *k* below the pump-plate, which being turned lets the air into the receiver again; and then the receiver becomes loose, and may be taken off the plate. The barrels are fixed to the frame *Eee* by two screw-nuts *ff*, which press down the top piece *E* upon the barrels; and the hollow trunk *H* (in fig. 9.) is covered by a box, as *GH* in fig. 8.

There is a glass tube *immm* open at both ends, and about 34 inches long; the upper end communicating with the hole in the pump-plate, and the lower end immersed in quicksilver at *n* in the vessel *N*. To this tube is fitted a wooden ruler *mm*, called the *gauge*, which is divided into inches and parts of an inch, from the bottom at *n* (where it is even with the surface of the quicksilver) and continued up to the top, a little below *l*, to 30 or 31 inches.

As the air is pumped out of the receiver *M*, it is likewise pumped out of the glass tube *imn*, because that tube opens into the receiver through the pump-plate; and as the tube is gradually emptied of air, the quicksilver in the vessel *N* is forced up into the tube by the pressure of the atmosphere. And if the receiver could be perfectly exhausted of air, the quicksilver would stand as high in the tube as it does at that time in the barometer: for it is supported by the same power or weight of the atmosphere in both.

The quantity of air exhausted out of the receiver on each turn of the handle, is always proportionable to the ascent of the quicksilver on that turn; and the quantity of air remaining in the receiver, is proportionable to the defect of the height of the quicksilver in the gauge, from what it is at that time in the barometer.

EXPERIMENTS WITH THE AIR-PUMP.

I. To shew the resistance of the air.

1. THERE is a little machine, consisting of two mills, *a* and *b*, (*ibid*. fig. 10.) which are of equal weights, independent of each other, and turn equally free on their axes in the frame. Each mill has four thin arms or sails fixed into the axis; those of the mill *a* have their planes at right angles to its axis, and those of *b* have their planes parallel to it. Therefore, as the mill *a* turns round in common air, it is but little resisted thereby; because its sails cut the air with their thin edges: but the mill *b* is much resisted, because the broad sides of its sails move against the air when it turns round. In each axle is a pin near the middle of the frame, which goes quite through the axle, and stands out a little on each side of it; upon these pins, the slider *d* may be made to bear, and so hinder the mills from going when the strong spring *c* is set on bend against the opposite ends of the pins.

Having set this machine upon the pump-plate *LL* (fig. 8.) draw up the slider *d* to the pins on one side, and set the spring *c* at bend upon the opposite ends of the pins; then push down the slider *d*, and the spring acting equally strong on each mill, will set them both agoing with equal forces and velocities: but the mill *a* will run much longer than the mill *b*, because the air makes much less resistance against the edges of its sails than against the sides of the sails of *b*.

Draw up the slider again, and set the spring upon the pins as before; then cover the machine with the receiver *M* (fig. 8.) upon the pump-plate, and having exhausted the receiver of air, push down the wire *PP* (through the collar of leathers in the neck *g*) upon the slider; which will disengage it from the pins, and allow the mills to turn round by the impulse of the spring; and as there is no air in the receiver to make any sensible resistance against them, they will both move a considerable time longer than they did in the open air; and the moment that one stops, the other will do so too.—This shews that air resists bodies in motion, and that equal bodies meet with different degrees of resistance, according as they present greater or less surfaces to the air, in the planes of their motions.

2. Take off the receiver *M* (fig. 11.) and the mills; and having put the guinea *a* and feather *b* upon the brass flap *c*, turn up the flap, and shut it into the notch *d*. Then, putting a wet leather over the top of the tall receiver *AB* (it being open both at top and bottom) cover it with the plate *G*, from which the guinea and feather tongs *ed* will then hang within the receiver. This done, pump the air out of the receiver; and then draw up the wire *f* a little, which by a square piece on its lower end will open the tongs *ed*; and the flap falling down, as at *c*, the guinea and feather will descend with equal velocities in the receiver; and both will fall upon the pump-plate at the same instant. *N.B.* In this experiment, the observers ought not to look at the top, but at the bottom of the receiver; in order to see the guinea and feather fall upon the plate; otherwise, on account of the quickness of their motion, they will escape the sight of the beholders.

II. To shew the weight of the air.

1. Having fitted a brass cap, with a valve tied over it, to the mouth of a thin bottle or Florence flask, whose contents are exactly known, screw the neck of this cap into the hole *i* of the pump-plate; then, having exhausted the air out of the flask, and taken it off from the pump, let it be suspended at one end of a balance, and nicely counterpoised by weights in the scale at the other end; this done, raise up the valve with a pin, and the air will rush into the flask with an audible noise; during which time, the flask will descend, and pull down that end of the beam. When the noise is over, put as many grains into the scale at the other end as will restore the equilibrium; and they will shew exactly the weight of the quantity of air which has got into the flask, and filled it. If the flask holds an exact quart, it will be found, that 17 grains will restore the equipoise of the balance, when the quicksilver stands at 29½ inches in the barometer; which shews, that when the air is at a mean rate of density, a quart of it weighs 17 grains; it weighs more when the quicksilver stands higher, and less when it stands lower.

2. Place the small receiver *O* (fig. 8.) over the hole *i* in the pump-plate; and upon exhausting the air, the receiver will be fixed down to the plate by the pressure of the air on its outside, which is left to act alone, without any air in the receiver to act against it: and this pressure will be equal to as many times 15 pounds, as there are square inches in that part of the plate which the receiver covers; which will hold down the receiver so fast, that it cannot be got off, until the air be let into it by turning the cock *k*; and then it becomes loose.

3. Set the little glass *AB* (fig. 12.) (which is open at both ends) over the hole *i* upon the pump-plate *LL*, and put your hand close upon the top of it at *B*: then upon exhausting the air out of the glass, you will find your hand pressed down with a great weight upon it; so that you can hardly release it, until the air be readmitted into the glass by turning the cock *k*; which air, by acting as strongly upward against the hand as the external air acted in pressing it downward, will release the hand from its confinement.

4. Having tied a piece of wet bladder *b* (fig. 13.) over the open top of the glass *A* (which is also open at bottom) set it to dry, and then the bladder will be tight like a drum. Then place the open end *A* upon the pump plate, over the hole *i*, and begin to exhaust the air out of the glass. As the air is exhausting, its spring in the glass will be weakened, and give way to the pressure of the outward air on the bladder, which, as it is pressed down, will put on a spherical concave figure, which will grow deeper and deeper, until the strength of the bladder be overcome by the weight of the air; and then it will break with a report as loud as that of a gun.—If a flat piece of glass be laid upon the open top of this receiver, and joined to it by a flat ring of wet leather between them; upon pumping the air out of the receiver, the pressure of the outward air upon the flat glass will break it all to pieces.

5. Immerse the neck *cd* (fig. 14.) of the hollow glass ball *eb* in water, contained in the phial *aa*; then set it upon the pump-plate, and cover it and the hole *i* with the close receiver *A*; and then begin to pump out the air. As the air goes out of the receiver by its spring, it will also by the same means go out of the hollow ball *eb*, through the neck *dc*, and rise up in bubbles to the surface of the water in the phial; from whence it will make its way, with the rest of the air in the receiver, through the air-pipe *GG* and valves *a* and *b*, into the open air. When it has done bubbling in the phial, the ball is sufficiently exhausted; and then, upon turning the cock *k*, the air will get into the receiver, and press so upon the surface of the water in the phial, as to force the water up into the ball in a jet, through the neck *cd*, and will fill the ball almost full of water. The reason why the ball is not quite filled, is because all the air could not be taken out of it; and the small quantity that was left in, and had expanded itself so as to fill the whole ball, is now condensed into the same state as the outward air, and remains in a small bubble at the top of the ball; and so keeps the water from filling that part of the ball.

6. Pour some quicksilver into the jar *D* (fig. 15.) and set it on the pump plate near the hole *i*; then set on the tall open receiver *AB*, so as to be over the jar and hole; and cover the receiver with the brass plate *G*. Screw the open glass tube *fg* (which has a brass top on it at *b*) into the syringe *H*; and putting the tube through a hole in the middle of the plate, so as to immerse the lower end of the tube in the quicksilver at *D*, screw the end *b* of the syringe into the plate. This done, draw up the piston in the syringe by the ring *I*, which will make a vacuum in the syringe below the piston; and as the upper end of the tube opens into the syringe, the air will be dilated in the tube, because part of it, by its spring, gets up into the syringe; and the spring of the undilated air in the receiver acting upon the surface of the quicksilver in the jar, will force part of it up into the tube: for the quicksilver will follow the piston in the syringe, in the same way, and for the same reason, that wa-

er follows the piston of a common pump when it is raised in the pump-barrel; and this, according to some, is done by suction. But to refute that erroneous notion, let the air be pumped out of the receiver *AB*, and then all the quicksilver in the tube will fall down by its own weight into the jar; and cannot be again raised one hair's breadth in the tube by working the syringe *a* which shews, that suction had no hand in raising the quicksilver: and, to prove that it is done by pressure, let the air into the receiver by the cock *k* (fig. 8.) and its action upon the surface of the quicksilver in the jar will raise it up into the tube, although the piston of the syringe continues motionless. If the tube be about 32 or 33 inches high, the quicksilver will rise in it very near as high as it stands at that time in the barometer. And, if the syringe has a small hole, as *m*, near the top of it, and the piston be drawn up above that hole, the air will rush through the hole into the syringe and tube, and the quicksilver will immediately fall down into the jar. If this part of the apparatus be air-tight, the quicksilver may be pumped up into the tube to the same height that it stands in the barometer; but it will go no higher, because then the weight of the column in the tube is the same as the weight of a column of air of the same thickness with the quicksilver, and reaching from the earth to the top of the atmosphere.

7. Having placed the jar *A* (fig. 16.) with some quicksilver in it, on the pump-plate, as in the last experiment, cover it with the receiver *B* then push the open end of the glass-tube *d* through the collar of leathers in the brass neck *C* (which it fits so as to be air-tight) almost down to the quicksilver in the jar. Then exhault the air out of the receiver, and it will also come out of the tube, because the tube is close at top. When the gauge *mm* shews that the receiver is well exhaulted, push down the tube, so as to immerse its lower end into the quicksilver in the jar. Now, although the tube be exhaulted of air, none of the quicksilver will rise into it, because there is no air left in the receiver to press upon its surface in the jar. But let the air into the receiver by the cock *k*, and the quicksilver will immediately rise in the tube; and stand as high in it, as it was pumped up in the last experiment.

Both these experiments shew, that the quicksilver is supported in the barometer by the pressure of the air on its surface in the box, in which the open end of the tube is placed: and that the more dense and heavy the air is, the higher does the quicksilver rise; and, on the contrary, the thinner and lighter the air is, the more will the quicksilver fall. For, if the handle *F* be turned ever so little, it takes some air out of the receiver, by raising one or other of the pistons in its barrel: and consequently, that which remains in the receiver is so much the rarer, and has so much the less spring and weight; and thereupon, the quicksilver falls a little in the tube; but upon turning the cock, and re-admitting the air into the receiver, it becomes as weighty as before, and the quicksilver rises again to the same height. — Thus we see the reason why the quicksilver in the barometer falls before rain or snow, and rises before fair weather; for, in the former case, the air is too thin and light to bear up the vapours, and in the latter too dense and heavy to let them fall.

N. B. In all mercurial experiments with the air-pump, a short pipe must be screwed into the hole *i*, so as to rise about an inch above the plate, to prevent the quicksilver

from getting into the air-pipe and barrels, in case any of it should be accidentally spilt over the jar; for if it once gets into the pipes or barrels, it spoils them, by loosening the solder, and corroding the brass.

8. Take the tube out of the receiver, and put one end of a bit of dry hazel-branch, about an inch long, tight into the hole, and the other end tight into a hole quite through the bottom of a small wooden cup; then pour some quicksilver into the cup, and exhault the receiver of air; and the pressure of the outward air, on the surface of the quicksilver, will force it through the pores of the hazel, from whence it will descend in a beautiful shower into a cup placed under the receiver to catch it.

9. Put a wire through the collar of leathers in the top of the receiver, and fix a bit of dry wood on the end of the wire within the receiver; then exhault the air, and push the wire down, so as to immerse the wood into a jar of quicksilver on the pump-plate: this done, let in the air; and upon taking the wood out of the jar, and splitting it, its pores will be found full of quicksilver, which the force of the air, upon being let into the receiver, drove into the wood.

10. Join the two brass hemispherical cups *A* and *B* (fig. 17.) together, with a wet leather between them, having a hole in the middle of it; then screw the end *D* of the pipe *CD* into the plate of the pump at *i*, and turn the cock *E*, so as the pipe may be open all the way into the cavity of the hemispheres; then exhault the air out of them, and turn the cock a quarter round, which will shut the pipe *CD*, and keep out the air. This done, unscrew the pipe at *D* from the pump, and screw the piece *Fh* upon it at *D*; and let two strong men try to pull the hemispheres asunder by the rings *g* and *h*, which they will find hard to do; for if the diameter of the hemispheres be four inches, they will be pressed together by the external air with a force equal to 188 pounds. And to shew that it is the pressure of the air that keeps them together, hang them by either of the rings upon the hook *P* of the wire in the receiver *M* (fig. 8.) and upon exhaulting the air out of the receiver, they will fall asunder of themselves.

11. Place a small receiver *O* (fig. 8.) near the hole *i* on the pump-plate, and cover both it and the hole with the receiver *M*; and turn the wire so by the top *P*, that its hook may take hold of the little receiver by a ring at its top, allowing that receiver to stand with its own weight on the plate. Then, upon working the pump, the air will come out of both receivers; but the large one *M* will be forcibly held down to the pump by the pressure of the external air; whilst the small one *O*, having no air to press upon it, will continue loose, and may be drawn up and let down at pleasure, by the wire *PP*. But, upon letting it quite down to the plate, and admitting the air into the receiver *M*, by the cock *k*, the air will press so strongly upon the small receiver *O*, as to fix it down to the plate; and at the same time, by counterbalancing the outward pressure on the large receiver *M*, it will become loose. This experiment evidently shews, that the receivers are held down by pressure, and not by suction, for the internal receiver continued loose whilst the operator was pumping, and the external one was held down; but the former became fast immediately, by letting in the air upon it.

12. Screw the end *A* (fig. 18.) of the brass pipe *ABF* into the hole of the pump-plate, and turn the cock *a* to rise the pipe be open; then put a wet leather upon the plate *cd*, which

which is fixed on the pipe, and cover it with the tall receiver *GH*, which is close at top; then exhaust the air out of the receiver, and turn the cock *e* to keep it out; which done, unscrew the pipe from the pump, and set its end *A* into a basin of water, and turn the cock *e* to open the pipe; on which, as there is no air in the receiver, the pressure of the atmosphere on the water in the basin will drive the water forcibly through the pipe, and make it play up in a jet to the top of the receiver.

13. Set the square phial *A* (fig. 21.) upon the pump-plate; and having covered it with the wire-cage *B*, put a close receiver over it, and exhaust the air out of the receiver; in doing of which, the air will also make its way out of the phial through a small hole in its neck under the valve *b*. When the air is exhausted, turn the cock below the plate, to re-admit the air into the receiver; and as it cannot get into the phial again, because of the valve, the phial will be broke into some thousands of pieces by the pressure of the air upon it. Had the phial been of a round form, it would have sustained this pressure like an arch, without breaking; but as its sides are flat, it cannot.

To show the elasticity or spring of the air.

14. Tie up a very small quantity of air in a bladder, and put it under a receiver; then exhaust the air out of the receiver, and the small quantity which is confined in the bladder (having nothing to act against it) will expand itself so by the force of its spring, as to fill the bladder as full as it could be blown of common air. But upon letting the air into the receiver again, it will overpower the air in the bladder, and press its sides almost close together.

15. If the bladder so tied up be put into a wooden box, and have 20 or 30 pounds weight of lead put upon it in the box, and the box be covered with a close receiver; upon exhausting the air out of the receiver, that air which is confined in the bladder will expand itself so, as to raise up all the lead by the force of its spring.

16. Take the glass-ball mentioned in the fifth experiment, (fig. 14.) which was left full of water all but a small bubble of air at top, and having set it with its neck downward into the empty phial *aa*, and covered it with a close receiver, exhaust the air out of the receiver, and the small bubble of air in the top of the ball will expand itself, so as to force all the water out of the ball into the phial.

17. Screw the pipe *AB* (fig. 18.) into the pump-plate, place the tall receiver *GH* upon the plate *cd*, as in the twelfth experiment, and exhaust the air out of the receiver: then, turn the cock *e*, to keep out the air; unscrew the pipe from the pump, and screw it into the mouth of the copper vessel *CC* (fig. 22.) the vessel having first been about half filled with water. Then turn the cock *e* (fig. 18.) and the spring of the air which is confined in the upper vessel will force the water up through the pipe *AB* in a jet into the exhausted receiver, as strongly as it did, by its pressure on the surface of the water in a basin, in the twelfth experiment.

18. If a fowl, a cat, rat, a mouse, or bird, be put under a receiver, and the air be exhausted, the animal will be at first oppressed as with a great weight, then grow convulsed, and at last expire in all the agonies of a most bitter and cruel death.

19. If a butterfly be suspended in a receiver, by a fine thread tied to one of its horns, it will fly about in the receiver, as long as the receiver continues full of air; but if

the air be exhausted, though the animal will not die, and will continue to flutter its wings, it cannot remove itself from the place where it hangs in the middle of the receiver, until the air be let in again, and then the animal will fly about as before.

20. Pour some quicksilver into the small bottle *A* (fig. 19.) and screw the brass collar *c* of the tube *BC* into the brass neck *b* of the bottle, and the lower end of the tube will be immersed into the quicksilver, so that the air above the quicksilver in the bottle will be confined there, because it cannot get out about the joinings, nor can it be drawn out through the quicksilver into the tube. This tube is also open at top, and is to be covered with the receiver *G* and large tube *EF*, which tube is fixed by brass collars to the receiver, and is close at the top. This preparation being made, exhaust the air both out of the receiver and its tube; and the air will by the same means be exhausted out of the inner tube *BC*, through its open top at *C*; and as the receiver and tubes are exhausting, the air that is confined in the glass bottle *A* will press so by its spring upon the surface of the quicksilver, as to force it up in the inner tube as high as it was raised in the ninth experiment by the pressure of the atmosphere; which demonstrates that the spring of the air is equivalent to its weight.

21. Screw the end *C* (fig. 20.) of the pipe *CD* into the hole of the pump-plate, and turn all the three cocks *d*, *G*, and *H*, so as to open the communications between all the three pipes *E*, *F*, *DC*, and the hollow trunk *AB*. Then, cover the plates *g* and *h* with wet leathers, which have holes in their middle where the pipes open into the plates; and place the close receiver *I* upon the plate *g*: this done, shut the pipe *F* by turning the cock *H*, and exhaust the air out of the receiver *I*. Then turn the cock *d*, to shut out the air; unscrew the machine from the pump; and having screwed it to the wooden foot *L*, put the receiver *K* upon the plate *h*: this receiver will continue loose on the plate as long as it keeps full of air; which it will do until the cock *H* be turned to open the communication between the pipes *F* and *E*, through the trunk *AB*; and then the air in the receiver *K*, having nothing to act against its spring, will run from *K* into *I*, until it be so divided between these receivers, as to be of equal density in both; and they will be held down with equal forces to their plates by the pressure of the atmosphere, though each receiver will then be kept down but with one half of pressure upon it that the receiver *I* had when it was exhausted of air; because it has now one half of the common air in it which filled the receiver *K* when it was set upon the plate; and therefore a force equal to half the force of the spring of common air will act within the receivers against the whole pressure of the common air upon their outides. This is called transferring the air out of one vessel into another.

22. Put a cork into the square phial *A*, (fig. 21.) and fix it in with wax or cement; put the phial upon the pump-plate with the wire-cage *B* over it, and cover the cage with a close receiver. Then, exhaust the air out of the receiver; and the air that was corked up in the phial will break the phial outwards by the force of its spring, because there is no air left on the outside of the phial to act against the air within it.

23. Put a shrivelled apple under a close receiver, and exhaust the air; then the spring of the air within the apple will plump it out, so as to cause all the wrinkles disappear; but

A C H A R T, EXHIBITING

A View of the GENERAL and COASTING TRADE-WINDS, and MONSOONS or SHIFTING TRADE-WINDS, through the whole WORLD.

N. B. The arrows among the lines, shew the course of the winds. The double arrows, pointing different ways, in these places where the lines are thicker than usual, denote the monsoons, the darts always pointing the way that the wind blows in the months which are written by the darts.

N. B. The exact point where the S. E. and N. E. trade-winds meet each other near the equator, in the Pacific Ocean, is not precisely ascertained. We have therefore discontinued the lines which denote the course of the wind on each side of the equator, at some distance from it. It is generally supposed, that the south wind extends to the north of the line, as in the Atlantic Ocean: upon what authority, we know not. It seems to us more probable, that this point varies according to the course of the sun; the south wind extending to the north of the line during our summer season, and the north wind to the south of it in winter. But observations are wanting to confirm this.

Neither is it easy to ascertain, with precision, the exact boundaries between the invariable trade-winds and the monsoons in the Indian Ocean, near the line; or to say exactly, how far the monsoons, which take place to the south of the equator, extend west from Sumatra and Java.

but upon letting the air into the receiver again, to prefs upon the apple, it will instantly return to its former decayed and shrivelled state.

23. Take a fresh egg, and cut off a little of the shell and film from its smallest end; then put the egg under a receiver, and pump out the air; upon which, all the contents in the egg will be forced out into the receiver, by the expansion of a small bubble of air contained in the great end, between the shell and film.

34. Put some warm beer in a glass; and having set it on the pump, cover it with a close receiver, and then exhaust the air. Whilst this is doing, and thereby the pressure more and more taken off from the beer in the glass, the air therein will expand itself, and rise up in innumerable bubbles to the surface of the beer; and from thence it will be taken away with the other air in the receiver. When the receiver is near exhausted, the air in the beer, which could not disengage itself quick enough to get off with the rest, will now expand itself so, as to cause the beer to have all the appearance of boiling; and the greatest part of it will go over the glass.

25. Put some warm water in a glass, and put a bit of dry waincot or other wood into the water. Then, cover the glass with a close receiver, and exhaust the air: upon which, the air in the wood having liberty to expand itself, will come out plentifully, and make all the water to bubble about the wood, especially about the ends, because the pores lie lengthwise. A cubic inch of dry waincot has so much air in it, that it will continue bubbling for near half an hour together.

OF WINDS.

AS the air is a fluid, subjected to the same laws of gravitation as other fluids, it necessarily has a constant tendency to preserve an equilibrium in every part; so that, if by any means whatever it is rendered lighter in any one place than another, the weightier air will rush in from every side towards this place, till as much be there accumulated as makes it of an equal weight with the rest of the atmosphere: It is these currents of air which are called *winds*.

Many are the causes which may vary the weight of the atmosphere, and occasion particular topical winds.

Although other causes may occasion winds in certain circumstances, yet their principal and most universal cause is the sun, which warmeth the air to a much greater degree in some places of the atmosphere than in others; and as the air is susceptible of a great degree of expansion by heat in those places where it is heated to any considerable degree, it is expanded so much as to become lighter than the air in those places where it is colder; so that the weightier cold air from all the circumjacent parts rushes towards this point to restore the equilibrium which had been destroyed. So that if there be any particular part upon the earth's surface where the sun acts constantly with greater force than on any other part, a current of air will constantly flow from these towards the warmer region; but the sun acts with greater force upon those parts of the earth which are nearest the Equator, than those which approach towards either Pole; so that we might naturally expect that a wind would constantly blow from the polar regions towards the Equator; which is really found to be the case in the *Torrid Zone*, where the influence of the sun overcomes almost all the other lesser causes which produce the variable winds in our

more northerly regions. However, even in the *Torrid Zone*, these north and south winds are varied in different ways.

Although the heat of the equatorial region is greater than any other; yet as the sun acts perpendicularly in his diurnal course upon one point of the equator only at one time, and immediately passes over it; and as the air retains the heat communicated to it by the sun but for a short time, cooling gradually as he retires, and continuing still to decrease till his influence again returns the following day; the degree of heat upon this great circle must be very different in different parts, and perpetually varying in every point; which must in some measure tend to disturb those winds coming from the polar regions, which we have already mentioned. To comprehend clearly what will be the effects of this rotation, let us consider what effect it would naturally produce upon the equator with regard to wind, supposing no other cause should interrupt it. And here we must observe, that as the point upon which the sun acts with the greatest power is constantly moving from east to west, the air to the east of that point over which the sun has more lately passed will be more rarefied than that to the west, and will naturally flow towards that point from east to west with greater velocity than from west to east, as the cool air to the west of that point will be interrupted in its motion towards it by the motion of the sun meeting it. Hence therefore it follows, that from the diurnal motion of the earth from west to east a constant east wind would always be produced, were it not obstructed by other causes. But as there is a constant stream of air flowing from the polar towards the equatorial regions, a composition of these two currents of air acting at the same time will produce a north-east wind in all parts of the northern hemisphere, and a south-east wind in all parts of the southern one. These winds are known by the name of the *general trade-winds*.

If there were no inequalities on the surface of our globe, and if it were composed of a substance perfectly homogeneous, this wind would invariably take place at all times on every part of the earth's surface; but as this is not the case, it is liable to several very considerable variations. In all those regions towards the poles, as the influence of the sun is there but weak, other lesser causes occasion particular winds, and disturb that regularity which at first view we might expect, so that the *general trade wind* does not invariably take place beyond the 28th or 30th degree of latitude; and the regions between that and the poles have nothing but variable winds. Even in the *Torrid Zone*, there are many causes which in particular places alter this direction of the wind; so that the *genuine trade-winds* do not take place except in the Atlantic and Pacific oceans on each side the equator to the distance of 28 or 30 degrees, and in the greatest part of the Indian ocean to the south of the Equator as appears, more distinctly upon the Map; see Plate CXLVI. where the course of the winds are marked by the direction of the *strokes*, the *darts* pointing in the same direction as the wind blows.

Having thus explained the nature and causes of the general trade wind, we now proceed to take notice of the principal deviations which take place in the *Torrid Zone*. The general trade-wind, when thus altered at particular seasons, is known by the name of *monsoons*. There are other variations, which, although as general, are yet of smaller and more limited influence. These are known by the name of *breezes*; and as they blow periodically from the sea, they are denominated *sea or land breezes*, and take place more

ful blast, so as to produce the intemperate monsoon which here takes place between the months of *April* and *October*.

From *Mozambique*, to cape *Guardafoy*, at the mouth of the *Red Sea*, the monsoons are a little more irregular than in the other parts of the *Indian ocean*. For it is observed, that between *October* and *January* the winds are variable, although chiefly from the north. In *January* the N. E. monsoon sets in, and continues regular till the month of *May*. From *May* till *October* the winds again become variable, but blow chiefly from the southern points; but in the months of *June*, *July*, and *August*, there are frequent calms, especially about the bay of *Melinda*, which sometimes continue for several weeks together, and extend only about a hundred leagues from shore.

Before we can explain the cause of this irregularity clearly, it will be necessary to attend to the direction of the wind on each side of this track at each particular season. In the months of *October*, *November*, and *December*, the winds are here variable, but chiefly from the north. Now during these three months, the wind to the south of this beyond *G. Corientes* blows from the S. E. at the *Red Sea*, and all to the north of this the wind during this season of the year is from the N. E. And as the sun is then perpendicular to the bay of *Melinda*, these opposite winds here meeting and opposing one another, and being both of them flopt in their course westward by the cold regions of *Africa* near the Mountains of the Moon, will naturally produce the variable winds here observed according as the one or the other of these balancing powers shall predominate: although, as the coast here runs away towards the south-west, it is natural to expect that the northerly wind, which follows the same direction, should more frequently prevail than those which are opposed by it; especially when we consider, that the island of *Madagascar*, now beginning to be warmed by the influence of the sun, will concur in drawing the wind to the southward; and when the continent of *Africa* is more heated in the months of *January* and *February*, it does not oppose the easterly monsoon, so that the winds become then more fixed than before. But in the months of *June*, *July*, and *August*, the wind to the south of *G. Corientes* is from the N. W.; and near the *Red Sea*, and throughout the northern part of the *Indian ocean*, the S. W. monsoon is then in its greatest vigour; so that on each end of this district the wind is blowing in an opposite direction; from which results these calms about *Melinda*, which we just now mentioned.

This much may suffice for the shifting winds on the *African* and *Asiatic* coasts. As to *America*, the only places where the wind shifts regularly are, the bays of *Honduras* and *Campeachy* on the east, and that of *Panama* and some parts on the coast of *Mexico* on the west, with a small track upon the coast of *Brazil*. In the south part of the bay of *Honduras*, between *G. Gratia de Dios* and *C. la Bella*, the common trade-wind between E and NE blows between *March* and *November*; from *October* till *March*, there are westerly winds; not constant, or violent, but blowing moderately sometimes two or three days, or a week; and then the easterly breeze may again prevail for an equal length of time. The reason of the peculiarity here observed is this. During the summer season, the high land on the *Isthmus of Darien* is so much warmed as not to interrupt the course of the general trade-winds. But

when he retires to the southern Hemisphere, the cold upon the *Isthmus* at that season becomes so great, as to condense the air to such a degree as to repel the trade-wind for some time: but not being cooled to such an intense degree as in some of the larger continents, the trade-wind at times overcomes and repels these land breezes in its turn, and produces the phenomena above described. And that this is really the case, appears evident from this circumstance, that the land-breezes are most prevalent and of longest duration in the coldest months of *December* and *January*; before and after which two months, the trade-wind being generally checked, only a day or two about the full or change of the moon. As these western breezes on this coast take their rise from the same cause as the diurnal land breeze in warm climates, they may be considered as *land-breezes* of two or three days continuance, and forming an intermediate step between the *land-breezes* and *monsoons*. Although the influence of these breezes is felt farther off at sea than the common diurnal breeze, yet they do not extend a great way, being seldom felt above twenty or thirty or forty leagues from shore: and about *C. La Vela*, which is much exposed to the east wind, these breezes extend above eight or ten leagues from shore. Land breezes of the same nature, and proceeding from similar causes, are also experienced in the winter season in the bay of *Campeachy* which are there known by the name of *Summerfanta* winds. Beyond *C. la Vela* these western breezes are not felt, which is undoubtedly occasioned by the whole of that coast as far as *C. St Augustine* being so much exposed to the general trade-wind, which here sweeps along the coast with so much violence as almost totally to repress the weaker influence of the breezes. But between *C. St Augustine* and *St Catharine's island*, or a little farther, we again meet with a variation of the wind at different seasons, as it is here observed to blow in an E or NE direction from *September* till *April*; and from *April* till *September* from the SW. This variable wind, or monsoon, like the others on this coast, extends but for a very short way from shore, and is evidently occasioned by the same causes as the other periodical winds. For, in the summer-months, (which in this climate is between *September* and *April*, the land of the continent being heated by the sun, draws the trade-wind from its common course of SE, a little to the westward; and as the coast here tends towards the SW, the wind in some measure (as it always does) follows the same direction, and produces this ENE monsoon. But, in the winter, when this region becomes more cool, the east wind is repelled by the dense cold air from the mountains; by which means it is bent to the northward, and is forced along the coast to *C. St Augustine*; where meeting with no further hindrance, it again falls in with the general trade-wind, and is carried along with it in its proper direction.

We have purposely omitted mentioning the winds on the west coasts of *Africa* and *America*, till the others were explained, as the causes of the peculiarities here observed will be now more easily comprehended. On the coasts of *Chili* and *Peru*, in *America*, from 25° or 30° of south latitude to the line; and on the parallel coast of *Angola*, &c. in *Africa*, the wind blows all the year from the south, varying in its direction, a little in different places according to the direction of the coast, towards which it always inclines a little. But whatever is the direction at any one place, it continues the same throughout the whole year without any

any variation, and always blows from some southerly point. But there is this difference between this wind upon the coasts of *Chili* and *Angola*, that it extends much farther out to sea upon the former than upon the latter.

In order to explain the cause of this singular phenomenon, it is necessary to recollect, that the general trade-wind is produced by the concurrence of two separate causes. One is the great heat of the equatorial region, by which alone would be produced a constant north or south wind. The other is the diurnal revolution of the earth, which would cause a perpetual tendency of the air in these warm regions from east to west. From the concurrence of these two causes result the general trade-wind, which would constantly blow from the SE or NE, as we have already demonstrated. But if any one of these two causes, in any particular place, is prevented from producing its full effect, while the other continues to exert its influence, the general direction of the wind will be varied, and it will assume another. Thus, if the east wind was prevented from acting in any particular place, while nothing interrupted the south or north wind, it is evident that the air would rush towards the equator in that direction which was nearest and easiest, whether that should be pointing eastward or westward. Now as the high mountains in the internal parts of *Africa* and *America* interrupt the course of the east wind near the surface of the earth, while these coasts of which we now treat are entirely open to the south, the wind naturally rushes along the coasts of *Chili* and *Angola* from north to south; and as the low lands near the shore, in these warm regions, is generally warmer than the sea, the wind will naturally point in towards the shore, as is generally observed to happen.

This, then, is the obvious cause of the south wind which always prevails upon the coasts of *Chili* and *Peru*, as well as along the shores of *Angola*, *Loango*, &c. But it is only near the shore that this can take place; nor can it extend to a great height above these low and fertile regions. For as the internal parts of these countries are exceedingly high; but more especially the *Andes of America*, which experience a perpetual degree of cold more intense than some polar regions ever experience; the air must here be condensed to a very great degree, and send forth from these high regions a perpetual wind to every side, which occasions almost all the peculiarities that have been remarked in these climates: For by opposing the general current of the trade-wind upon the eastern part of these continents, they produce these deluges of rain which supply the immense rivers of the *Amazon*, *La Plata*, &c. these do not, like the *Nile* and *Gambia*, swell only at a particular season, and then shrink into a diminutive size again, but continue throughout the whole year, with less variation of size, to pour their immense floods of water into the ocean. These cold winds likewise stretching to the westward, at a considerable distance above the warmer regions of the sea-coast, at length descend as low as the ocean, and form the general trade-wind, and occasion that unusual degree of cold which mariners have so often complained of even under the line to the westward of America. To the same cause also must we attribute the thick fogs so common upon the southern parts of *Chili* and along the coasts of *Peru*, with the other peculiarities of that singular climate about *Lima* and the kingdom of *Valley* in South America; for the vapours which are exhaled in such great abundance in the warm regions on the

sea shore, are, at a little height above the earth, condensed by the cold winds which come from the mountains, and form these thick mists which are so often observed in this climate. The same effects are felt in some degree on the similar coast of *Africa*. But as the mountains of *Africa* are not so high as the *Andes of America*, nor approach so near the western coast, the effects are less sensible here than in *America*. The great height of the *Andes* above the mountains of the similarly situated country of *Africa*, is the only reason why the effects on that coast are not felt to an equal degree, although similar in kind.

A more singular deviation from the general trade wind is observed to take place on the *African* and *American* coasts to the north of the line, than those we have taken notice of to the south of it. For it is observed, that from *California* to the bay of *Panama*, all along the coasts of *New Spain*, the winds blow almost constantly from the west or SW, nearly directly opposite to the trade-wind; and on the coast of *Africa* from *C. Bayador* to *C. Verde*, they blow chiefly from the NW, standing in upon the shore; from thence the wind bends gradually more and more from the north to the west, and so round to the SW, all along the coast of *Guinea*, as will be distinctly seen by the map. After what we have said of the winds on the southern parts of these regions, it will be unnecessary to spend much time in explaining the cause of these peculiarities, as it will evidently appear that they are nearly the same, the variations here observed being occasioned by the particular direction of the coast. Thus, along the coast of *New Spain*, the wind blows nearly the same direction in every place, as there are no remarkable bendings on the coast; being uniformly drawn towards the shore, by the great heat of the low part of the continent near the sea; which in these regions is always more heated than the water of the ocean, and occasions that infection. But as the coast of *Africa* is more irregular, the winds also are found to be more different in their direction. To the north of *C. Verde*, as the coast stretches nearly south and north, the wind, being drawn towards it a little, blows from the NW. But beyond that, the coast bends more eastward to *C. Palmas*; from which it runs E or NE all along the coast of *Guinea*, the wind shifting gradually more and more to the west, still pointing in upon the coast. And as there is nothing to oppose the current of air, which comes from the south, along the coast of *Angola*, it stretches forward till it comes within the influence of the coast of *Guinea*, and is there drawn in towards the shore in a SW direction. But as it is only the lower regions of the coast of *Guinea* which are so much warmed, the high mountains within continuing cold the northerly wind coming from these meeting and opposing the southerly winds in the higher regions of the air, by their mutual conflicts occasion those incessant rains and tremendous thunder so remarkable along the whole of this uncomfortable coast.

It has been often observed by mariners, that there is a track of sea to the west of *Guinea* from five to ten degrees of north latitude, in which the trade wind blows with less steadiness than in any other part of that ocean, being almost constantly troubled with calms and tornadoes; the cause of which the reader will perceive by inspecting the map: as he will easily see, that the winds are drawn from this quarter almost in every direction; so that there can be here no constant wind; but being exhausted of its air, it must become lighter than the circumjacent parts; and must then be sup-

plied from either side, as chance or occasional circumstances may direct, which occasions those sudden flurries and tornadoes here observed.

Before we take our leave of this subject, it is necessary to observe, that in the Bay of *Panama*, the winds between *September* and *March* are easterly; but from *March* till *September* they blow chiefly from the SSW; that is, during the winter months, while the sun is far from them, the winds are off shore; and during the summer months, the land being heated to a considerable degree, they are drawn towards the shore as usual. It is remarkable, however, that this is the only part on the west of a large continent where the wind shifts regularly at different seasons; which seems to be occasioned by the great height of the *Isthmus of Darien*, and the *Terra Firma* to the east of it, and the nearness of these to the sea, in comparison of the mountains near *Benin* on the similarly situated coast of *Africa*; which is greatly assisted by the deepness of the bay, which, by bending so much to the eastward from *C. Lorenzo*, is in a great measure screened from the force of the south winds, which allows the winter breeze to extend itself upon the bay with more facility. We ought here also to remark, that along the coast of *Mexico*, between *C. Pelanco* and *Guatemala*, there are land winds which blow in the months of *May*, *June*, and *July*, called by the Spaniards *Popogaio*s. They greatly resemble the *Summasenta* winds in the *Bay of Campeachy*, as they blow both night and day a moderate breeze without intermission, sometimes three or four days or a week together. But as these blow from the land in summer only, whereas the *Summasenta*'s blow only in winter, they must be occasioned by a different cause; which seems to be this: As the continent which divide the south sea from the *Bay of Mexico* and *Gulf of Honduras*, is but of very small breadth, and in many places very high ground, the heat which it receives from the sun in summer is not so great as on the similar coast of *Africa*; and as the trade-wind coming from the great *Atlantic* ocean sweeps along the eastern part of the *American* coast from *C. St Augustine* to the *Bay of Honduras* with very great violence at that season, the small heat of this narrow continent, is not sufficient to stop it entirely during that season; so that at some times it blows for a short time quite across it, and occasions those winds called *Popogaio*s.

Besides these more general winds, there are likewise some particular winds which are only felt in particular places at certain times, whose effects are so singular as to merit attention; some of which we shall here take notice of. In the *Gulf of Persia*, particularly at *Ormuz*, during the months of *June* and *July*, there sometimes blows from the west, for a day or two together, a hot suffocating fiery wind, which scorches up and destroys any animal that may be exposed to it; for which reason, almost every body leave their habitations at *Ormuz* during these two months, and retire to the mountains near *Schiras* in *Persia*, where they enjoy a more comfortable climate. To explain the cause of which, it is necessary to observe, that along all the coasts of *Asia*, to the north of the *Indian ocean*, the diurnal sea and land breezes take place, as in every part of the torrid zone; by means of which, the monsoons are not felt close in upon the shores. But as the monsoon continues to blow regularly at a small distance from shore, so in all probability it continues its course without inter-uption at a small distance above the surface of the earth. Now when the monsoon is in its greatest vigour, its influence will sometimes de-

scend even as low as the surface of the earth, and, interrupting the course of the breezes, hurry along with it these warm vapours, which ought to have ascended upwards, and produced the salutary sea-breeze; and as the earth is thus deprived of the refreshing influence and moisture of the sea-breeze, the air, by the strong reverberation of the sun-beams from such dry and sandy countries as *Arabia*, must soon be heated to an amazing degree, and produce these hot and suffocating winds. It is also remarkable, that these hot winds are more often experienced near headlands, where the sea-breezes are weakest, which seems to confirm this hypothesis. Winds similar to these in kind, though not in degree, are felt upon the coast of *Coromandel* during the months of *June*, *July*, and *August*, while the west monsoon reigns; and on the *Malabar* coast they are likewise felt in the months of *December* and *January*, while the east monsoon reigns; but these are much less powerful than either of the others. As these hot winds always come from the land, they are known upon these coasts by the name of *Terronols*.

It has likewise been observed, that on the coast of *Africa* to the north of *C. Verde*, during the months of *December*, *January*, and *February*, there sometimes blows, for a day or two together, an easterly wind, so very intensely cold as to be almost as destructive as the warm winds at *Ormuz*. We have already in some measure explained the cause of this phenomenon. During these months, when the sun is far from them, his influence is less felt than at other seasons, and the northerly wind upon the coast is of course weakened, inasmuch that the cold produced by the mountains in the heart of the country being now in its greatest degree of force, bursts its usual confinement for a time, spreading to the west with great violence, and producing those uncommon effects already mentioned. Those who sail on these coasts, distinguish this particular wind by the name of *Hermatan*.

These are the principal winds, whether constant or periodical, that take place within the tropics; and thus simple are their causes.

The succession of sea and land breezes renders the Torrid Zone not only habitable but comfortable. Besides, as these currents of cold air, rushing from each side of the globe, and carrying along with them vast quantities of aqueous vapours which they collect from the surface of the earth in their course, meet and oppose one another at that part of the atmosphere where the influence of the sun is greatest at the time, the water is there forced from the clouds in such prodigious quantities, as to produce a diversity of seasons in the Torrid Zone, something similar to what is experienced in more temperate climates; with this difference however, that whereas, in temperate climates, the warmest and most comfortable season is when the sun approaches nearest perpendicular to them, in these warmer climates the heavy rains which fall upon them at that season moderates the heat, and prevents the sun from having such an effect as at other times; so that their coldest and most inconsistent weather, which they call *winter*, is at that season, when, without this cause, they would be exposed to the sun's most powerful influence.

We shall only take notice of one other instance of the happy effects produced on our globe, by the laws of nature with respect to winds. We have seen, that in the great *Atlantic* and *Pacific* oceans, the trade-wind blows constantly from the easterly points throughout the whole year, so that ships

ships sail from *east* to *west* within the tropics with the utmost facility; but it is absolutely impossible in these seas to sail from *west* to *east*, as the wind would be constantly against them; so that ships bound for any port to the *eastward* in these regions, must stand to the *north* or *south* till they are beyond the limits of the *trade-winds*, where they meet with *variable breezes*, by the help of which they sail to the *eastward*. But if the same constant *trade-wind* had taken place in the northern part of the *Indian Ocean*, it would have been impossible to have sailed to the *eastward* at all; because the continent of Asia would have prevented the ships from sailing far enough north to find the variable winds. But here, as in almost every case in which the operations of nature are concerned, we find, that what produceth the disease, at the same time furnisheth a remedy: for that very continent which would have stood in our way going northward,

draws the wind towards itself at one season, which makes that course of navigation unnecessary, the shifting of the *monsoons* supplying a nearer and more commodious course. Thus we see, that where ever the sea is open to the south or north, near the *tropics*, so as that ships are at freedom to reach the *variable winds*, the *trade-wind* constantly blows in one direction; but where-ever there is any extent of continent within the verge of the *Torrid Zone*, so as that they could not be at liberty to reach the variable winds, there the course of the trade wind is altered, being drawn towards it in summer, and from it in winter, forming that shifting wind called *monsoons*. From which we may naturally infer, that as there are no *monsoons* in the *Pacific* or *Atlantic*, or in the western part of the *Indian* ocean, to the south of the *line*, there are no extensive continents near the tropics in either of these places.

P O E

P O E

PNEUMATOCELE. See **MEDICINE** and **SURGERY**.
PNEUMONICS, in pharmacy, medicines proper in diseases of the lungs, in which respiration is affected.

PO, a great river of Italy, rising in the Alps, and running first east, soon after turns directly north, through Piedmont, where it receives the Doria; then passing north east, it discharges itself by several channels into the gulf of Venice.

POA, in botany, a genus of the triandria digynia class. The calix has two valves including several flowers; the spike is oval, with pointed leaves. There are 20 species, twelve of them natives of Britain.

POCHARD, in ornithology. See **ANAS**.

PODAGRA, in medicine, the gout in the feet. See **MEDICINE**.

PODALIA, a province of Poland, bounded by Volhnia, and the Russian Ukrain, on the north and north-east; by Budziac Tartary, on the south-east; by the river Niefter, which separates it from Bessarabia and Moldavia, on the south-west; and by the province of Red-Russia, on the north-west.

PODENSTEN, a town of Germany, in the circle of Franconia: situated in E. long. 11° 35', N. lat. 49° 50'.

PODEX, in anatomy. See **ANUS**.

PODOPHYLLUM, in botany, a genus of the polyanthia monogynia class. The corolla has nine petals, and the calix three leaves; the capsule is oval and unilocular. There are two species, none of them natives of Britain.

POEM, a composition in verse of a due length and measure.

Poems are generally denominated from the subject-matter, as the apobaterion, epibaterion, epinicion, epithalamium, genethliac, elegiac, satiric, epitaph, panegyric, lyric, pastoral, &c. and others from the manner of narration, as epic, dramatic, &c. to which may be added odes, eclogues, and idylliums. To this head may also be referred several other compositions of a less serious kind, as the acrostic, enigma, anagram, cento, echo, &c.

POET, the author of a poem. See **POEM**.

POETRY, the art of composing poems, or pieces in verse; or, as defined by Vossius, the art of representing actions in metre.

Vossius thinks that love was the first occasion of poetry; which is not improbable, considering that this affection is coeval with mankind, is universal, and naturally productive of poetry. Yet it undoubtedly owes its increase and progress to religion. Dacier indeed calls it the offspring of religion; and it is certain, in the earliest ages of the world, that it was usual to sing hymns to the honour of the gods upon solemn festivals. Du Bos thinks that poetry has been employed in all ages, even by the most unpolished nations, to preserve the memory of past events. Its principal aim is to flatter our senses and imagination: for, according to Plato, it awakes the spiritual empire of the soul. Every kind of poetry charms us in proportion to its object, says Du Bos: and to be very affecting, it ought to be very exact. It is not the same with poetry as with other arts; for an ignorant person may judge of poetry by the impression it makes on him: whence all men have a right to give their opinion concerning a piece of poetry, and this judgment ought to be founded on experience rather than on argumentation. Poetry is an art where every thing should please. It is not enough to exhibit nature, which in certain places and circumstances is rude and unpleasant; but the poet must chuse in her what is beautiful from what is not: whence a poet ought to chuse, for the subject of his imitation, something that is naturally affecting. There is a particular rhetoric for poetry, which consists in discerning very precisely what ought to be said figuratively, and what to be spoken simply; and in knowing where ornament is required, and where not: yet the style should be copious, and every species of writing in this art should have a diction proper to itself. The qualifications, then, necessary for poetry, or those which form a good poet, are seldom found united in one person: he must have an extraordinary genius, great natural gifts, a wit just, piercing, solid, and universal; an understanding clear and distinct; an imagination neat and pleasant; an elevation of soul that depends not on art, or study, and which is purely a gift of heaven, and must be sustained by a lively sense and vivacity, a great judgment to consider wisely of things, and a vivacity to express them with that grace and abundance which gives them beauty. In fine, to accomplish a poet, is required a temperature of wit and fancy, of strength and sweetness, of penetration and delicacy; but, above

- all, he must have a sovereign eloquence, and a profound capacity. These are the qualities that must concur together to form the genius of a poet, and sustain his character.
- POICTIERS**, the capital of Poitou, in France, situated on an eminence, near the river Clain: E. long. 15', N. lat. 46° 40'.
- POICOU**, a territory of France, in the province of Orléans, situated south of the river Loire, being bounded by the provinces of Anjou and Brittany on the north, by Touraine and Berry on the east, by Santoign, Angoumois, and Anjou on the south, and by the ocean on the west. It is one hundred and fifty miles long, and seventy broad.
- POINCIANA**, in botany, a genus of the decandria monogynia class. The calix consists of five leaves, and the corolla of five petals; the stamina are long. There are three species, all natives of India.
- POINT**, a term used in various arts.
- POINT**, *punctum*, in geometry, as defined by Euclid, is a quantity which has no parts, or which is indivisible.
- POINT**, in grammar, a character used to mark the divisions of discourse.
- POINTS**, in heraldry, are the several different parts of an escutcheon, denoting the local positions of any figure. There are nine principal points in an escutcheon, as represented in Plate CXLV. fig. 2. where A shews the dexter chief; B, the precise middle chief; C, the sinister chief; D, the honour-point; E, the fess-point, called also the centre; F, the nombril-point, that is, the navel-point; G, the dexter base; I, the sinister base; H, the precise middle base.
- POISON**, in medicine. See **MEDICINE**, p. 152.
- POLAND**, a large kingdom of Europe, situated between 16° and 34° east longitude, and between 46° and 57° north latitude; bounded by Russia on the north and east; by Besarabia, Moldavia, Transilvania, and Hungary, on the south; and by Pomerania, Brandenburg, and Silesia, on the west; being almost square, and seven hundred miles over either way.
- POLAR**, in general, something relating to the poles of the world, or poles of the artificial globes: thus we meet with polar circles, polar dial, polar projection, &c.
- POLARITY**, the quality of a thing considered as having poles; but chiefly used in speaking of the magnet.
- POLE**, in astronomy, one of the extremities of the axis on which the sphere revolves.
- POLE**, **PERCH**, or **ROD**, in surveying, is a measure containing sixteen feet and a half.
- POLE**, or **POLAR STAR**, is a star of the second magnitude, the last in the tail of ura minor. See **ASTRONOMY**, p. 486.
- POLE CAT**. See **MUSTELA**.
- POLEMICAL**, in matters of literature, an appellation given to books of controversy, especially those in divinity.
- POLEMONIUM**, in botany, a genus of the pentandria monogynia class. The corolla consists of five segments; the stigma is trifid; and the capsule has three cells. The species are five, only one of which, *viz.* the *caruleum*, or great valerian, is a native of Britain.
- POLIANTHES**, in botany, a genus of the hexandria monogynia class. The corolla is bell-shaped; and the filaments are inserted into the fauce. There is but one species.
- POLICY**, or **POLITY**, in matters of government. See **POLITY**.
- For policies of assurance, or insurance on ship, houses, lives, &c. see **INSURANCE**.
- POLISHER**, or **BURNISHER**, among mechanics, an instrument for polishing and burnishing things proper to take a polish. The gilders use an iron-polisher to prepare their metals before gilding, and the blood-itone to give them the bright polish after gilding.
- POLISHING**, in general, the operation of giving a gloss or lustre to certain substances, as metals, glass, marble, &c. See **METAL**, **GLASS**, &c.
- POLITICS**, the first part of oeconomy, consisting in the well governing and regulating the affairs of a state, for the maintenance of the public safety, order, tranquillity, and morals.
- POLITY**, or **POLICY**, denotes the peculiar form and constitution of the government of any state or nation; or, the laws, orders, and regulations, relating thereto.
- Polity differs only from politics, as the theory from the practice of any art.
- POLL**, a word used in ancient writings for the head: hence to poll, is either to vote or to enter down the names of those persons who give in their votes at an election.
- POLLACK**, in ichthyology. See **GADUS**.
- POLLEX**, in anatomy, denotes either the thumb or great toe, according as any manus or pedis is added to it. See **ANATOMY**.
- POLLUX**, in astronomy, a fixed star of the second magnitude in the constellation gemini, or the twins. See **ASTRONOMY**, p. 487.
- POLOCZK**, the capital of the palatinate of the same name, in the duchy of Lithuania, in Poland: E. long. 29°, N. lat. 56° 30'.
- POLYACANTHA**, in botany. See **CARDUUS**.
- POLYADELPHIA**, in botany. See **BOTANY**, p. 635.
- POLYANDRIA**, in botany. See **BOTANY**, p. 635.
- POLYANTHUS**, in botany. See **PRIMULA**.
- POLYCHREST**, in pharmacy, signifies a medicine that serves for many uses, or that cures many diseases.
- Sal POLYCHREST**, a compound salt made of equal parts of salt petre and sulphur, laid on a red-hot crucible.
- POLYCNEMUM**, in botany, a genus of the triandria monogynia class. The calix consists of three leaves, and the corolla of five petals; and it has but one round seed. There is but one species, a native of Germany.
- POLYGALA**, in botany, a genus of the diadelphia octandria class. The calix consists of five leaves; and the pod is cordated, and has two cells. There are 24 species, only one of them, *viz.* the vulgaris, or milk-wort, a native of Britain.
- POLYGAMIA**, in botany. See **BOTANY**, p. 635.
- POLYGAMY**, a plurality of wives or husbands, in the possession of one man or woman, at the same time.
- Many arguments have been offered to prove the unlawfulness of polygamy; one of the principal of which is, that the males and females brought into the world are nearly on a balance; only abating for a small excess on the side of the males, to make up for the extraordinary expence thereof in war and at sea: whence it evidently follows, that nature only intends one wife, or one husband, for the same person; since if they have more, some must go without any at all. Hence it is justly concluded, that

that the Christian law, which prohibits polygamy, is more agreeable to the law of nature than the Mahometan, and, we may add, than the Jewish law, by which polygamy was tolerated.

POLYGLOTT, among divines and critics, chiefly denotes a bible printed in several languages. See **BIBLE**.

POLYGON, in geometry, a figure with many sides, or whose perimeter consists of more than four sides at least: such are the pentagon, hexagon, heptagon, &c.

POLYGONATUM, in botany. See **CONVALLARIA**.

POLYGONUM, in botany, a genus of the octandria trigynia class. It has no calix; the corolla has five segments; and there is but one angular seed. The species are 27, eleven of them natives of Britain.

POLYGYNIA, among botanists. See **BOTANY**, p. 635.

POLYHEDRON, in geometry, denotes a body or solid comprehended under many sides or planes.

POLYHEDRON, in optics, is a multiplying glass or lens, consisting of several plane surfaces disposed into a convex form. See **OPTICS**.

POLYMATHY, denotes the knowledge of many arts and sciences.

POLYMNIA, in botany, a genus of the syngenesia polygamia necessaria class. The receptacle is paleaceous; it has no pappus; and the calix consists of ten leaves. There are two species, both natives of America.

POLYPUS, in zoology, a species of the hydra, which, although cut in a thousand pieces, and in every direction, still exists, and each section becomes a complete animal.

POLYPETALOUS, among botanists, an epithet applied to such flowers as consist of several petals, or flower-leaves.

POLYPODIUM, in botany, a genus belonging to the cryptogamia filices class. The fructifications are disposed in round spots on the margin of the leaf. There are 65 species, 14 of them natives of Britain.

POLYPREMUM, in botany, a genus of the tetrandria monogynia class. The calix consists of four leaves, and the corolla, which is rotated, of four segments; the capsule is compressed, and bilocular.

POLYPUS of the heart. See **MEDICINE**, p. 158.

POLYSYLLABLE, in grammar, a word consisting of more syllables than three; for when a word consists of one, two, or three syllables, it is called a monosyllable, dissyllable, and trisyllable.

POLYTHEISM, in matters of religion, the doctrine or belief of a plurality of gods.

POLYTRICHUM, in botany, a genus of the cryptogamia musci class. The anthera is operculated, and the calyptra hairy. There are three species, one of them, *viz.* the commune, or great golden maidenhair, a native of Britain.

POMEGRANATE. See **PUNICA**.

POMERANIA, a province or Upper Saxony, in the north of Germany; bounded by the Baltic-sea, on the north; by Poland, on the east; by another part of Poland, and Brandenburg, on the south; and by the duchy of Mecklenburg, on the west.

POMME, or **POMMETTE**, in heraldry, is a cross with one or more balls or knobs at each of the ends.

POMMEL, or **PUMMEL**, in the menage, a piece of brass, or other matter, at the top and in the middle of the saddle-bow.

POND-WEED, in botany. See **POTAMOGETON**.

PONDICHERRY, a town of India, on the Coromandel-coast, sixty miles south of Fort St. George.

PONTEDERIA, in botany, a genus of the hexandria monogynia class. The corolla consists of one bilabiate petal cut into six segments; and the capsule has three cells.

There are three species, none of them natives of Britain.

PONTEFRACT, a borough-town, eighteen miles south-west of York. It sends two members to parliament.

PONTIFICATE, is used for the state or dignity of a pontiff, or high priest; but more particularly, in modern writers, for the reign of a pope.

PONTON, or **PONTOON**, in war, denotes a little floating bridge made of boats and planks.

PONTUS, the ancient name of the countries situated on the south side of the Euxine sea, now a part of Asiatic Turkey.

POOL, in geography, a borough and port town of Dorsetshire, situated on a bay of the English channel, twenty miles east of Dorchester. It sends two members to parliament.

POOLOWAY, one of the Banda or nutmeg-islands in the Indian ocean: E. long. 128°, S. lat. 3° 30'.

POOP, the stern of a ship, or the highest, uppermost, and hinder part of the ship's hull.

POOR, in law, an appellation given to all persons who are in so low and mean a condition, as that they either are, or may become a burden to a parish.

POPAYAN, a province of South America, bounded by Terra-Firma, on the north; by New Granada, on the east; by Peru, on the south; and by the Pacific ocean, on the west; situated between 75 and 80 degrees west longitude, and between the equator and 5 degrees of north latitude, being four hundred miles long, and about three hundred broad.

POPE, the sovereign pontiff, or supreme head of the Romish church. The appellation of pope was anciently given to all Christian bishops; but about the latter end of the eleventh century, in the pontificate of Gregory VII. it was usurped by the bishop of Rome, whose peculiar title it has ever since continued.

POPE'S TERRITORIES, in Italy, are bounded by the Venetian territories, on the north; by the gulph of Venice, on the north-east; by Naples, on the south-east; by the Tuscan sea, on the south-west; and by the duchy of Tuscany, on the north-west, almost encompassing that duchy on the land side; being about two hundred and twenty miles long, and from twenty to one hundred and forty in breadth.

POPE, in ornithology. See **ALCA**.

POPLAR, in botany. See **POPULUS**.

POPLITÆUS, in anatomy. See **ANATOMY**, p. 268.

POPPY, in botany. See **PAPAVER**.

POPULAR, something that relates to the common people.

POPULUS, the poplar, in botany, a genus of the diœcia octandria class. The corolla of the male is turbinate, oblique, and entire; the stigma of the female is quadrid; and the capsule has two cells, containing many pappus seeds. There are five species, three of them natives of Britain, *viz.* the alba, or white poplar; the nigra, or black poplar; and the tremula, or trembling poplar, or asp.

PORCELAIN, a fine sort of earthen-ware, chiefly manufactured in China, and thence called china-ware. The most just idea we can form of the porcelain, or chin-

ware, is, that it is an half vitrified substance, or manufacture, in a middle state between the common baked earthen ware of our vulgar manufactures, and true glass. This is the essential and distinctive character of porcelain; and it is only by considering it in this light, that we are to hope of arriving at the perfect art of imitating it in Europe. This attempt is to be made on these principles in two different manners. The one by finding some appropriated matter, on which fire acts with more than ordinary strength, in the time of its passing from the common baked state of earthen ware into that of glass. The other is to compose a paste of two substances, reduced to a powder; the one of which shall be of force to resist a very violent fire, so as not to become vitrified in it; and the other a matter very easily vitrifiable. In the first case, the matter is to be taken out of the fire at the time when it is imperfectly vitrified; and in the other, the compound mass is to remain in the furnace, till the one substance which is the more easily vitrifiable is truly vitrified; and being then taken out, the whole will be what porcelain is, a substance in part vitrified, but not wholly so. The first method is that by which the European porcelain has been generally made, which though it may be very beautiful, yet it is always easy to distinguish even the finest of it from the china-ware: and the nature of the two substances appears evidently different: these owing all their beauty to their near approach to vitrification, are made to endure a long and violent fire, and are taken from it at a time when a little longer continuance should have made them perfect glass; on the contrary, the china-ware being made of a paste, part of which is made of a substance in itself scarce possible to be vitrified, bears the fire in a yet much more intense degree than ours, and is in no danger of running wholly into glass from it.

The two substances used by the Chinese, are well known by the names of petunse and kaolin; and on examining these, it appears very evident, that we have in Europe the very same substances, or at least substances of the very same nature, capable of being wrought into porcelain equally beautiful and fine.

PORCELAIN-SHELL. See *CYPRÆA*.

PORCUPINE, in zoology. See *HISTRIX*.

PORE, in anatomy, a little interstice or space between the parts of the skin, serving for perspiration.

PORELLA, in botany, a genus of mosses, the anthera of which is multilocular and foraminose. See *MOSS*.

PORIA, a genus of funguses, growing horizontally; but having its under side not formed into lamellæ, but full of little holes or pores.

There are a great many species of poria, among which is the agaric of the shops. See *AGARIC*, and *STYPTIC*.

PORPESSE, in ichthyology. See *DELPHINUS*.

PORPHYRY, in natural history, a kind of stone of a plain uniform mass, spotted with separate concretions, of great hardness, giving fire with steel, not fermenting with acids, and very slowly and difficultly calcining in a strong fire.

Porphyry is of several sorts; as, 1. The porphyry of the ancients, which is a most elegant mass of an extremely firm and compact structure, remarkably heavy, and of a fine strong purple, variegated more or less with pale, red, and white: its purple is of all degrees, from the cla-

re-colour to that of the violet; and its variegations are rarely disposed in veins, but spots, sometimes very small, and at others running into large blotches. It is less fine than many of the ordinary marbles; but it excels them all in hardness, and is capable of a most elegant polish. It is still found in immense strata in Egypt. 2. The hard red lead-coloured porphyry, variegated with black, white, green. This is a most beautiful and valuable substance. It has the hardness, and all the other characters of the oriental porphyry; and even greatly excels it in brightness, and in the beauty and variegation of its colours. It is found in great plenty in the island of Minorca; and is extremely worth importing, for it is greatly superior to all the Italian marbles. 3. The hard, pale-red porphyry, variegated with black, white, and green. This is of a pale flesh colour; often approaching to white. It is variegated in blotches from half an inch to an inch broad. It takes a high polish, and emulates all the qualities of the oriental porphyry. It is found in immense strata in Arabia Petrea, and in the Upper Egypt; and in separate nodules in Germany, England, and Ireland.

PORPHYRY SHELL. See *MUREX*.

PORRUM, in botany. See *ALLIUM*.

PORT GREVE, or **PORT GRAVE,** was formerly the principal magistrat of maritime towns. The chief magistrat of London was anciently called by this name, till Richard I. caused the city to be governed by two bailiffs; soon after which king John granted the city a mayor.

PORT-L'ORIENT, in geography, a fortress and port-town of Britany in France, at the mouth of the river Blavet: W long. 3° 15', N. lat. 47° 42'.

PORT-LOUIS, a port-town of Britany in France, situated in the bay of Bileay: W. long 3° 6', N. lat. 47° 42'.

PORT MAHON, a port-town of the island of Minorca, situated on a fine bay at the east end of the island, in E. long. 4° 6', N. lat. 39° 50'.

PORT ROYAL, the name of two monasteries of Cistercian nuns, in the diocese of Paris; the one near Chevreuse, at the distance of five leagues from Paris, called Port-Royal of the fields; and the other in Paris, in the suburbs of St. James.

The nuns of the former of these monasteries, proving refractory, were dispersed; when many ecclesiastics, and others who were of the same sentiments as these religious, retired to Port Royal, took apartments there, and printed many books: hence the name of Port-Royalists was given to all of their party, and their books were called books of Port-Royal: from hence we say the writers of Port Royal, *Messieurs de Port Royal*, and the translations and grammars of Port Royal.

PORT-ROYAL, in geography, a port-town, situated in the extremity of a long point of land, in the fourth-east part of the island of Jamaica: W. long. 77°, N. lat. 17° 30'.

PORT-ROYAL, an island on the coast of South-Carolina, which, with the neighbouring continent, forms one of the most commodious harbours in the British plantations: W. long. 80°, N. lat. 31° 45'.

PORTA, or **VENA PORTA,** in anatomy. See *ANATOMY*, p. 244.

PORTATE, or a **CROSS PORTATE,** in heraldry, a cross which does not stand upright, as crosses generally do, but lies across the escutcheon in bend, as if it were carried.

carried on a man's shoulders. See Plate CXLV. fig. 3.
PORTRENTRU, a city of Switzerland, in the bishoprick of Basle: E. long. 7° N. lat. $47^{\circ} 30'$.
PORTER, a kind of malt-liquor, which differs from ale and pale-beer in its being made with high-dried malt. See **BREWING**.
PORTRICO, in architecture, a kind of gallery on the ground, supported by columns, where people walk under covert.
PORTLAND, a peninsula in Dorsetshire, situated in the English channel, ten miles south of Dorchester, famous for producing the best free-stone.
PORTO BELLO, a port-town of America, situated on the narrowest part of the isthmus of Darien: W. long. 82° , N. lat. 10° .
PORTO-RICO, an island in the American ocean, one hundred and twenty miles long, and sixty broad, which produces sugar, rum, and ginger: situated between 64° and 68° of W. long. and in 8° of N. lat. It is subject to Spain. The capital is also called Porto Rico, and St. John's city.
PORTO SANTO, the least of the Madeira islands, eighteen miles in circumference: W. long. 16° , N. lat. 33° .
PORTRAIT, in painting, the representation of a person, and especially of a face, done from the life.
 In this sense we use the term portrait-painting, in contradistinction to history-painting, where a resemblance of person is usually disregarded. Portraits, when as large as the life, are usually painted in oil-colours; sometimes they are painted in miniature with water-colours, crayons, pastils, &c.
PORTSMOUTH, a borough and port town of Hampshire, situated on a fine bay of the English channel; it has one of the most secure, capacious, and best fortified harbours in England: W. long. $1^{\circ} 6'$, N. lat. $50^{\circ} 48'$. It sends two members to parliament.
PORTUGAL, the most westerly kingdom in Europe: it is about three hundred miles long, and one hundred broad; and is situated between 7° and 10° of W. long. and between 37° and 42° of N. lat. being bounded by Spain on the north and east, and by the Atlantic ocean on the south and west. This country is neither so hot nor so fruitful as Spain; it however produces plenty of grapes, olives, oranges and lemons.
PORTUGALLICA TERRA, *earth of Portugal*, the name of a fine alstringent bole, dug in great plenty in the northern parts of Portugal, and esteemed a remedy against poisons and venomous bites, and malignant fevers.
PORTULACA, in botany, a genus of the dodecandria monogynia class. The corolla consists of five petals, and the calix of two segments. There are six species, none of them natives of Britain.
POSE', in heraldry, denotes a lion, horse, or other beast standing still, with all his four feet on the ground.
POSITIVE, a term of relation, opposed to negative. It is also used in opposition to relative or arbitrary: thus we say, beauty is no positive thing, but depends on the different tastes of people.
POSITIVE DEGREE, in grammar, is the adjective in its simple signification, without any comparison. See **GRAMMAR**.
POSSE COMITATUS in law, signifies the power of the county, or the aid and assistance of all the knights,

gentlemen, yeomen, labourers, servants, apprentices, &c. and all others within the county that are above the age of fifteen, except women, ecclesiastical persons, and such as are decrepit and infirm.

This posse comitatus is to be raised where a riot is committed, a possession kept upon a forcible entry, or any force of rescue used, contrary to the king's writ, or in opposition to the execution of justice; and it is the duty of all sheriffs to assist justices of the peace in the suppression of riots, &c. and to raise the posse comitatus, or to charge any number of men for that purpose.

POSSESSION, in Scots law. See **LAW**, Tit. viii. 11.

POSSESSIVE, in grammar, a term applied to pronouns which denote the enjoyment or possession of any thing either in particular or in common: as *meus*, mine; and *tuus*, thine.

POSSESSORY action, in Scots law. See **LAW**, Tit. xxx. 18.

POSSIBILITY, in law, is defined to be any thing that is altogether uncertain, or what may or may not be.

POSSIBILITY also denotes a non-repugnance to existing, in any thing that does not any way exist.

POSSIBLE, is sometimes opposed to real existence: and is understood of a thing which, though it does not actually exist, yet may exist; as a new star.

POST, a courier or letter-carrier, or one who frequently changes horses, posted or placed on the road, for quicker dispatch. The word is also applied to the houses where such a person takes up and lays down his charge.

In England, posts were first established by act of parliament in the twelfth year of the reign of Charles II. which enabled the king to settle a post-office, and appoint a governor.

Penny Post, a post established for the benefit of London and the adjacent parts by which any letter or parcel not exceeding sixteen ounces weight, is speedily conveyed to and from all parts within ten miles of London.

POSTDAM or **POTSDAM** a town of Germany in the marquisate of Brandenburg, ten miles south-west of Berlin.

POSTHUMOUS, a child born after the death of his father, or taken out of the body of a dead mother: from whence it is frequently applied to the works of an author not published till after his decease.

POSTING, among merchants, the putting an account forward from one book to another, particularly from the journal or waste-book to the ledger. See **BOOK-KEEPING**.

POSTLIMINIUM, among the Romans, the return of one who had gone to sojourn elsewhere, or had been banished or taken by an enemy to his own country and state.

POSTULATE, in mathematics, &c. is described to be such an easy and self-evident supposition, as needs no explication or illustration to render it intelligible; as, that a right line may be drawn from one point to another.

POTAMOGETON, in botany, a genus of the tetrandria tetragynia class. It has no calix, nor stylus; but has four petals, and four seeds. There are 12 species, 10 of them natives of Britain.

POTANCE, in heraldry, a cross like that represented in Plate CXLV. fig. 4.

POT.

POT-ASH, the lixivious ashes of certain vegetables, used in the making of glass, soap, &c.

The method of making pot-ash is directed by Dr Shaw, as follows. Burn a quantity of billet-wood to grey ashes; and taking several pounds of these ashes, boil them in water, fo as to make a very strong lixivium, or lye. Let this lye be strained through a coarse linen cloth, to keep out any black parts of the half-burnt wood, that might happen to remain in the ashes: then evaporate this strained lye in an iron-pan over a quick fire almost to dryness: then taking out the matter remaining at the bottom, and putting it into an iron-crucible, set it in a strong fire till the matter is melted, and then immediately pour it out upon an iron-plate, where it soon cools, and appears in the form of a solid lump of pot-ash. Much after this manner is pot-ash made in the large way of business, for the service of the soap-boiler, glass-maker, fuller, &c. but according to the difference of the wood or combustible matter employed, with the manner of turning it, and conducting the process, different kinds of pot-ash are prepared.

POTATOE, in botany. See *CONVOLVULUS*, of which it is a species.

POTENT, or **POTENCE**, in heraldry, a term for a kind of a cross, whose ends all terminate like the head of a crutch. It is otherwise called the Jerusalem cross, and is represented in Plate CXLV. fig. 5.

POTENTIA, **Power**, that whereby a thing is capable either of acting, or being acted upon.

POTENTIAL, in the schools, is used to denote and distinguish a kind of qualities, which are supposed to exist in the body in potentia only, by which they are capable in some manner of affecting and impressing on us the ideas of such qualities, though not actually inherent in themselves; in which sense we say, potential heat, potential cold.

POTENTIAL, in medicine. Cauteries are distinguished into actual and potential. See *CAUTERY*.

POTENTIAL, in grammar, an epithet applied to one of the moods of verbs. The potential is the same in form with the subjunctive. See *GRAMMAR*.

POTENILLA, in botany, a genus of the icofandria polygynia class. The calix consists of ten segments, and the corolla of five petals; the seeds are round, naked, and fixed to the receptacle. There are 27 species, 8 of them natives of Britain.

This plant is said to possess in a great measure the virtues of the peruvian bark.

POTERIUM, in botany, a genus of the monœcia polyandria class. The calix of the male consists of five segments, that of the male has but one entire rough leaf. Neither of them have any corolla; the stamina of the male are from five to ten; and the styli of the female are from two to five; and the seed is single and oval. There are three species, one of which, viz. the sanguiforba, or burnet, is a native of Britain.

POTHOS, in botany a genus of the gynandria polyandria class. The spathe and spadix are roundish; it has no calix; the corolla has four petals; and the berry contains many seeds. There are seven species, none of them natives of Britain.

POTION, a liquid medicine, consisting of as much as can be drank at one draught.

POTOSI, a city of Peru in South America, situated at the bottom of a mountain of that name, in which is the richest silver-mine ever discovered: W. long. 67°, S. lat. 21°.

POTTERY, the manufacture of earthen ware, or the art of making earthen vessels.

The wheel and lathe are the chief, and almost the only instruments used in pottery, the first for large works, and the last for small. The potter's wheel consists principally in the nut; which is a beam or axis, whose foot or pivot plays perpendicularly on the tree-stone sole or bottom. From the four corners of this beam, which does not exceed two feet in height, arise four iron-bars, called the spokes of the wheel; which forming diagonal lines with the beam, descend, and are fastened at bottom to the edges of a strong wooden circle, four feet in diameter, perfectly like the fellows of a coach-wheel, except that it has neither axis nor radii, and is only joined to the beam which serves it as an axis by the iron-bars. The top of the nut is flat, of a circular figure, and a foot in diameter; and on this is laid the clay which is to be turned and fashioned. The wheel, thus disposed, is encompassed with four different pieces of wood fastened on a wooden frame. The hind-piece, which is that on which workman sits, is made a little inclining towards the wheel: on the fore-piece are placed the prepared earth: on the side-pieces he rests his feet; and these are made inclining, to give him more or less room. Having prepared the earth, the potter lays a round piece of it on the circular head of the nut; and sitting down turns the wheel with his feet, till it has got the proper velocity; then, wetting his hands with water, he presses his silt or his fingers-ends into the middle of the lump, and thus forms the cavity of the vessel, continuing to widen it from the middle; and thus turning the inside into form with one hand, while he proportions the outside with the other, the wheel constantly turning all the while, and he wetting his hands from time to time. When the vessel is too thick, he uses a flat piece of iron, somewhat sharp on the edge, to pare off what is redundant; and when it is finished, it is taken off from the circular head, by a wire passed underneath the vessel.

The potter's lathe is also a kind of wheel, but more simple and slight than the former. Its three chief members are an iron-beam or axis, three feet and a half high, and two feet and a half diameter, placed horizontally at the top of the beam, and serving to form the vessel upon; and another larger wooden wheel, all of a piece, three inches thick, and two or three feet broad, fastened to the same beam at the bottom, and parallel to the horizon. The beam or axis turns by a pivot at the bottom in an iron-stand. The workman gives the motion to the lathe with his feet, by pushing the great wheel alternately with each foot, still giving it a greater or lesser degree of motion, as his work requires. They work with the lathe, with the same instruments, and after the same manner as with the wheel. The mouldings are formed by holding a piece of wood or iron cut in the form of the moulding to the vessel, while the wheel is turning round; but the feet and handles are made by themselves, and set on with the hand; and if there be any sculpture in the work, it is usually done in wooden moulds, and stuck on piece by piece on the outside of the vessel.

POTTLE, an English measure containing two quarts.

POULTRY,

POULTRY, all kinds of domestic birds brought up in yards, as cocks, hens, capons, ducks, turkeys, &c.

POUND, a standing weight. See **MONEY**.

POUND also denotes a money of account; so called, because the ancient pound of silver weighed a pound troy. See **MONEY**.

POUNDAQE, a subsidy of 12 d. in the pound granted to the crown on all goods and merchandizes exported or imported; and if by aliens, one penny more.

POURRESTURE, in law, is a wrongful inclosure, or encroachment upon another person's property.

POURSUIVANT, or **PURSUIVANT**, in heraldry, the lowest order of officers at arms.

The poursuivants are properly attendants on the heralds, when they marshal public ceremonies. Of these in England, there were formerly many; but at present there are only four, *viz.* blue-mantle, rouge-crois, rouge dragon, and portcullis. In Scotland, there is only one king at arms, who is styled Lion; and has no less than six heralds, and as many pursuivants, and a great many messengers at arms, under him.

POURVEYANCE, or **PURVEYANCE**, in law, the providing corn, fuel, victual, &c. for the king's household; and hence the officer who did so was termed *pourveyor*.

POWDER, in pharmacy, a dry medicine well broken, either in a mortar by grinding, or by chemical operations.

POWER, the faculty of doing or suffering any thing.

Power therefore is two-fold, *viz.* considered as able to make, or able to receive any change; the former whereof may be called active power, and the latter passive power. See **METAPHYSICS**.

POWER, in mechanics. See **MECHANICS**.

POWER, in law, signifies, in general, a particular authority granted by any person to another to represent him, or act in his stead.

POWERS, in arithmetic and algebra, are nothing but the products arising from the continual multiplications of a number, or quantity, into itself. See **ALGEBRA**, p. 81. and **ARITHMETIC**, p. 420.

POX, or **SMALL POX**, in medicine. See **MEDICINE**, p. 75.

French Pox. See **MEDICINE**, p. 133.

PRACTICE, in arithmetic. See **ARITHMETIC**, p. 393.

PRAGMATIC SANCTION, in the civil law, is defined by Hottoman to be a rescript, or answer of the sovereign, delivered by advice of his council, to some college, order, or body of people, upon consulting him on some case of their community. The like answer given to any particular person, is called simply rescript. The term pragmatic sanction, is chiefly applied to a settlement of Charles VI. emperor of Germany, who, in the year 1722, having no sons, settled his hereditary dominions on his eldest daughter, the archduchess Maria Theresa. which was confirmed by the diet of the empire, and guaranteed by Great Britain, France, the States general, and most of the powers in Europe.

PRÆCEPTIO HEREDITATIS, in Scots law. See **LAW**, Tit. xxvii. 33.

PRAGUE, the capital of Bohemia, situated on the river Mulda, in E. long. 14° 20', N. lat. 50°. This is a strong fine city; and next to London, Paris, and Constantinople, the largest in Europe.

PRAMNION, in natural history, the name of a semi-pelagic gem.

This is a very singular stone, and of a very great con-

cealed beauty: our lapidaries, when they meet with it, call it by the name of the black agate. It is of an extremely close, compact, and firm texture, of a smooth and equal surface, and in shape very irregular; being sometimes round, sometimes oblong, and often flat; in size it seldom exceeds two inches. It appears, on a common inspection, to be of a fine deep black; but held up against the sun, or the light of a candle, it is an elegant red, clouded by a quantity of subtle black earth. We have it from the East-Indies,

PRASIUM, in botany, a genus of the didymia gymnospermia class. The berries are four, each containing one seed. There are two species, none of them natives of Britain.

PRATIQUE, or **PRATTIC**, in commerce, a negotiation, or communication, of commerce, which a merchant vessel obtains in the port it arrives in, and the countries it discovers; hence to obtain a *partique*, is to obtain a liberty to frequent a port, to go ashore, to buy and sell, &c.

PREAMBLE, in law, the beginning of an act of parliament, &c. which serves to open the intent of the act, and the mischiefs intended to be remedied by it.

PREBEND, the maintenance a prebendary receives out of the estate of a cathedral or collegiate church.

PREBENDARY, any ecclesiastic who enjoys a prebend.

PRECARIUM, in Scots law. See **LAW**, Tit. xx. 9.

PRECEDENCE, a place of honour to which a person is entitled. This is either of courtesy or of right. The former is that which is due to age, estate, &c. which is regulated by custom and civility; the latter is settled by authority, and, when broken in upon, gives an action at law.

PRECEDENT, in law, a case which has been determined, and which serves as a rule for all of the same nature.

PRECEPT, in law, a command in writing sent by a chief justice, justice of the peace, &c. for bringing a person, record, or other matter, before him.

PRECEPT OF CLARE CONSTAT, in Scots law. See **LAW**, Tit. xxvii. 28.

PRECEPT OF SEISIN, in Scots law. See **LAW**, Tit. x. 15.

PRECESSION, in astronomy. See **ASTRONOMY**, p. 562.

PRECIPITANT, in chemistry, is applied to any liquor, which, when poured on a solution, separates what is dissolved, and makes it precipitate, or fall to the bottom of the vessel. See **CHEMISTRY**.

The term precipitant is also used, in medicine, to denote any remedy that moderates the heat of the blood, by separating, as is supposed, any heterogeneous matter contained therein.

PRECIPITATE, in chemistry, a substance which, having been dissolved in a proper menstrum, is again separated from its solvent, and thrown down to the bottom of the vessel by pouring some other liquor upon it.

PRECIPITATION. See **CHEMISTRY**, p. 69, 107.

PRECOGNITION, in Scots law. See **LAW**, Tit. xxxiii.

PRECORDIA, in anatomy, a general name for the parts situated about the heart, in the fore-part of the thorax; as the diaphragm, pericardium, and even the heart itself, with the spleen, lungs, &c. See **ANATOMY**.

PREDECESSOR, properly signifies a person who has preceded or gone before another in the same office or employment; in which sense, it is distinguished from ancestor.

PREDESTINATION, in general, signifies a decree of God, whereby, from all eternity, he ordained such a concatenation of causes as must produce every event by a kind of necessity.

In this sense, the Turks are great predestinarians; and on this account are much more daring in battle, and willingly encounter greater dangers than they would otherwise do. See **MAHOMETANISM**.

Predestination among Christians, is used, in a more limited sense, for a judgment or decree of God, whereby he has resolved, from all eternity, to save a certain number of persons, from thence called *elect*; so that the rest of mankind being left in a state of impenitence, are said to be reprobated.

PREDICABLE, among logicians, denotes a general quality which may be predicated or asserted of several things: thus animal is predicable of mankind, beasts, birds, fishes, &c. See **LOGIC**.

PREDICAMENT, among logicians. See **LOGIC**.

PREDICATE, in logic, that part of a proposition which affirms or denies something of the subject. See **LOGIC**.

PREENING, in natural history, the action of birds dressing their feathers, to enable them to glide the more readily through the air, &c.

For this purpose they have two peculiar glands on their rump, which secrete an unctuous matter into a bag that is perforated, out of which the bird occasionally draws it with its bill.

PRE-EXISTENCE, the state of a thing actually in being before another.

PREFACE, something introductory to a book, to inform the reader of the design, method, &c. observed therein, and generally whatever is necessary to facilitate the understanding of a book.

PREFECT, in ancient Rome, one of the chief magistrates who governed in the absence of the kings, consuls, and emperors.

PREFECT of the pretorium, the leader of the pretorian bands destined for the emperor's guards, consisting, according to Dion, of 10,000 men. This officer, according to Suetonius, was instituted by Augustus, and usually taken from among the knights.

PREGNANCY, the state of a woman who has conceived, or is with child. See **MIDWIFERY**.

PREJUDICE does not mean a judgment merely as prior to another in respect of time, but as being passed before the things were duly considered and fully understood. Hence prejudice is sometimes called anticipation, and a preconceived opinion.

PRELATE, an ecclesiastic raised to some eminent and superior dignity in the church; as bishops, archbishops, patriarchs, &c.

PRELIMINARY, in general, denotes something to be examined and determined, before an affair can be treated of to the purpose.

PRELUDE, in music, is usually a flourish or irregular air, which a musician plays off-hand, to try if his instrument be in tune, and so lead him into the piece to be played.

PREMISSSES, in logic, an appellation given to the two first propositions of a syllogism. See **LOGIC**.

PRENANTHES, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is naked; and the pappus is simple. There are seven species, only one

of them, *viz.* the muralis, or ivy-leaved wild lettuce, is a native of Britain.

PREPOSITA NEGOTIIS DOMESTICIS, in Scots law. See **LAW** Tit. vi. 18.

PREPOSITION, in grammar. See **GRAMMAR**.

PREPUCE, in anatomy. See **ANATOMY**, p. 274.

PREROGATIVE of the king, that power which the king hath, not only over other persons, but over the ordinary course of the common law, in right of his crown.

Such as, that he may pardon a person condemned to die, that the king's person is subject to no man's suit, his possessions cannot be taken from him by any violence, his goods are subject to no tribute, nor distrainable, &c.

PRESAGE, in antiquity, denotes an augury, or sign of some future event; which was chiefly taken from the flight of birds, the entrails of victims, &c. See **AUGURY**, and **ARUSPICES**.

PRESBURG, the capital of Hungary, a large city on the north side of the Danube, fifty miles east of Vienna: E. long. 17° 30', N. lat. 48° 20'.

PRESBYTA, in optics, a person whose eyes being flat, can see distant objects distinctly, but those near confusedly; which defect of sight got this appellation, because old people are naturally subject to it.

Spectacles, or convex glasses, are the only remedy for this defect.

PRESBYTER, in the primitive Christian church, an elder, and of the second order of ecclesiastics; the other two being bishops and deacons.

PRESBYTERIANS, protestants, so called from their maintaining that the government of the church appointed in the New Testament was by presbyteries; that is, by ministers and ruling elders, associated for its government and discipline.

The presbyterians affirm, that there is no order in the church as established by Christ and his apostles superior to that of presbyters; that all ministers, being ambassadors of Christ, are equal by their commission; and that elder or presbyter, and bishop, are the same in name and office: for which they alledge, *Acts* xx. 28, &c.

The only difference between them and the church of England, relates to discipline and church-government. Their highest assembly is a synod, which may be provincial, national, or œcumenical; and they allow of appeals from inferior to superior assemblies; according to *Acts* x. 2, 6, 22, 23. The next assembly is composed of a number of ministers and elders, associated for governing the churches within certain bounds. This authority they found upon *Acts* xi. 30. *Acts* xv. 4, 6, &c. The lowest of their assemblies or presbyteries consists of the minister and elders of a congregation, who have power to cite before them any member, and to admonish, instruct, rebuke, and suspend him from the eucharist: They have also a deacon, whose office is to take care of the poor.

The ordination of their ministers is by prayer, fasting, and imposition of the hands of the presbytery. This is now the discipline of the church of Scotland.

PRESCIENCE, in theology, fore knowledge, or the knowledge which God has of events before they come to pass.

PRESCRIPTION, in Scots law. See **LAW**, Tit. xxvi. 1.

PRESENCE, a term of relation used in opposition to absence, and signifying the existence of a person in a certain place.

PRESENT TENSE, in grammar. See **GRAMMAR**.

PRE-

PRESENTATION, in Scots law. See **LAW**, Tit. v. 7.
PRESS, in the mechanic arts, a machine of wood, or iron, serving to squeeze any body very close, generally by means of a screw. See **MECHANICS**.

PRESIER JOHN, or **JEAN**, an appellation given to the king of Abyssinia or Ethiopia.

This name is altogether unknown in Ethiopia, where he is called the grand Negus.

PRESTO, in the Italian music, intimates to perform very quick as *prestissimo* does extremely so.

PRESTON, a borough-town, twenty miles south of Lancaster, which sends two members to parliament.

PRESUMPTION, in Scots law. See **LAW**, Tit. xxxi. 18.

PRETERITE TENSE, in grammar. See **GRAMMAR**.

PRETEXT, a colour or motive, whether real or feigned, for doing something.

Toga PRETEXTA, among the ancient Romans, a long white gown, with a border of purple round the edges, and worn by children of quality till the age of puberty, viz. by the boys till seventeen, when they changed it for the toga virilis; and by the girls till marriage.

PRETOR, a magistratus among the ancient Romans, not unlike our lord chief justices, or lord chancellor, or both in one: as being vested with the power of distributing justice among the citizens. At first there was only one pretor; but afterwards another being created, the first or chief one had the title of pretor urbanus, or the city-pretor; the other was called peregrinus, as being judge in all matters relating to foreigners. But besides these, there were afterwards created many provincial pretors; who were not only judges, but also assisted the consuls in the government of the provinces, and even were invested with the government of provinces themselves.

PRETORIAN GUARDS, in Roman antiquity, were the emperor's guards, who at length were increased to ten thousand: they had this denomination, according to some, from their being stationed at a place in the palace called prætorium: their commander was titled præfectus prætorii. See **PREFECT**.

PRETORIUM, among the Romans, denoted the hall or court wherein the pretor lived, and wherein he administered justice.

PREVENTION in *Jurisdiction*, in Scots law. See **LAW**, Tit. ii. 5.

TRIAPISM, in medicine, a continual and painful erection of the penis.

TRIAPUS in medicine, denotes the genital parts in men. It also denotes, in antiquity, a fabulous deity, particularly adored at Lampsacus, the place of his birth, who was revered very much for the extraordinary size of his parts.

PRIEST, a person set apart for the performing of sacrifices and other offices of religion.

PRIEST, in the Christian church, is a person invested with holy orders, in virtue whereof he has a power to preach, pray, administer the sacraments, &c.

PRIMÆVIÆ, among physicians, denote the whole alimentary duct; including the oesophagus, stomach, and intestines, with their appendages.

PRIMAGE, in commerce, a small duty at the water side, usually about twelve pence per tun, or six pence a bale, due to the master and mariners of a ship.

PRIMATE, in church-poly, an archbishop, who is invested with a jurisdiction over other bishops.

PRIME, an appellation given to whatever is first in order, degree, or dignity, among several things of the same or like kind; thus we say the prime minister, prime cost, &c.

PRIMIPILUS, in antiquity, the centurion of the first cohort of a legion, who had charge of the Roman eagle.

PRIMITIVE, the first fruits gathered of the earth, whereof the ancients made presents to the gods.

PRIMITIVE, in grammar, is a root or original word in a language, in contradistinction to derivative: thus, *God* is a primitive, *godly* a derivative, and *god-like* a compound.

PRIMULA, in botany, a genus of the pentandria monogynia class. The tube of the corolla is cylindrical, with an open mouth. There are eight species, three of them natives of Britain. viz. the vulgaris, or common primrose; the veris, or cows-lips; and the farinosa, or birds-eye.

PRINCE, in polity, a person invested with the supreme command of a state, independent of any other.

Prince also denotes a person who is a sovereign in his own territories, yet holds of some other as his superior; such are the princes of Germany.

PRINCIPAL, the chief and most necessary part of a thing.

PRINCIPATE, a province of the kingdom of Naples, situated on the Mediterranean, between the provinces of Lavoro and Calabria and divided into the Hither and Further Principate, with respect to the city of Naples.

PRINCIPLE, in general, is used for the cause, source, or origin of any thing.

PRINCIPLE, is also sometimes used in a synonymous sense with axiom or maxim.

PRINOS, in botany, a genus of the hexandria monogynia class. The calix consists of six segments, and the corolla of one rotated petal; and the berry contains six seeds. There are two species, both natives of America.

PRINT, the impression taken from a copperplate. See *Rolling-press* **PRINTING**.

PRINTER, a person who composes and takes impressions from moveable characters ranged in order, or front plates engraven, by means of ink, and a press, or from blocks of wood cut in flowers, &c. and taken off in various colours on calicoes, linens, silks, &c.

The most curious of these arts, and that which deserves the most particular explication, is the first; for to the printers of books are chiefly owing our deliverance from ignorance and error, the progress of learning, the revival of the sciences, and numberless improvements in arts, which, without this noble invention, would have been either lost to mankind, or confined to the knowledge of a few. The first printers were Guttenberg, Fust, Schoeffer, Mentel, and Koller; and the first who practised this art in England was Fred. Corseilles, who brought it over from Harlem, in the reign of king Henry VI. The great printers famous for the correctness and elegance of their works, were Aldus, and Paulus Manutius; the two Badii; William and Frederic Morel; Oporin; Frobenius; Robert, Henry, and Charles Stephens; Gryphus, Turnebus, Torres, Commelin, Plantin, Raphelengius, Vascosan, Bleau, Crispin, and the two Elzevirs; and among these, the learned printers were the Manutii, the Stephenses, the Bodii, Turnebus, Morel, &c. Plantin had the title of architypographus, or arch-printer, given him.

him by the king of Spain in consideration of his printing the polyglot of Antwerp. The printers of Germany, &c. generally cast their own letter, and sell their own books. There are in many places ranked among the members of universities, and entitled to the privilege of students. In England, they are esteemed a part of the company of stationers and booksellers.

PRINTING, the art of taking impressions from characters or figures, moveable or immovable, on paper, linen, silk, &c. There are three kinds of printing; the one from moveable letters, for books; another from copper-plates, for pictures; and the last from blocks, in which the representation of birds, flowers, &c. are cut, for printing calicoes, linens, &c. the first call common-press printing, the second rolling-press printing, and the last calico, &c. printing. The principal difference between the three consists in this, that the first is cast in relief, in distinct pieces; the second engraven in creux; and the third cut in relief, and generally stamped, by placing the block upon the materials to be printed, and striking upon the back of it.

Progress of PRINTING. Who the first inventors of the European method of printing books were, in what city and what year it was set on foot, are questions long disputed among the learned. In effect, as the Grecian cities contended for the birth of Homer, so do the German cities for that of printing. Mentz, Haerlem, and Strasburg, are the warmest on this point of honour. John Guttenburg, and John Fust of Mentz; John Mentel of Strasburg, and L. John Koster of Haerlem; are the persons to whom this honour is severally ascribed, by their respective countrymen; and they have all their advocates among the learned. However, their first essays were made on wooden blocks, after the Chinese manner. The book at Haerlem, the vocabulary called Catholicon, and the pieces in the Bodleian library, and that of Bennet-college, are all performed in this way; and the impression appears to have been only given on one side of the leaves, after which the two blank sides were pasted together. But they soon found the inconveniences of this method; and therefore bethought themselves of an improvement; which was by making single letters distinct from one another; and these being first done in wood, gave room for a second improvement, which was the making them of metal; and, in order to that, forming moulds, matrices, &c. for casting them.

From this ingenious contrivance we ought to date the origin of the present art of printing, contradistinguished from the method practised by the Chinese. And of this Schoeffer, or Scheffer, first servant, and afterwards partner and son-in-law of Fust, at Mentz, abovementioned, is pretty generally allowed to be the inventor, so that he may properly be reckoned the first printer, and the Bible which was printed with moveable letters in 1450, the first printed book; the next was Augustinus de civitate Dei, then Tully's offices, printed about the year 1461. In these books they left the places of the initial letters blank, and gave them to the illuminers to have them ornamented and painted in gold and azure, in order to render the work more beautiful, and, as some think, to make their books pass for manuscripts.

Some authors tell us, that Fust carrying a parcel of bibles with him to Paris, and offering them to sale as

manuscripts; the French, upon considering the number of books, and their exact conformity to each other even to a point, and that it was impossible for the best book-writers to be so exact, concluded there was witchcraft in the case, and, by their actually indicting him as a conjurer, or threatening to do so, extorted from him the secret; and hence the origin of the popular story of Dr. Faustus.

From Mentz, the art of printing soon spread itself throughout a good part of Europe: Haerlem and Strasburg had it very early; which, as the current of authors represent it, occasioned their pretending to the honour of the invention. From Haerlem it passed to Rome in 1467; and into England in 1468, by means of Tho. Bouchier, archbishop of Canterbury, who sent W. Turner master of the robes, and W. Caxton merchant, to Haerlem to learn the art. These privately prevailing with Corseilles, an under-workman, to come over, a press was set up at Oxford and an edition of Rufinus on the creed was printed the same year in octavo. From Oxford, Caxton brought it to London about the year 1470, and the same year it was carried to Paris. Hitherto there had been nothing printed but in Latin, and the vulgar tongues; and this first in Roman characters, then in Gothic, and at last in Italic: but in 1480, the Italians cast a set of Greek types; and they have also the honour of the first Hebrew editions, which were printed about the same time with the Greek. Towards the end of the sixteenth century there appeared various editions of books in Syriac, Arabic, Persian, Armenian, Coptic or Egyptian characters: some to gratify the curiosity of the learned, and others for the use of the Christians of the Levant. Out of Europe, the art of printing has been carried into the three other parts of the world: for Asia, we see impressions of books at Goa, and in the Philippines; at Morocco, for Africa; at Mexico, Lima, Philadelphia, New York, Boston, &c. for America. The Turks, indeed, rigorously prohibit printing throughout their empire, as imagining that the too frequent communication with books might occasion some change in their religion and government; yet the Jews have several editions of their books printed at Thessalonica, and even at Constantinople.

Method of PRINTING. The workmen employed in the art of printing are of two kinds: compositors, who range and dispose the letters into words, lines, pages, &c. according to the copy delivered them by the author; and pressmen who apply ink upon the same, and take off the impression. The types being cast, the compositor distributes each kind by itself among the divisions of two wooden frames, an upper and an under one, called cases; each of which is divided into little cells or boxes. Those of the upper case are in number ninety-eight: these are all of the same size; and in them are disposed the capitals, small capitals, accented letters, figures, &c. the capitals being placed in alphabetical order. In the cells of the lower case, which are fifty-four, are placed the small letters, with the points, spaces, &c. The boxes are here of different sizes, the largest being for the letters most used; and these boxes are not in alphabetical order, but the cells which contain the letter oftenest wanted are nearest the compositor's hand. Each case is placed a little aslope, that the compositor may the more easily reach the upper boxes. The instrument in which the letter are set is called a composing-stick, (*ibid.* n° 2) which consists

confists of a long and narrow plate of brafs, or iron, &c. *cc*; on the right-side of which arises a ledge *bb*, which runs the whole length of the plate, and serves to sustain the letters, the sides of which are to rest against it: a-long this ledge is a row of holes, which serve for introducing the screw *f*, in order to lengthen or shorten the extent of the line, by moving the sliders *e d* farther from or nearer to the shorter ledge at the end *a*. Where marginal notes are required in a work, the two sliding-pieces *e d* are opened to a proper distance from each other, in such a manner as that while the distance between *d* and *e* forms the length of the line in the text, the distance between the two sliding-pieces forms the length of the lines for the notes on the side of the page. Before the compositor proceeds to compose, he puts a rule, or thin slip of brafs-plate, cut to the length of the line, and of the same height as the letter, in the composing-stick, against the ledge, for the letter to bear against. Things thus prepared, the compositor having the copy lying before him, and his stick in his left-hand, his thumb being over the slider *d*; with the right, he takes up the letters, spaces, &c. one by one, and places them against the rule, while he supports them with his left thumb by pressing them to the end of the slider *d*, the other hand being constantly employed in setting in other letters: the whole being performed with a degree of expedition and address not easy to be imagined.

A little being thus composed, if it end with a word or syllable, and exactly fill the measure, there needs no further care; otherwise, more spaces are to be put in, or else the distances lessened between the several words, in order to make the measure quite full, so that every line may end even. The spaces here used are pieces of metal exactly shaped like the shanks of the letters: these are of various thicknesses, and serve to support the letters, and to preserve a proper distance between the words; but not reaching so high as the letters, they make no impression when the work is printed. The first line being thus finished, the compositor proceeds to the next; in order to which he moves the brafs-rule from behind the former, and places it before it, and thus composes another line against it after the same manner as before; going on thus till his stick is full, when he empties all the lines contained in it into the galley.

The compositor then fills and empties his composing-stick as before, till a complete page be formed; when he ties it up with a cord or pack-thread, and setting it by, proceeds to the next, till the number of pages to be contained in a sheet is completed; which done, he carries them to the imposing-stone, there to be ranged in order, and fastened together in a frame called a chase, and this is termed imposing. The chase is a rectangular iron-frame, of different dimensions, according to the size of the paper to be printed, having two cross-pieces of the same metal, called a long and short cross, mortised at each end so as to be taken out occasionally. By the different situation of these crosses the chase is fitted for different volumes: for quartos and octavos, one traverses the middle lengthwise, the other broadwise, so as to intersect each other in the centre: for twelves and twenty fours, the short cross is shifted nearer to one end of the chase: for folios, the long cross is left entirely out, and the short one left in the middle; and for broad-sides, both crosses are set

aside. To dress the chase, or range and fix the pages therein, the compositor makes use of a set of furniture, consisting of slips of wood of different dimensions, and about half an inch high, that they may be lower than the letters: some of these are placed at the top of the pages, and called head-sticks; others between them, to form the inner margin; others on the sides of the crosses, to form the outer margin, where the paper is to be doubled; and others in the form of wedges to the sides and bottom of the pages. Thus all the pages being placed at their proper distances, and secured from being injured by the chase and furniture placed about them, they are all untied, and fastened together by driving small pieces of wood called quoins, cut in the wedge-form, up between the flanting side of the foot and side sticks and the chase, by means of a piece of hard wood and a mallet; and all being thus bound fast together, so that none of the letters will fall out, it is ready to be committed to the pressman. In this condition the work is called a form; and as there are two of these forms required for every sheet, when both sides are to be printed, it is necessary the distances between the pages in each form should be placed with such exactness, that the impression of the pages in one form shall fall exactly on the back of the pages of the other, which is called register.

As it is impossible but that there must be some mistakes in the work, either through the oversight of the compositor, or by the casual transposition of letters in the cases; a sheet is printed off, which is called a proof, and given to the corrector; who reading it over, and rectifying it by the copy, by making the alterations in the margin, it is delivered back to the compositor to be corrected.

The compositor then unlocking the form upon the correcting stone, by loosening the quoins or wedges which bound the letters together, rectifies the mistakes by picking out the faulty or wrong letters with a slender sharp-pointed steel-bodkin, and puts others into their places. After this another proof is made, sent to the author, and corrected as before; and lastly, there is another proof, called a revise, which is made in order to see whether all the mistakes marked in the last proof are corrected.

The pressman's business is to work off the forms thus prepared and corrected by the compositor; in doing which there are four things required, paper, ink, balls, and a press. To prepare the paper for use, it is to be first wetted by dipping several sheets together in water: these are afterwards laid in a heap over each other; and to make them take the water equally, they are all pressed close down with a weight at the top. The ink is made of oil and lamp-black; for the manner of preparing which, see *Printing Ink*. The balls, by which the ink is applied on the forms, are a kind of wooden funnels with handles, the cavities of which are filled with wool or hair, as is also a piece of alum-leather or pelt nailed over the cavity, and made extremely soft by soaking in urine, and by being well rubbed. One of these pressmen takes in each hand; and applying one of them to the ink-block, daubs and works them together to distribute the ink equally. and then blackens the form which is placed on the press, by beating with the balls upon the face of the letter.

The printing-press represented in Plate CXLVII. fig. 1.
6 N . † n^o 2.

n^o 1. is a very curious, though complex machine. The body consists of two strong checks, *a a*, placed perpendicularly, and joined together by four cross-pieces; the cap *b*; the head *c*, which is moveable, being partly sustained by two iron-pins, or long bolts, that pass the cap; the shelves *d d*, which serve to keep steady a part called the hofe; and the winter *e*, which bears the carriage, and sustains the effort of the prefs beneath. The spindle *f* is an upright piece of iron pointed with steel, having a male-screw which goes into the female one in the head about four inches. Through the eye *g* of this spindle is fastened the bar *k*, by which the pressman makes the impression. Part of the spindle is inclosed in a square wooden frame called the hofe *h*, and its point works into a brass-pan supplied with oil, which is fixed to an iron-plate let into the top of the platten. At each corner of the hofe, there is an iron-hook fastened with pack-thread to those at each end of the platten *i*, in such a manner as to keep it perfectly level. The carriage *l l* is placed a foot below the platten, having its fore-part supported by a prop called the fore-stay, while the other rests on the winter. On this carriage, which sustains the plank, are nailed two long iron-bars or ribs, and on the plank are nailed short pieces of iron or steel called cramp-irons, equally tempered with the ribs, and which slide upon them when the plank is turned in or out. Under the carriage is fixed a long piece of iron called the spit, with a double wheel in the middle, round which leather-girths are fastened, nailed to each end of the plank; and to the outside of the spit is fixed a rounce *m*, or handle to turn round the wheel. Upon the plank is a square frame or coffin, in which is inclosed a polished stone on which the form *n* is laid; at the end of the coffin are three frames, *viz.* the two tympan and frisket: the tympan *o* is square, and made of three slips of very thin wood, and at the top a piece of iron still thinner; that called the outer tympan is fastened with hinges to the coffin: they are both covered with parchment; and between the two are placed blankets, which are necessary to take off the impression of the letters upon the paper. The frisket *p* is a square frame of thin iron, fastened with hinges to the tympan; it is covered with paper cut in the necessary places, that the sheet, which is put between the frisket and the great or outward tympan, may receive the ink, and that nothing may hurt the margins. To regulate the margins, a sheet of paper is fastened upon this tympan, which is called the tympan-sheet; and on each side is fixed an iron point, which makes two holes in the sheet, which is to be placed on the same points, when the impression is to be made on the other side. In preparing the prefs for working, the parchment which covers the outer tympan is wetted till it is very soft, in order to render the impression more equable; the blankets are then put in, and secured from slipping by the inner tympan: then while one pressman is beating the letter with the balls *q*, covered with ink taken from the ink-block, the other person places a sheet of white paper on the tympan-sheet, turns down the frisket upon it to keep the paper clean and prevent its slipping; then bringing the tympan upon the form, and turning the rounce, he brings the form with the stone, &c. weighing about 300 pounds weight, under the platten; pulls with the bar, by which means the platten presses the blankets and

paper close upon the letter, whereby half the form is printed; then raising the bar, he draws the form still forward, gives a second pull; and letting go the bar, turns back the form, takes up the tympan and frisket, takes out the printed sheet, and lays on a fresh one; and this is repeated till he has taken off the impression upon the full number of sheets the edition is to consist of. One side of the sheet being thus printed, the form for the other is laid upon the prefs, and worked off in the same manner.

Chinese PRINTING, is performed from wooden planks or blocks, cut like those used in printing of callico, paper, cards, &c.

Rolling-prefs PRINTING, is employed in taking off prints or impressions from copper-plates engraven, etched, or scraped as in mezzotintos. See ENGRAVING.

This art is said to have been as ancient as the year 1540, and to owe its origin to Finiguerra, a Florentine goldsmith, who pouring some melted brimstone on an engraven plate, found the exact impression of the engraving left in the cold brimstone, marked with black taken out of the strokes by the liquid sulphur: upon this he attempted to do the same on silver-plates with wet paper, by rolling it smoothly with a roller; and this succeeded: but this art was not used in England till the reign of king James I. when it was brought from Antwerp by Speed. The form of the rolling-prefs, the composition of the ink used therein, and the manner of applying both in taking off prints, are as follow.

The rolling-prefs AL (Plate CXLVII. fig. 2.) may be divided into two parts, the body and carriage: the body consists of two wooden cheeks PP placed perpendicularly on a stand or foot LM, which sustains the whole prefs. From the foot likewise are four other perpendicular pieces *e, e, e, e*, joined by other cross or horizontal ones *d, d, d*, which serve to sustain a smooth even plank or table HIK, about four feet and a half long, two feet and a half broad, and an inch and a half thick. Into the cheeks go two wooden cylinders or rollers, DE, FG, about six inches in diameter, borne up at each end by the cheeks, whose ends, which are lessened to about two inches diameter, and called trunnions, turn in the cheeks about two pieces of wood in form of half-moons, lined with polished iron to facilitate the motion: Lastly, to one of the trunnions of the upper roller is fastened a cross, consisting of two levers A.B, or pieces of wood, traversing each other, the arms of which cross serve instead of the bar or handle of the letter-prefs, by turning the upper roller, and when the plank is between the two rollers, giving the same motion to the under one, by drawing the plank forward and backward.

The ink used for copper-plates, is a composition made of the stones of peaches and apricots, the bones of sheep, and ivory, all well burnt, and called Frankfort black, mixt with nut-oil that has been well boiled, and ground together on a marble, after the same manner as painters do their colours.

The method of printing from copper-plates is as follows. They take a small quantity of this ink on a rubber made of linen-rags, strongly bound about each other, and therewith smear the whole face of the plate as it lies on a grate over a charcoal-fire. The plate being sufficiently inked, they first wipe it over with a foul rag, then with the

the palm of their left hand, and then with that of the right; and to dry the hand and forward the wiping, they rub it from time to time in whiting. In wiping the plate perfectly clean, yet without taking the ink out of the engraving, the address of the workman consists. The plate thus prepared, is laid on the plank of the press; over the plate is laid the paper, first well moistened, to receive the impression, and over the paper two or three folds of flannel. Things thus disposed, the arms of the press are pulled and by that means the plate with its furniture passed through between the rollers, which pinching very strongly, yet equally, presses the moistened paper into the strokes of the engraving, whence it licks out the ink.

PRIOR, the superior of a convent of monks, or the next under the abbot. See **ABBOT**.

PRISCILLIANISTS, in church-history, Christian heretics, so called from their leader Priscillian, a Spaniard by birth, and bishop of Avila. He is said to have practised magic, and to have maintained the principal errors of the Manichees; but his peculiar tenet was, that it is lawful to make false oaths, in order to support one's cause and interest.

PRISM, an oblong solid, contained under more than four planes whose bases are equal, parallel, and alike situated.

PRIVATEERS, in maritime affairs, a kind of private ships of war, fitted out by private persons at their own expence; who have leave granted them to keep what they can take from the enemy, allowing the admiral his share. See **LETTER of Marque**.

PRIVATION, in general, denotes the absence or want of something; in which sense, darkness is only a privation of light.

PRIVATIVE, in grammar, a particle which, when prefixed to a word, changes it into a contrary sense. See **GRAMMAR**.

PRIVET, in botany. See **LIGUSTRUM**.

PRIVILEGE, in law, some peculiar benefit granted to certain persons or places, contrary to the usual course of the law.

Privileges are said to be personal or real. Personal privileges are such as are extended to peers, ambassadors, members of parliament and of the convocation, and their menial servants, &c. See **PEER**, **EMBASSADOR**, **PARLIAMENT**, &c.

PRIVILEGED DEBTS, in Scots law. See **LAW**, Tit. xxviii. 19.

PRIVY-COUNCIL See **Privy-COUNCIL**.

PRIVY SEAL. See **SEAL**.

PRIZE, in maritime affairs, a vessel taken at sea from the enemies of a state, or from pirates; and that either by a man of war, a privateer, &c. having a commission for that purpose.

PROBABILITY, is nothing but the appearance of the agreement or disagreement of two ideas by the intervention of proofs whose connection is not constant and immutable, or is not perceived to be so; but is, or appears for the most part to be so; and is enough to induce the mind to judge the proposition to be true or false, rather than the contrary. See **LOGIC** and **METAPHYSICS**.

PROBATE of a will or testament, in law, is the exhibiting and proving of last wills and testaments before the

ecclesiastical judge delegated by the bishop who is ordinary of the place where the party died.

PROBATION, in the universities, is the examination and trial of a student who is about to take his degrees.

PROBATION, in Scots law. See **LAW**, Tit. xxxi. 1, *et seq.*

PROBATIONER, in the church of Scotland, a student in divinity, who bringing a certificate from a professor in an university of his good morals, and his having performed his exercises to approbation, is admitted to undergo several trials.

PROBE, a surgeon's instrument for examining the circumstances of wounds, ulcers, and other cavities, searching for stones in the bladder, &c.

PROBLEM, in logic, a proposition that neither appears absolutely true nor false; and, consequently, may be asserted either in the affirmative or negative.

PROBLEM, in geometry, is a proposition, wherein some operation or construction is required; as to divide a line or angle, erect or let fall perpendiculars, &c. See **GEOMETRY**.

PROBOSCIS, in natural history, is the trunk or snout of an elephant, and some other animals and insects.

PROCATARTIC CAUSE, in medicine, the pre-existing, or pre-disposing cause or occasion of a disease.

PROCELEUSMATICUS, in the ancient poetry, a foot consisting of four short syllables, or two pyrrhichicuses; as, *hominibus*.

PROCELLARIA, in ornithology, a genus of birds, belonging to the order of anseres. The beak is somewhat compressed, and without teeth; the mandibles are equal, the superior one being crooked at the point; the feet are palmated, the hind-claw being sessil, without any toe. There are six species, principally distinguished by their colour.

PROCESS, in law, denotes the proceedings in any cause, real or personal, civil or criminal, from the original writ to the end thereof.

PROCESS, in chemistry, the whole course of an experiment or series of operations, tending to produce something new.

PROCESS, in anatomy, denotes any protuberance or eminence in a bone.

PROCESSION, a ceremony in the Romish church, consisting of a formal march of the clergy and people, putting up prayers, &c. and in this manner visiting some church, &c. They have also processions of the host or sacrament. See **HOST**.

PROCLAMATION, a public notice given of any thing of which the king thinks proper to advertise his subjects.

Proclamations are a branch of the king's prerogative; and no person can make them without the king's authority, except mayors of towns, &c. by custom of privilege. Proclamations which require the people to do or not to do certain things, have the force of laws; but then they are supposed to be consistent with the laws already in being, otherwise they are superseded.

PROCONSUL, a Roman magistrate, sent to govern a province with consular authority.

PROCREATION, the begetting and bringing forth children. See **GENERATION** and **MIDWIFERY**.

PROCTOR, a person commissioned to manage another person's cause in any court of the civil or ecclesiastical law.

PROCURATION, an act or instrument by which a person

is impowered to treat, transact, receive, &c. in another person's name.

TROCURATOR, a person who has a charge committed to him to act for another.

PROCYON, in astronomy. See **ASTRONOMY**, p. 487.

PRODUCT, in arithmetic. See **ARITHMETIC**, p. 371.

PROFANATION, the acting disrespectfully to sacred things.

PROFANE, a term used in opposition to holy; and, in general, is applied to all persons who have not the sacred character, and to things which do not belong to the service of religion.

PROFESSION, among the Romanists, denotes the entering into a religious order, whereby a person offers himself to God by a vow of inviolably observing obedience, chastity, and poverty.

PROFESSOR, in the universities, a person who teaches, or reads public lectures in some art or science from a chair for the purpose.

PROFILE, in architecture, the draught of a building, fortification, &c. wherein are expressed the several heights, widths, and thickneses, such as they would appear were the building cut down perpendicularly from the roof to the foundation.

TROFLUVIUM, in medicine, denotes a flux, or liquid evacuation, of any thing.

PROGNOSTICS, among physicians, signifies a judgment concerning the event of a disease; as, whether it shall end in life or death, be short or long, mild or malignant, &c.

PROGRESSION, in general denotes a regular advancing, or going forward in the same course and manner. See **ARITHMETIC**, **ALGEBRA**, and **GEOMETRY**.

PROJECTION, in mechanics, the act of communicating motion to a body, from thence called projectile. See **MECHANICS**.

PROJECTURE, in architecture, the out jetting, prominence, or embossing, which the mouldings and other members have beyond the naked wall, column, &c. See **ARCHITECTURE**.

PROLAPSUS, in surgery, a prolapsion, or falling out of any part of the body from its natural situation; thus we say prolapsus intestini, a prolapsion of the intestine, &c. See **SURGERY**.

PROLATE, in geometry, an epithet applied to a spheroid produced by the revolution of a semi-ellipsis about its larger diameter.

PROLEGOMENA, certain preparatory observations or discourses prefixed to a book, &c. containing something necessary for the reader to be apprised of, to enable him the better to understand the book, or to enter deeper into the science, &c.

PROLEPSIS, a figure in rhetoric, by which we anticipate or prevent what might be objected by the adversary.

PROLEPTIC, an epithet applied to a periodical disease which anticipates, or whose paroxysm returns sooner and sooner every time, as is frequently the case in agues.

PROLIFIC, something that has the qualities necessary for generating.

PROLIXITY, in discourse, the fault of entering into too minute a detail, of being too long, precise, and circumstantial, even to a degree of tediousness.

PROLOGUE, in dramatic poetry, a discourse addressed to the audience before the drama or play begins. The

original intention was to advertise the audience of the subject of the piece, and to prepare them to enter more easily into the action, and sometimes to make an apology for the poet.

PROMETHEUS, in the ancient astronomy, the name of the constellation now called Hercules. See **ASTRONOMY**, p. 487.

PROMISE, in law, is when upon any valuable consideration one binds himself by word of mouth to another to perform a thing agreed on.

PROMONTORY, in geography, a high point of land or rock projecting out into the sea; the extremity of which towards the sea, is called a cape, or headland.

PROMULGATED, something published or proclaimed, and generally applied to a law, to denote the publishing or proclaiming to the people.

PRONATION. See **ANATOMY**, p. 179.

PRONATORS, in anatomy. See **ANATOMY**, p. 198.

PRONOUN, in grammar, a declinable part of speech, which being put instead of a noun, points out some person or thing. See **GRAMMAR**.

PRONUNCIATION, in grammar, the manner of articulating or sounding the words of a language. See **GRAMMAR**.

PROOF, in law, &c. denotes the mediums or arguments used to evince the truth of any thing.

PROPAGATION, the act of multiplying the kind. See **GENERATION**.

PROPER, something naturally and essentially belonging to any thing.

PROPERTY, in a general sense, that which constitutes or denominates a thing proper; or it is a particular virtue or quality which nature has bestowed on some things exclusive of all others: thus colour is a property of light; extension, figure, divisibility, and impenetrability, are properties of body.

PROPERTY, in law, is described to be the highest right a person has, or can have, to any thing.

PROPHECY, a prediction made by divine inspiration.

PROPHET, in general, a person who foretells future events; but is particularly applied to such inspired persons among the Jews as were commissioned by God to declare his will and purposes to that people. Among the canonical books of the Old Testament, we have the writings of sixteen prophets, four of which are denominated the greater prophets *viz.* Isaiah, Jeremiah, Ezekiel, and Daniel, so called from the length or extent of their writings, which exceed those of the others, *viz.* Hosea, Joel, Amos, Obadiah, Jonah, Micah, Nahum, Habakkuk, Zephaniah, Haggai, Zechariah, and Malachi, who are called the lesser prophets from the shortness of their writings. The Jews do not place Daniel among the prophets, because, they say, he lived the life of a courtier rather than that of a prophet.

PROPIATION, in theology, a sacrifice offered to God to assuage his wrath, and render him propitious. Among the Jews there were both ordinary and public sacrifices, as holocausts, &c. offered by way of thanksgiving; and extraordinary ones, offered by particular persons guilty of any crime, by way of propitiation. The Romish church believe the mass to be a sacrifice of propitiation for the living and the dead. The reformed churches allow

of no propitiation but that one offered by Jesus Christ on the cross.

PROPOLIS, the name of a certain substance more glutinous and tenacious than wax, with which the bees stop up all the holes or cracks in the sides of their hives. See **APIS**.

PROPONTIS, or *Sea of MARMORA*, divides Europe from Asia; having the Bosphorus on the north-east, by which it has a communication with the Euxine sea; and the Hellespont on the south-west, by which it communicates with the Archipelago. It is one hundred and twenty miles long, and in some places upwards of forty broad.

PROPORTION. When two quantities are compared one with another, in respect of their greatness or smallness, the comparison is called ratio, rate, or proportion. See **ALGEBRA**, **ARITHMETIC**, and **GEOMETRY**.

PROPOSITION, in logic, part of an argument wherein some quality, either negative or positive, is attributed to a subject. See **LOGIC**.

PROPOSITION, in mathematics, is either some truth advanced, and shewn to be such by demonstration; or some operation proposed, and its solution shewn.

PROPREFECT, among the Romans, the prefect's lieutenant, or an officer whom the prefect of the pretorium commissioned to do any part of his duty in his place.

PROPRETOR, a Roman magistrate, who, having discharged the office of pretor at home, was sent into a province to command there with his former pretorial authority.

PROROGATION, the act of prolonging, adjourning, or putting off to another time. The difference between a prorogation and an adjournment of parliament is, that by prorogation the session is ended, as such bills as passed in either house, or both houses, and had not the royal assent, must at the next assembly begin again.

PROSCRIPTION, a publication made in the name of the chief or leader of a party, whereby he promises a reward to any one who shall bring him the head of one of his enemies.

PROSE, the natural language of mankind, loose, and unconfined by poetical measures, rhymes, &c. in which sense it stands opposed to verse.

PROSECUTOR, in law, he that pursues a cause in another's name.

PROSELYTE, a new convert to some religion or religious sect.

PROSPERPINACA, in botany, a genus of the triandria trigynia class. The calix consists of three segments; it has no corolla, and but one seed. There is only one species, a native of Virginia.

PROSODY, that part of grammar which treats of the quantities and accents of syllables. See **GRAMMAR**.

PROSOPOPEIA, a figure in rhetoric, whereby we raise qualities of things inanimate into persons.

PROSTATÆ, in anatomy. See **ANATOMY**, p. 273.

PROSTYLE, in architecture, a range of columns in the front of a temple.

PROTEA, in botany, a genus of the tetrandria monogynia class. The petal consists of four segments surrounding the germen; it has no proper calix; and the receptacle is paleaceous. There are two species, both natives of the Cape of Good Hope.

PROTECTOR, a person who undertakes to defend and defend the weak, helpless, and distressed.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because, in 1520, they protested against a decree of the emperor Charles V. and the diet Spire; declaring that they appealed to a general council. The same name has also been given to those of the sentiments of Calvin, and is now become a common denomination for all those of the reformed churches.

PROTHONOTARY, a term which properly signifies first notary, and which was anciently the title of the principal notaries of the emperors of Constantinople.

PROTOTYPE, is the original or model after which a thing was formed; but chiefly used for the patterns of things to be engraved, cast, &c.

PROTRACTOR, the name of an instrument used for protracting or laying down on paper the angles of a field, or other figure. See **GEOMETRY**.

PROTUBERANCE, is an eminence, whether natural or preternatural, that projects or advances out beyond the rest.

PROVEDITOR, an officer in several parts of Italy, particularly at Venice, who has the direction of matters relating to polity.

PROVENCE, a province or government of France, bounded by Dauphine on the north; by Piedmont on the east; by the Mediterranean on the south; and by the river Rhone, which separates it from Lang edoc, on the west: it is about an hundred miles long, and near as many broad.

PROVERB, according to Camden, is a concise, witty, and wise speech, grounded upon experience, and for the most part containing some useful instructions.

Book of PROVERBS, a canonical book of the Old Testament, containing a part of the proverbs of Solomon the son of David king of Israel. The first twenty-four chapters are acknowledged to be the genuine work of that prince; the next five chapters are a collection of several of his proverbs, made by order of king Hezekiah; and the two last seem to have been added, though belonging to different and unknown authors, Agur the son of Jakeh, and king Lemuel.

In this excellent book are contained rules for the conduct of all conditions of life; for kings, courtiers, masters, servants, fathers, mothers, children, &c.

PROVIDENCE, the conduct and direction of the several parts of the universe, by a superior intelligent Being.

PROVIDENCE-PLANTATION, a colony of New-England, which, with Rhode-Island, constitutes a charter government: its chief town is Newport.

PROVIDENCE is also one of the Bahama islands, planted and fortified by the English: W. long. 78°, N. lat. 25°.

PROVINCE, in Roman antiquity, a country of considerable extent, which, upon being entirely reduced under the Roman dominion, was new-modelled according to the pleasure of the conquerors, and subjected to the command of annual governors sent from Rome; being commonly obliged to pay such taxes and contribution as the senate thought fit to demand.

PROVINCE, in geography, a division of a kingdom or state, comprising

comprising several cities, towns, &c. all under the same government, and usually distinguished by the extent either of the civil or ecclesiastical jurisdiction.

PROVINCIAL, something relating to a province. See the preceding article.

PROVOST, of a city or town, is the chief municipal magistrate in several trading cities, particularly Edinburgh. Paris, &c. being much the same with mayor in other places.

He presides in city-courts, and, together, with the bailiffs, who are his deputies, determines in all differences that arise among citizens.

The provost of Edinburgh, as well as of all the other considerable towns in Scotland, has the title of lord; and the former calls yearly conventions of the royal boroughs to Edinburgh by his messives.

PROW, denotes the head or fore part of a ship, particularly in a galley, being that which is opposite to the poop or stern.

PROXIMITY, denotes the relation of nearness, either in respect of place, blood, or alliance.

PROXY, a person who officiates as a deputy in the room of another.

PRUCH, or **BRUGG**, a town of Austria, in Germany, twenty-two miles south-east of Vienna.

PRUCK, or **BRUCH**, of Stiria, in Germany, sixty miles south-west of Vienna.

PRUNES, are plumbs dried in the sunshine, or in an oven.

PRUNING, in gardening and agriculture, is the lopping off the superfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular.

PRUNUS, in botany, a genus of the icofandria monogynia class. The calix consists of five segments, and the corolla of five petals; and the shell of the drupe is full of prominent sutures. There are 13 species, five of them natives of Britain, *viz.* the infinitia, or black bullace-tree; the spinosa, or sloe-tree; the padus, or birds cherry; the avium, or common wild cherry; and the cerasus, or black cherry.

PRURITIS, denotes an itching sensation.

PRUSSIA, a province of Poland, situated on the coast of the Baltic sea, and divided into regal and ducal Prussia, the first subject to Poland, and the last to the king of Prussia.

PRYTANES, in Grecian antiquity, were the presidents of the senate, whose authority consisted chiefly in assembling the senate; which, for the most part, was done once every day.

The senate consisted of five hundred, fifty senators being elected out of each tribe; after which, lots were cast, to determine in what order the senators of each tribe should preside, which they did by turns, and during their presidentship were called prytanes. However, all the fifty prytanes of the tribes did not govern all at once, but ten at a time, *viz.* for seven days; and after thirty-five days, another tribe came into play, and presided for other five weeks; and so of the rest.

PSALM, a divine song or hymn; but chiefly appropriated to the hundred and fifty Psalms of David, a canonical book of the Old Testament.

Most of the Psalms have a particular title, signifying either the name of the author, the person who was to set it

to music or sing it, the instrument that was to be used, or the subject and occasion of it. Some have imagined, that David was the sole author of the book of Psalms; but the titles of many of them prove the contrary, as Psalm xix. which appears to have been written by Moses. Many of the Psalms are inscribed with the names Korah, Jeduthun, &c. from the persons who were to sing them.

PSALMODY, the art or act of singing psalms. See the preceding article.

PSALTER, the same with the book of Psalms. See **PSALM**.

Among the religious, in the Popish countries, the term psalter is also given to a large chaplet or rosary, consisting of an hundred and fifty beads, according to the number of psalms in the psalter.

PSALTERY, a musical instrument, much in use among the ancient Hebrews, who called it nebel.

We know little or nothing of the precise form of the ancient psaltery.

PSIDIUM, in botany, a genus of the icofandria monogynia class. The calix consists of five segments, and the corolla of five petals; the berry has but one cell, containing many seeds. There are two species, both natives of India.

PSITTACUS, in ornithology, a genus belonging to the order of picæ. The beak is hooked, the superior mandible being furnished with a moveable wax; the nostrils are placed at the base of the beak; the tongue is fleshy, blunt, and entire; and the feet are fitted for climbing. There are 47 species, distinguished by their colour, and the length of their tails. This genus includes the parrot-kind, which are all natives of warm climates.

PSOAS, in anatomy. See **ANATOMY**, p. 203.

PSORALIA, in botany, a genus of the diadelphia decandria class. The calix is interperfed with fleshy points; of the length of the legumen, which contains one seed. There are 14 species, none of them natives of Britain.

PTARMICA, in botany. See **ACHILLEA**.

PTELEA, in botany, a genus of the tetrandia monogynia class. The calix consists of four segments, and the corolla of four petals; the fruit is a roundish membrane, with one seed in the centre. The species are two, none of them natives of Britain.

PTERIS, in botany, a genus of the cryptogamia filicum class. The fructification is situate in lines near the margin. There are 19 species, only one of them, *viz.* the aquilina, or female fern, is a native of Britain.

PTERYGOID, something resembling a wing.

PTERYGOIDÆUS, in anatomy. See **ANATOMY**, p. 221.

PTISAN, is properly barley decorticated, or deprived of its hulls, by beating in a mortar, as was the ancient practice, though the cooling potion, obtained by boiling such barley in water, and afterwards sweetening the liquor with liquorice-root, is what at present goes by the name of ptisan; and to render it laxative, some add a little sena, or other herb of the same intention.

PTOLEMAIC System of Astronomy, is that invented by Claudius Ptolemæus, a celebrated astronomer and mathematician of Pelusium, in Egypt, who lived in the beginning of the 11d century of the Christian æra.

This hypothesis supposes the earth immoveably fixed in the centre, not of the world only, but also of the universe:

verse; and that the sun, the moon, the planets, and stars, all move about it, from east to west, once in twenty-four hours, in the order following, *viz.* the moon next to the earth, then mercury, venus, the sun, mars, jupiter, saturn, the fixed stars, the first and second crystalne heavens, and above all the fiction of their primum mobile.

PTYALISM, in medicine, a salivation, or frequent and copious discharge of saliva.

PUBERTY, among civilians, &c. the age wherein a person is capable of procreation, or begetting children. See **LAW**.

PUBES, among anatomists, &c. denotes the middle part of the hypogastric region of the abdomen, lying between the two inguina or groins. See **ANATOMY**, p. 257.

PUBLICAN, among the Romans, one who farmed the taxes and public revenues.

PUBLICATION, the act of making a thing known to the world; the same with promulgation.

PUDENDA, the parts of generation in both sexes. See **ANATOMY**, p. 270.

PUERILITY, in discourse, is defined by Longinus, to be a thought, which, by being too far-fetched, becomes flat and insipid. Puerility, he adds, is the common fault of those who affect to say nothing but what is brilliant and extraordinary.

FUGIL, in physic, &c. such a quantity of flowers, seeds, or the like, as may be taken up between the thumb and two fore-fingers.

It is esteemed to be the eighth part of the manipule or handful.

PULEX, in zoology, a genus of insects belonging to the order of aptera. It has six feet fitted for leaping, and two eyes; the feelers are like threads; the rostrum is inflected, setaceous, and armed with a sting; and the belly is compressed. There are two species, *viz.* the irritans, with a proboscis shorter than its body, a native of Europe and America; and the penetrans, with a proboscis longer than its body, a native of America.

PULLEY, in mechanics, one of the mechanical powers. See **MECHANICS**.

PULMO, the **LUNGS**, in anatomy. See **ANATOMY**, p. 280.

PULMONARIA, in botany, a genus of the pentandria monogynia class. The corolla is funnel-shaped; and the calix has five sides. There are seven species, two of them natives of Britain, *viz.* the officinalis, or bugloss; slips, the leaves of which are reckoned pectoral and cordiac; and the maritima, or sea-bugloss.

PULMONARY VESSELS, in anatomy. See **ANATOMY**, Part III. and IV. and p. 280.

PULP, in pharmacy, the fleshy and succulent part of fruits, extracted by infusion or boiling, and passed through a sieve.

PULPIT, an elevated place in a church, whence sermons are delivered: the French give the same name to a reading desk.

PULSATILLA, in botany. See **ANEMONE**.

PULSE, in the animal œconomy, denotes the beating or throbbing of the heart and arteries.

With regard to motion, the pulses are reckoned only four, great and little, quick and slow. When quickness and greatness are joined together, it becomes violent; and when it is little and slow, it is called a weak pulse.

They are also said to be frequent and rare, equal and unequal; but these are not the essential affections of motion. Frequency and quickness are often confounded with each other. A pulse is said to be hard or soft, with regard to the artery, according as it is tense, resistant, and hard, or flaccid, soft, and lax. Add to these, a convulsive pulse; which does not proceed from the blood, but from the state of the artery, and is known by a tremulous subultory motion, and the artery seems to be drawn upwards: this, in acute fevers, is the sign of death; and is said to be the pulse in dying persons, which is likewise generally unequal and intermitting. A great pulse shews a more copious afflux of the blood to the heart, and from thence into the arteries; a little pulse, the contrary.

PULSE is also used for the stroke with which any medium is affected by the motion of light, sound, &c. through it.

PULSE, in botany, a term applied to all those grains or seeds which are gathered with the hand, in contradistinction to corn, &c. which are reaped, or mowed: or it is the seed of the leguminous kind of plants, as beans, vetches, &c. but it is by some used for artichokes, asparagus, &c.

PULVERIZATION, the art of pulverizing, or reducing a dry body into a fine powder; which is performed in friable bodies, by pounding or beating them in a mortar, &c.

PULVIS, a **POWDER**. See **POWDER**.

PUMICE, in natural history, a slag or cinder of some fossil, originally bearing another form, and only reduced to this state by the action of the fire, though generally ranked by authors among the native stones. It is a lax and spongy matter, frequently of an obscure striated texture in many parts, and always very cavernous and full of holes; it is hard and harsh to the touch, but much lighter than any other body that comes under the class of stones. It is found in masses of different sizes, and of a perfectly irregular shape, from the bigness of a pigeon's egg, to that of a bushel. We have it from many parts of the world, but particularly from about the burning mountains *Ætna*, *Vesuvius*, and *Hecla*, by whose eruptions it is thrown up in vast abundance; and being by its lightness supported in the air, is carried into seas at some distance by the winds, and thence to distant shores. The great use of the pumice among the ancients, seems to have been as a dentifrice, and at present it is retained in the shops on the same account.

PUMP, in hydraulics. See **HYDROSTATICS**, p. 808. &c. *Air-Pump*. See **PNEUMATICS**, p. 491.

PUN, or **PUNN**, a conceit arising from the use of two words that agree in sound, but differ in the sense. Aristotle describes two or three kinds of puns among the beauties of good writing, and produces instances of them out of some of the greatest authors in the Greek tongue. Cicero has sprinkled several of his works with puns; and in his book, where he lays down the rules of oratory, quotes abundance of sayings, which he calls pieces of wit, that upon examination prove perfect puns.

PUNCH, an instrument of iron or steel, used in several arts, for the piercing or stamping holes in plates of metal, &c. being so contrived as not only to perforate, but to cut out and take away the piece.

PUNCHEDON, a little block or piece of steel, on one end whereof is some figure, letter, or mark, engraven either

In creek or rivulet; impositions whereof are taken on metal, or some other matter, by striking it with a hammer on the end not engraved.

PUNCHON is also a measure for liquids, containing an hog-head and one third, or eighty-four gallons.

PUNCTUATION, in grammar, the art of pointing, or of dividing a discourse into periods, by points expressing the pauses to be made in the reading thereof.

PUNCTUM SALIENS, in anatomy, the first rudiments of the heart in the formation of the focus, where a throbbing motion is perceived.

PUNCTURE, in surgery, any wound made by a sharp-pointed instrument.

PUNICA, the **POMEGRANATE-TREE**, in botany, a genus of the icolandria monogynia class. The calix consists of five segments, and the corolla of five petals; the apple has many cells, containing many seeds. There are two species, both natives of warm climates.

PUNISHMENT, in law, the penalty which a person incurs on the breach or transgression of any law.

PUPIL, in the civil law, a boy or girl not yet arrived at the age of puberty, *i. e.* the boy under fourteen years, the girl under twelve.

PUPIL is also used in universities, &c. for a youth under the education or discipline of any person.

PUPIL, in anatomy. See **ANATOMY**, p. 289.

PURCHASE, in law, the buying or acquiring of lands, &c. with money, by deed or agreement, and not by descent or right of inheritance.

PURE, something free from any admixture of foreign or heterogeneous matters: thus we say pure fire, &c.

PURFLEW, a term in heraldry, expressing ermins, peans, or any of the furs, when they compose a bordure round a coat of arms: thus they say, he beareth gules a bordure, purflew, vary; meaning that the bordure is vary.

PURGATION, the art of purging, scouring, or purifying a thing, by separating, or carrying off any impurities found therein: thus,

PURGATIVE, a medicament which evacuates the impurities of the body by stool, called also cathartics.

PURGATORY, a place in which the just who depart out of this life, are supposed to expiate certain offences which do not merit eternal damnation.

Broughton has endeavoured to prove, that this notion has been held by Pagans, Jews, and Mahometans, as well as by Christians.

The doctrine of purgatory is a very lucrative article to the clergy of the Romish church, who are very liberally paid for masses and prayers for the souls of the deceased. We are told by some of their doctors, that purgatory is a subterraneous place situated over the hell of the damned, where such souls as have not yet made satisfaction to divine justice for their sins, are purged by fire, after a wonderful and incomprehensible manner: and here they are purified from those dregs which hinder them from entering into their eternal country, as the catechism of the council of Trent expresses it.

PURIFICATION, in matters of religion, a ceremony which consists in cleansing any thing from a supposed pollution or defilement.

The Pagans, before they sacrificed, usually bathed or washed themselves in water; and they were particularly careful to wash their hands, because with these they were

to touch the victims consecrated to the gods. It was also customary to wash the vessel with which they made their libations. The Mahometans use purifications as previous to the duty of prayer: these also are of two kinds; either bathing; or only washing the face, hands and feet. The first is requested only in extraordinary cases, as after having lain with a woman, touched a dead &c. But lest too necessary a preparation for their devotion should be omitted, either where water cannot be had or when it may be of prejudice to a person's health, they are allowed in such cases to make use of fine sand or dust instead of it; and then they perform this duty by clapping their open hands on the sand, and passing them over the parts, in the same manner as if they were dipped in water.

There were also many legal purifications among the Hebrews. When a woman was brought to bed of a male-child, she was esteemed impure for forty days; and when of a female, for sixty; at the end of which time she carried a lamb to the door of the temple, to be offered for a burnt-offering, and a young pigeon or turtle for a sin-offering, and by this ceremony she was cleansed or purified.

PURIM, or the *feast of lots*, a solemn festival of the Jews, instituted in memory of the deliverance they received from Haman's wicked attempt to destroy them, by means of Mordecai and Esther.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of their professing to follow the pure word of God, in opposition to all traditions and human constitutions.

PURLINS, in building, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

PURLUE, or **PURLIEU**, signifies all that ground near any forest, which being made forest by king Henry II. Richard I. and king John, was afterwards by perambulations and grants of Henry III. severed again from the same, and made purlieu; that is to say, pure and free from the laws of the forest.

PURPLE, a colour composed of a mixture of red and blue.

A beautiful transparent purple for painting may be made by boiling four ounces of rasped brazil-wood in a pint of stale beer, and half an ounce of logwood, till the liquor is heightened to the colour you desire, which may be known by dipping a piece of paper in it. If you find it too red, add a quarter of an ounce more of logwood, which will render it still deeper; and by this method you may bring it to any degree of purple, by putting in either more or less logwood to the former composition, and fixing it with alum.

PURPURA, in natural history. See **MUREX**.

PURPURE, or **PURPLE**, in heraldry, according to some, is one of the five colours of armories compounded of gules and azure, bordering on violet, and, according to others, of a great deal of red and a little black. But it was excluded by the ancient heralds as only an imperfect colour. In the coats of noblemen it is called amethyst; and in those of princes, mercury. It is represented in engraving, by diagonal lines drawn from the sinister chief to the dexter base points. See **PLATE CXLVII. fig. 3.**

PURSER, an officer aboard a man of war, who receives her victuals from the victualler, sees that it be well stowed, and

and keeps an account of what he every day delivered to the steward. He also keeps a list of the ship's company, and sets down exactly the day of each man's admission, in order to regulate the quantity of provisions to be delivered out; and that the paymaster or treasurer of the navy may issue out the disbursements, and pay off the men, according to his book.

PURSLAIN, in botany. See **PORTULACA**.

PURVIEW, a term used by some lawyers for the body of an act of parliament, or that part which begins with, Be it enacted, &c. as contradictinghished from the preamble.

PURULENT, in medicine, something mixed with, or partaking of, pus or matter.

PUS, in medicine, a white or yellowish putrid matter, designed by nature for the healing and cementing of wounds or sores.

PUSTULE, a pimple, or small eruption on the skin full of pus; such are the pustules of the small-pox and trench-pox. See **MEDICINE**.

PUTORIUS, in zoology. See **MUSTELA**.

PUTREFACTION. See **CHEMISTRY**, p. 98.

PUTTY, is a kind of paste, compounded of whiting and linseed oil, beaten together to the consistence of thick dough.

It is used by glaziers for the fastening in the squares of glass in sash-windows, and by painters for stopping up the crevices and clefts in timber and wainscots, &c.

PYCNOSTYLE, in the ancient architecture, is a building where the columns stand very close to each other; only one diameter and a half of the column being allowed for the intercolumniations.

PYGARGUS, in ornithology. See **FALCO**.

PYGMY, a person not exceeding a cubit in height.

This appellation is given by the ancients to a fabulous nation said to have inhabited Thrace; who brought forth young at five years of age, and were old at eight; these were famous for the bloody war they waged with the cranes.

PYLORUS, in anatomy. See **ANATOMY**, p. 238.

PYRAMID, in geometry, a solid standing on a triangular, square, or polygonal basis, and terminating in a point at the top; or, according to Euclid, it is a solid figure, consisting of several triangles, whose bases are all in the same plane, and have one common vertex.

PYRAMID, in architecture, a solid massive building, which from a square, triangular, or other base, rises diminishing to a vertex or point.

Pyramids are sometimes used to preserve the memory of singular events; and sometimes to transmit to posterity the glory and magnificence of princes. But as they are esteemed a symbol of immortality, they are most commonly used as funeral monuments. Such is that of Cestus at Rome; and these other celebrated ones of Egypt, as famous for the enormity of their size, as their antiquity. These are situated on the west side of the Nile, almost opposite to Grand Cairo: the base of the largest covers more than ten acres of ground; and is, according to some, near seven hundred feet high; though others make it but six hundred, and some but little more than five hundred. The pyramid is said to have been, among the Egyptians, a symbol of human life; the beginning of which is represented by the base, and the end by the

apex; on which account it was that they used to erect them over sepulchres.

PYRAMIDALIA CORPORA, in anatomy. See **ANATOMY**, p. 237.

PYRAMIDALIS, in anatomy. See **ANATOMY**, p. 193.

PYRENEAN MOUNTAINS divide France from Spain, and are not inferior to the Alps in height: they extend from the Mediterranean to the ocean, upwards of two hundred miles in length, the greatest breadth being about one hundred and twenty.

PYRIFORMIS, in anatomy. See **ANATOMY**, p. 205.

PYRITES. See **CHEMISTRY**, p. 117.

PYRMONT, the capital of a county of that name in the circle of Westphalia in Germany, situated on the confines of the duchy of Brunswick, in E. long. 9°. N. lat. 52°, from whence we receive the best mineral waters in Germany.

PYROLA, in botany, a genus of the decandria monogynia class. The calix consists of five segments, and the corolla of five petals; and the capsule has five cells. There are six species, three of them natives of Britain, viz. the rotundifolia, or common winter-green; the minor, or lesser winter-green; and the secunda, or dented leaved winter-green.

PYROMANCY, a kind of divination by means of fire.

The ancients imagined they could foretell future events, by inspecting fire and flame; and to this end, they considered its direction, which way it turned; sometimes they added other matters to the fire, such as a vessel full of urine, having its neck bound about with wool, watching narrowly on which side it burst, and thence taking their augury: sometimes they threw pitch on it; and, if it took fire immediately, they esteemed it a good augury.

PYROTECHNY, the art of fire, or a science which teaches the management and application of fire in several operations. See **CHEMISTRY**.

PYROTICS, in medicine, caustics, or remedies, either actually or potentially hot; and which accordingly will burn the flesh, and raise an eschar. See **CAUSTICS**.

PYRRHICHA, in antiquity, a kind of exercise on horseback, or a feigned combat, for the exercise of the cavalry.

PYRRHICIUS, in the Greek and Latin poetry, a foot consisting of two syllables, both short; as, *Deur*.

PYRRHONIANS, a sect of ancient philosophers, so called from Pyrrho, a native of Elis, in Peloponnesus. The opinions of these philosophers, who were also called sceptics, terminated in the incomprehensibility of all things, in which they found reason both for affirming and denying; accordingly they seemed, during their whole lives, to be in search of truth, without ever acknowledging that they had found it: hence the art of disputing upon all things, without ever going farther than suspending our judgment, is called pyrrhonism.

PYRUS, in botany, a genus of the icofandria pentagynia class. The calix consists of 5 segments, and the corolla of five petals; the apple has five cells, containing many seeds. There are four species, two of them natives of Britain, viz. the communis, or wild pear-tree; and the malus, or crab-apple.

PYTHAGOREANS, a sect of ancient philosophers, so called from their being the followers of Pythagoras of Samos, who lived in the reign of Tarquin the last king of the Romans, in the year of Rome 220; or, according

to Livy, in the reign of Servius Tullius, in the year of the world 3472.

His maxims of morality were admirable; for he was for having the study of philosophy solely tend to elevate man to a resemblance of the Deity. He believed that God is a soul diffused through all nature, and that from him human souls are derived; that they are immortal; and that men need only take pains to purge themselves of their vices, in order to be united to the Deity. He made unity the principle of all things; and believed, that between God and man there are various orders of spiritual beings, who are the ministers of the Supreme Being. He condemned all images of the Deity, and would have him worshipped with as few ceremonies as possible. His disciples brought all their goods into a common stock, contemned the pleasures of sense, abstained from swearing, eat nothing that had life, and believed in the doctrine of a metempsychosis. See *METEMPSYCHOSIS*.

Pythagoras made his scholars undergo a severe noviciate of silence for at least two years; and it is said, that where he discerned too great an itch for talking, he extended it to five. His disciples were therefore divided into two classes: of which the first were simple hearers;

and the last such as were allowed to propose their difficulties, and learn the reasons of all that was taught there. The Pythagoreans, it is said, on their rising from bed, roused the mind with the sound of the lyre, in order to make them more fit for the actions of the day; and at night resumed the lyre, in order to prepare themselves for sleep, by calming all their tumultuous thoughts. The figurative manner in which he gave his instructions, was borrowed from the Hebrews, Egyptians, and other orientals. Some think he derived his philosophy from the books of Moses, and that he conversed with Ezekiel and Daniel at Babylon; but this is mere conjecture.

Some authors say, that he left nothing in writing; but Lactantius and others attribute several treatises to him. His golden verses, attributed by some to one of his disciples, are allowed to be an exact copy of the sentiments of that divine philosopher, from whose school proceeded the greatest philosophers and legislators.

PYTHIA, in antiquity, the priestess of Apollo at Delphi, by whom he delivered oracles; she was thus called from the god himself, who was denominated Apollo Pythios, from his slaying the serpent Python.

Q.

Q U A

QUACK, among physicians, the same with empiric. See *EMPIRIC*.

QUADRAGESIMA, a denomination given to lent, from its consisting of forty days. See *LENT*.

QUADRANGLE, in geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles.

QUADRANS, the quarter or fourth part of any thing, particularly the *as*, or pound.

QUADRANT, in geometry, the arch of a circle, containing 90°, or the fourth part of the entire periphery.

QUADRANT also denotes a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars. See *ASTRONOMY*, p. 451.

QUADRAT, a mathematical instrument, called also a geometrical square, and line of shadows: it is frequently an additional member on the face of the common quadrant, as also on those of Gunter's and Sutton's quadrant.

QUADRAT, in astrology, the same with quartile. See *QUARTILE*.

QUADRAT, in printing, a piece of metal cast like the letters, to fill up the void spaces between words, &c. There are quadrats of different sizes, as m-quadrats, n-quadrats, &c. which are, respectively, of the dimensions of these letters.

QUADRATIC EQUATION, in algebra. See *ALGEBRA*, p. 60.

QUADRATRIX, in geometry, a mechanical line, by means whereof we can find right lines equal to the circumference of circles, or other curves, and their several parts.

QUADRATRIX of Dinostratus, so called from its inventor

Dinostratus, is a curve, whereby the quadrature of the circle is effected mechanically.

QUADRATURE, in geometry, denotes the squaring, or reducing a figure to a square. Thus, the finding of a square, which shall contain just as much surface or area as a circle, an ellipsis, a triangle, &c. is the quadrature of a circle, ellipsis, &c. See *GEOMETRY*.

QUADRATURE, in astronomy, that aspect of the moon, when she is 90° distant from the sun. See *ASTRONOMY*.

QUADRATUS, in anatomy, a name given to several muscles on account of their square figure. See *ANATOMY*, Part II.

QUADREL, in building, a kind of artificial stone, so called from its being perfectly square.

The quadrels are made of chalky earth, &c. and dried in the shade for two years. These were formerly in great request among the Italian architects.

QUADRIENNIUM UTILE, in Scots law. See *LAW*, Tit. vii. 17.

QUADRIGA, in antiquity, a car or chariot drawn by four horses.

On the reverses of medals, we frequently see the emperor or victory in a quadriga, holding the reins of the horses; whence these coins are, among the curious, called nummi quadrigati, and victoriat.

QUADRILATERAL, in geometry, a figure whose perimeter consists of four right lines, making four angles; whence it is also called a quadrangular figure.

QUADRILLE, a little troop or company of cavaliers, pompously dressed, and mounted for the performance of carousals,

roufais, juffs, tournaments, runnings at the ring, and other gallant divertifements.

QUADRILLE, is alfo a game at cards, to be learned only by practice.

QUADRUPEDS, in zoology. See **NATURAL HISTORY**.

QUASI CONTRACT, in Scots law. See **LAW**, Tit. xxii. 14.

QUESTUS, in law, fignifies whatever a perfon has by purchafe; as hereditas denotes that which one has by defcent, or hereditary right.

QUAIL. See **TETRAO**.

QUAKERS, a religious fociety that began to be diftinguifhed by this name in England, where it firft took its rife, about the middle of the laft century.

In treating of this people, we fhall deviate from the generality of thofe who have mentioned them in their writings, by exhibiting the account which they give of themfelves, without making ourfelves anfwerable for their principles or their practices.

William Sewel, a Dutchman, published, in the year 1717, the hiftory of this people. He was one of their perfuafion, a man of learning, and known to the public by his dictionary of the Dutch and Englifh languages. He had accels to all their records, correponded with the moft eminent, lived at the time when the facts he recorded were recent, and we have not heard that any part of his hiftory has been controverted; and as we are informed that it has been publifhed by the approbation of the quakers, we may therefore confider it as an authentic hiftory of their rife, progreff, and principal opinions.

George Fox, (for whofe birth and parentage, fee page 6th of Sewel's Hiftory, &c.) was the firft of this people. He was of a grave, fedate turn from his infancy; always averfe to the follies of youth, and defirous of nothing fo much as to be preferved in innocence and fimplicity. He was early remarked as an example in thefe refpects, and of inflexible integrity. When a youth, he was defirous above all things to pleafe God, and cautiously avoided every thing that either fcripture or the dictates of his own confcience taught him to believe were offensive. As he grew up, this difpofition increafed: it coft him much anxiety, much diftrefs; but at length he was fatifhed in refpect to many doubts he had admitted, and gained much experience by the things he had fuffered. This enabled him to inftruct others; and about the year 1647, we find him travelling through feveral countries in England, seeking out fuch as had any religious tendernes, and exciting the inquiries of many concerning him. Many embraced his opinions; and indeed he feems to have roused the public mind as much as any individual ever did in thofe countries, for the time and under fuch circumftances. A man of low birth, without literature, merely by the fandity of his life, the fimplicity of his doctines, to have collected from all profelfions, and moft ranks, men of character, fortune, and understanding, and embodied them as a religious fociety; to have inftituted one of the beft concerted plans of civil difcipline; is a circumftance moft true, and not unworthy the difquifitions of the ableft philofophers.

The name of *Quaker* was fixed to this people early, by way of reproach. In their afsemblies it fometimes happened, that fome were fo far ftruck with the remembrance of their paff follies and forgetfulnefs of their condition, others fo deeply affected with a fenfe of God's

mercies to them, that they actually trembled and quaked. The nickname fo fued the vulgar taite, that it immediately became general. *Friends*, or *the friends of truth* was the name they were commonly known by to one another; but the epithet abovementioned was ftamped upon them by their adverfaries, and perhaps indelibly.

The following abftract from the propofitions of our countryman, the eminent Barclay, will perhaps exhibit as clear a fummary of their opinions as can well be comprifed within the limits allowed to this article.

1. The height of all happinefs is placed in the true knowledge of God. 2. The true knowledge of God is alone to be obtained by the revelation of the Spirit of God. 3. The revelation of the Spirit of God to the faints has produced the fcriptures of truth. 4. From whence it appears, that mankind in general is fallen and degenerated. 5. That God out of his infinite love hath offered univerfal redemption by Chrift, who tafted death for every man. 6. That there is an evangelical and faving light and grace in all. 7. That as many as refift not this light, but receive the fame, in them are produced holinefs, righteoufnefs, purity, and the fruits which are acceptable to God: 8. Even fo as to arrive at a ftate of freedom from actual finning and tranfgreffing the law of God; 9. Yet with a poffibility of finning. 10. That as all true knowledge in things fpiritual is received by the Spirit of God, fo by it every true minifter of the gofpel is ordained and prepared for the miniftry; and as they have freely received, fo are they freely to give. 11. That the true worfhip of God is in fpirit and in truth; not limited to place or time, or fubject to the intervention of any perfon; but is to be performed under the moving of the Holy Spirit in our hearts, yet without derogating from the neceffity and utility of public united worfhip, (in which their fufferings and conftancy have been moft remarkable) 12. That baptifm is a pure and fpiritual thing, the baptifm of the fpirit and fire. 13. That the communion of the body and blood of Chrift is inward and fpiritual. 14. That it is not lawful for any human authority to force the confciences of others on account of difference in worfhip or opinion, except fuch opinions tend to the prejudice of his neighbour in his life or eftate, or are inconffiftent with human fociety. 15. That as the end of religion is to redeem man from the fpirit of this world, and to lead into inward communion with God; therefore all vain cuftoms and habits are to be rejected, which tend to divert the mind from a fenfe of the fear of God; and that evangelical fpirit wherewith Chriftians ought to be leavened.

Such are the sentiments of this people as propofed to the public by their apologet, who has largely commented on thefe topics in a work that has paffed through no lefs than eight editions in Englifh, and has been printed in moft of the modern languages.

Their particularities of addrefs, language, and behaviour; their declining the ufe of arms, even in their own defence; their refufing to pay tithes, or contribute to the fupport of minifters in any fhape; likewife their refufing to swear or take an oath on any occafion whatever; have fubjected them to much obloquy, and many grievous fufferings. On what principles, and by what arguments, they vindicate themfelves from the objections raifed againft them by their adverfaries, may be feen in this elaborate

borate performance. Government has, however, in many instances, extended to this people great indulgencies; convinced, no doubt, by their patient suffering, that their professions of conscientious scruples were sincere, and that nothing dangerous to society could be apprehended from a people who disclaimed the use of arms both offensive and defensive. The æconomy of this society likewise deserves our notice. It appears by their history, that soon after the preaching of George Fox had drawn together in many parts of England considerable bodies of people professing the same opinions, he found it expedient for their better government to establish regular meetings for discipline. The following is, as nearly as we can collect, the plan that is established amongst them.

Where there are any Quakers, they meet together every month, to consider of the necessities of their poor, and to provide for their relief; to hear and determine complaints arising among themselves; to inquire into the conversation of their respective members in regard to morality and conformity to their religious sentiments; to allow the passing of marriages; and to enjoin a strict regard to the peace and good order of the society, the proper education of their young people, and a general attention to the principles and practices of their professions. In every country where there are monthly meetings, a meeting of the like kind is held, and for similar purposes, every quarter. This meeting consists of deputies sent from the several monthly meetings, who are charged with answers in writing to queries proposed to them respecting the good order of the society. At these meetings appeals are received, in case of any disputes; and differences settled, if possible. Advices are given as occasions offer, and assistance afforded to any of the monthly meetings, in case of a larger proportion of poor, or any similar expences. As there are Quakers in most parts of England, there are few counties which have not these quarterly meetings. And from these are deputed 4, 6 or 8 of their members once a year to their annual assembly at London.

The annual meeting is commonly held in Whitfun-week, not from any superstitious reference, as they say, to the effusion of the Holy Ghost at the time of petecost, but merely as it is a season most generally convenient to the body. At this anniversary meeting, consisting of deputies from every quarterly meeting, and a number of the most judicious of their persuasion in London, selected for the purpose of acting on all emergencies for the good of the society, accounts are received of the state of the society in every part of the world where it exists. The deputies bring with them accounts signed by order of the respective quarterly meetings, informing the yearly meeting, if any disunion appears; if there is any neglect in regard to the religious education of their youth; if the poor are well provided for; if they keep to their testimony against paying tithes, against bearing arms; if they pay the king his duties, customs, and excise, and forbear to deal in goods suspected to be run. Appeals are here received, and finally determined; propositions received, and considered; and rules formed on particular emergencies: And, lastly, such advices are sent to the subordinate meetings as the particular or general state of the society requires.

Perhaps this is the only society in the world that have al-

lowed any share in the management of their affairs to the female sex; which they do upon the principle that male and female are one in Christ. Accordingly we find them in every department of their institution. They have women-preachers, for whom the celebrated Locke made an excellent apology. They have also their meetings of discipline; in which the like care is taken in regard to the female youth, and the good order of their sex, as is done by the men in respect to their own. And when we reflect what a number of individuals of both sexes are kept in good order by the police of this society, how few of them are brought into courts of justice as delinquents, how peaceable their behaviour, and how exemplary their conduct, we cannot but think their principles deserve a more accurate examination than has hitherto been attempted, owing perhaps to the vulgar prejudices circulated against them. We shall close this article with observing, that, according to the best of our information, neither their ministers, nor those who have the principal care of the society, enjoy any pecuniary emolument or advantages. A few clerks only receive salaries for keeping their records; so that perhaps there is not a religious society now existing, where principle has greater influence in promoting the ends of their institution.

It is remarkable, that all the settlements of the Europeans in America, except the Quaker settlement of Pennsylvania, were made by force of arms, with very little regard to any prior title in the natives. The kings of Spain, Portugal, France, and Britain, together with the States of Holland, then the only maritime powers, gave grants of such parts of America as their people could lay hold on, studying only to avoid interference with their European neighbours. But Mr Penn, being a Quaker, did not think his powers from king Charles II. a sufficient title to the country since called Pennsylvania: He therefore assembled the sachems or princes then in that country, and purchased from them the extent of land that he wanted. The government of this province is mostly in the hands of the Quakers, who never have any quarrels with the natives. When they desire to extend their settlements, they purchase new lands of the sachems, never taking any thing from them by force. How unlike is this conduct to that of the Spaniards, who murdered millions of the natives of Mexico, Terra Firma, Peru, Chili, &c. The barbarities used to these poor Indians in conquering their country, and forcing them to discover their gold, are a reproach to human nature.

QUALITY, is defined by Mr Locke, to be the power in a subject of producing any idea in the mind. See METAPHYSICS.

Chemical QUALITIES, those qualities principally introduced by means of chemical experiments, as fumigation, amalgamation, cupellation, volatilization, precipitation, &c. See CHEMISTRY.

QUALITY is also used for a kind of title given to certain persons, in regard of their territories, signories, or other pretensions.

QUAMSI, a province of China, bounded by the province of Yunan on the west, by Queycheu on the north, by Quantum on the east, and by Tongquin on the south.

QUAMTUM, or **CANTON**, a province of China, bounded by Huguan and Kiamfi on the north, by Foken on the east, by the ocean on the south, and by Quamfi on the west.

QUANTITY, any thing capable of estimation, or mensuration; or which, being compared with another thing of the same kind, may be laid to be greater or less than it, equal or unequal to it. See **ARITHMETIC**, **ALGEBRA**, **GEOMETRY**.

QUANTITY, in grammar, an affection of a syllable, whereby its measure, or the time wherein it is pronounced, is ascertained; or that which determines the syllable to be long or short.

QUARANTINE, is used for a term of forty days, which vessels, coming from places suspected of contagion, are obliged to wait in certain places appointed to air themselves, before they come into port. See **LAZAR-HOUSE**.

QUARRY, a place under ground, out of which are got marble, free-stone, slate, lime-stone, or other matters proper for buildings.

QUARRY or **QUARREL**, among glaziers, a pane of glass, cut in a diamond form.

QUART, a measure containing the fourth part of some other measure.

QUARTAN, in medicine, a species of intermitting fever. See **MEDICINE**.

QUARTATION, a method of purifying gold, by melting three parts of silver with one of gold, and then throwing the mixture into aqua-fortis. See **CHEMISTRY**, p. 129.

QUARTER, the fourth part of any thing.

Quarter, in weights, is generally used for the fourth part of an hundred weight avoirdupois, or 28 lb.

Used as the name of a dry measure, quarter is the fourth part of a ton in weight, or eight bushels.

QUARTER, in astronomy, the fourth part of the moon's period.

QUARTER, in heraldry, is applied to the parts or members of the chief division of a coat that is quartered, or divided into four quarters. See **QUARTERING**.

Franc-Quarter, in heraldry, is a quarter single or alone; which is to possess one fourth part of the field.

This makes one of the honourable ordinaries of a coat.

QUARTER MASTERS, or **QUARTERS**, in a man of war, are officers whose business it is to rummage, stow, and trim the ship in the hold; to overlook the steward in his delivery of victuals to the cook, and in pumping or drawing out beer, or the like. They are also to keep their watch duly, in conning the ship, or any other duty.

QUARTER MASTER, an officer in the army, whose business is to look after the quarters of the soldiers; of which there are several kinds, viz. The quarter-master general, whose business is to provide good quarters for the whole army; quarter-master of horse, he who is to provide quarters for a troop of horse; quarter-master of foot, he who is to provide quarters for a regiment of foot.

QUARTERING, in the sea language, is disposing the ship's company at an engagement, in such a manner as that each may readily know where his station is, and what he is to do.

QUARTERING, in heraldry, is dividing a coat into four or more quarters, or quarterings, by parting, coupling, &c. that is, by perpendicular and horizontal lines, &c.

QUATUOR-VIRI, in antiquity, formerly written **III. VIRI**, a Roman magistrate who had three colleges joined with him in the same administration, and had the care of conducting and settling the colonies sent into the provinces.

There were also quatuor-viri appointed to inspect and take care of repairs, &c.

QUAVER, in music, a measure of time equal to half a crotchet, or an eighth of a semibreve. See **MUSIC**.

QUEBEC, the capital of Canada, in North America, situated on the west side of the river of St Lawrence, 300 miles north-west of Boston in New England: W. long. 74°. N. lat. 47° 35'.

QUEEN, a woman who holds a crown singly.

The title of queen is also given by way of courtesy to her that is married to a king, who is called by way of distinction queen-consort; the former being termed queen-regent. The widow of a king is also called queen, but with the addition of dowager.

QUEEN'S-COUNTY, a county of Ireland, bounded by King's-county, on the north; by Kildare, on the east; by Kilkenny, on the south; and by the province of Munster, on the west.

QUEEN'S FERRY, a town of Scotland, on the south side of the river Forth, ten miles west of Edinburgh.

QUEENBOROUGH, a borough to the north of the city of Shepp, in Kent, twelve miles north-west of Canterbury. It sends two members to parliament.

QUERCUS, in botany, a genus of the monœcia polyandria class. The calix of the male has five segments; it has no corolla; and the stamina are from five to ten. The calix of the female is one entire, rough leaf; it has no corolla; the styli are from two to five; and the seed is ovate. There are 14 species. only one of them, viz. the robur, or common oak, a native of Britain.

QUERCY, the south-east division of the province of Guienne, in France, have Limosin on the north, and Languedoc on the south.

QUERIA, in botany, a genus of the triandria trigynia class. The calix consists of five leaves; it has no corolla; and the capsule has one cell and one seed. There are two species, none of them natives of Britain.

QUESTION, in logic, a proposition proposed by way of interrogation. See **LOGIC**.

QUESTOR, in Roman antiquity, an officer who had the management of the public treasure.

The questorship was the first office any person could bear in the commonwealth, and gave a right to sit in the senate.

At first there were only two; but afterwards two others were created, to take care of the payment of the armies abroad, of the selling plunder, booty, &c. for which purpose they generally accompanied the consuls in their expeditions; on which account they were called peregrini, as the first and principal two were called urbani.

The number of questors was afterwards greatly increased. They had the keeping of the decrees of the senate; and hence came the two offices of questor principis, or augustinus, sometimes called candidatus principis, whose office resembled in most respects that of our secretaries of state; and the questor palatii, answering in a great measure to our lord chancellor.

QUEUE, in heraldry, signifies the tail of a beast: thus if a lion be borne with a forked tail, he is blazoned double queued.

QUICK, or **QUICKSET HEDGE**, among gardeners, denotes all live hedges, of whatever sort of plants they are composed, to distinguish them from dead hedges: but in a

more strict sense of the word, it is restrained to those planted with the hawthorn, under which name these young plants, or sets, are sold by the nursery-gardeners who raise them for sale.

QUICKSILVER. See **CHEMISTRY**, p. 85.

QUIETISTS, a religious sect, which made a great noise towards the close of the last century.

They were so called from a kind of absolute rest and inaction, which they supposed the soul to be in when arrived at that state of perfection which they called the unitive life; in which state, they imagined the soul wholly employed in contemplating its God, to whose influence it was entirely submissive, so that he could turn and drive it where and how he would. In this state, the soul no longer needs prayers, hymns, &c. being laid, as it were, in the bosom, and between the arms of its God, in whom it is in a manner swallowed up.

The Mahometans seem to be no strangers to quietism. They expound a passage in the seventieth chapter of the Koran, viz. *O thou soul, which art at rest, return unto thy Lord*, &c. of a soul, which having, by pursuing the concatenation of natural causes, raised itself to the knowledge of that Being which produced them, and exists of necessity, rests fully contented, and acquiesces in the knowledge, &c. of him, and in the contemplation of his perfections.

QUILLS, the large feathers taken out of the end of the wing of a goose, crow, &c.

Quills are denominated from the order in which they are fixed in the wing, the second and third quills being the best for writing, as they have the largest and roundest barrels.

In order to harden a quill that is soft, thrust the barrel into hot ashes, stirring it till it is soft; then taking it out, press it almost flat upon your knee with the back of a pen-knife, and afterwards reduce it to a roundness with your fingers. If you have a number to harden, set water and alum over the fire; and while it is boiling put in a handful of quills, the barrels only, for a minute, and then lay them by.

QUINCE, in botany. See **PERUS**.

QUINCUNX, in Roman antiquity, denotes any thing that consists of five twelfth-parts of another, but particularly of the as.

QUINDECAGON, in geometry, a plain figure with fifteen sides and fifteen angles.

QUINDECIMVIRI, in Roman antiquity, a college of 15 magistrates, whose business it was to preside over the sacrifices.

They were also the interpreters of the Sibyl's books; which, however, they never consulted but by an express order of the senate.

QUINQUAGENARIUS, in Roman antiquity, an officer who had the command of fifty men.

QUINQUAGESIMA SUNDAY, Shrove Sunday, so cal-

led as being about the fiftieth day before Easter.

QUINQUATRIA, in Roman antiquity, festivals celebrated in honour of Minerva, with much the same ceremonies as the panathenæa were at Athens.

QUINQUEFOLIUM, in botany. See **POTENTILLA**.

QUINQUENNALIS, in Roman antiquity, a magistrature in the colonies and municipal cities of that empire, who had much the same office as the ædile at Rome.

QUINQUEREMIS, in antiquity, a galley with five rows of oars.

QUINQUEVIRI, in Roman antiquity, an order of five priests, peculiarly appointed for the sacrifices to the dead, or celebrating the rites of Erebus.

QUINQUINA. See **CINCHONA**.

QUINTESSENCE, in chemistry, a preparation consisting of the essential oil of some vegetable substance mixed and incorporated with spirit of wine.

QUINTESSENCE, in alchemy, is a mysterious term, signifying the sixth, or last and highest essence of power or a natural body.

QUINTILE, in astronomy, an aspect of the planets, when they are 72 degrees distant from one another, or a fifth part of the zodiac.

QUINTILIANS, a sect of ancient heretics, thus called from their prophetess Quintilia. In this sect the women were admitted to perform the sacerdotal and episcopal functions. They attributed extraordinary gifts to Eve for having first eaten of the tree of knowledge; told great things of Miriam the sister of Moses, as having been a prophetess, &c. They added that Philip the deacon had four daughters who were all prophetesses, and were of their sect. In these assemblies it was usual to see the virgins entering in white robes, personating prophetesses.

QUINZY, **QUINSEY**, or **ANGELINA**. See **MEDICINE**, p. 84.

QUIRE of paper, the quantity of 24 or 25 sheets.

QUIRINALIA, in antiquity, a feast celebrated among the Romans in honour of Romulus, who was called Quirinus. These feasts were held on the 13th of the kalends of March.

QUIRITES, in antiquity, a name given to the people of Rome, chiefly the common citizens, as distinguished from the soldiery.

QUOIN, or **COIN**, on board a ship, a wedge fastened on the deck close to the breech of the carriage of a gun, to keep it firm up to the ship-side.

Cantic quoins are short three-legged quoins put between casks to keep them steady.

QUOINS, in architecture, denote the corners of brick or stone walls. The word is particularly used for the stones in the corners of brick-buildings. When these stand out beyond the brick-work, their edges being chamfered off, they are called rustic quoins.

QUOTIDIAN, in medicine. See **MEDICINE**, p. 62.

QUOTIENT, in arithmetic. See **ARITHMETIC**, p. 376.

R.

R A B

R AAB, a city of Lower Hungary, situated at the confluence of the rivers Danube and Raab, and subject

R A B

to the house of Austria: E long. 18°, N. lat. 48°. **RABBI**, or **RABBINS**, a title which the pharisees and doc-

rors of the law among the Jews assumed, and literally signifies matters, or excellents.

There were several gradations before they arrived at the dignity of a rabbin, which was not conferred till they had acquired the profoundest knowledge of the law and the traditions. It does not however appear, that there was any fixed age, or previous examination necessary; but when a man had distinguished himself by his skill in the written and oral law, and passed through the subordinate degrees, he was saluted a rabbin by the public voice.

Among the modern Jews, for near seven hundred years past, the learned men retain no other title than that of rabbi, or rabbins; they have great respect paid them, have the first places or seats in their synagogues, determine all matters of controversy, and frequently pronounce upon civil affairs; they have even a power to excommunicate the disobedient.

RABBIT, in zoology. See **LEPUS**.

RACE, in general, signifies running with others in order to obtain a prize, either on foot, or by riding on horseback, in chariots, &c.

RACE, in genealogy, a lineage or extraction continued from father to son.

RACHITIS, the **RICKETS**. See **MEDICINE**, p. 169.

RACK, an engine of torture, furnished with pulleys and cords, &c. for extorting confession from criminals.

RACK, a spirituous liquor made by the Tartars of Tongusia. This kind of rack is made of mare's milk, which is left to be sour, and afterwards distilled twice or thrice between two earthen pots closely stopped, from whence the liquor runs through a small wooden pipe. This liquor is more intoxicating than brandy distilled from wine.

Rack is also a spirituous liquor which the English get from Batavia or Malacca, of which there are three sorts, the one being extracted from the cocoa-tree, the second from rice, and the third from sugar: but the first is the best and most in use. It is made of the blossom-bunch of the cocoa-tree: for which purpose they tie the bunch, while it is still wrapped up within its cod, or membrane, with a piece of packthread; and then with a knife make a cross cut in that bunch, a little above the place where it is tied, and adapt a pitcher to it to receive the liquor, which is called toddy, and is vinous, palatable, and sweet: others use a bamboo-cane instead of a pitcher. Having thus drawn the liquor, they let it ferment, and afterwards distill it.

To **RACK** *winers*, &c. to draw them off from their lees, after their having stood long enough to clear and settle.

Hence rack-vintage is frequently used for the second voyage our wine-merchants used to make into France for racked-wines.

RACKOON, in zoology. See **VIVERRA**.

RADIALIS, in anatomy. See **ANATOMY**, p. 198.

RADIANT, in optics, is any point of a visible object from whence rays proceed. See **OPTICS**.

RADIATED *flowers*, in botany, are such as have several semi-bolcules set round a disk, in form of a radiant star; those which have no such rays are called discous flowers.

RADIATION, the act of a body emitting or diffusing rays of light all round, as from a centre. See **OPTICS**.

RADICAL, in general, something that serves as a basis or foundation.

Hence physicians talk much of a radical moisture.

In grammar, we give the appellation radical to primitive words, in contradistinction to compounds and derivatives.

Algebraists also speak of the radical sign of quantities, which is the character expressing their roots.

RADICLE, that part of the seeds of all plants, which upon vegetating becomes its root, and is discoverable by the microscope. See **AGRICULTURE**, p. 41.

RADISH, in botany. See **RAPHANUS**.

RADIUS, in geometry, the semi-diameter of a circle, or a right line drawn from the centre to the circumference.

RADIUS, in anatomy. See **ANATOMY**, p. 179.

RADIX. See **ROOT**.

RADNOR, the capital of the county of Radnor in Wales, situated in W. long. 3° 6', N. lat. 52° 20'.

RAFTERS, in building, are pieces of timber, which standing by pairs on the rafters or raising piece, meet in an angle at the top, and form the roof of a building. See **ARCHITECTURE**.

RAGOUT, a sauce, or seasoning, intended to rouse the appetite when lost or languishing.

RAGULED, or **RAGGED**, in heraldry, jagged or knotted. This term is applied to a cross formed of the trunks of two trees without their branches, of which they shew only the stumps. See **Plate CXLVII** fig. 5.

Raguled differs from indented, in that the latter is regular, the former not.

RAJA, the title of the Indian black princes, the remains of those who ruled there before the Moguls. Some of the rajas are said to preserve their independency, especially in the mountainous parts; but most of them pay an annual tribute to the Mogul.

RAJA, in ichthyology, a genus belonging to the order of amphibia nantes. There are five spiracula below towards the peak; the body is compressed; and the mouth is situate under the head. There are nine species, one of which is the torpedo, or cramp-fish, found in the Mediterranean and Persian Gulph. When touched, it defends itself by a tremulous motion, which benumbs any animal which attempts to injure it.

RAJANIA, in botany, a genus of the diœcia hexandria class. The calix of both male and female consists of six segments; none of them have any corolla: the female has three styl; the fruit is roundish, with an oblique wing. There are three species, none of them natives of Britain.

RAIL, in ornithology. See **RALLUS**.

RAIN, water which descends from the clouds in form of drops of water.

Rain is apparently the precipitated vapours of watery clouds: thus, when various congeries of clouds are driven together by the agitation of the winds, they mix and run into one body, and by that means dissolve and condense each other into their former substance of water: also the coldness of the air is a great means to collect, compact, and condense clouds into water; which being heavier than the air, must of necessity fall through it in the form we call rain. Now the reason why it falls in drops, and not in whole quantities, as it becomes condensed, is the resistance of the air; whereby being broken, and divided into smaller and smaller parts the farther it passes through the air, it at last arrives to us in small drops.

Mr. Derham accounts for the precipitation hence, that the vesiculæ being full of air, when they meet with a colder air than that they contain, their air is contracted into a less space; and consequently the watery shell rendered thicker, so as to become heavier than the air, &c.

Others only allow the cold a part in the action, and bring in the winds as sharers with it: indeed, it is plain, that a wind, blowing against a cloud, will drive its vesiculæ upon one another, by which means several of them coalescing, will be enabled to descend; and the effect will be still more considerable if two opposite winds blow towards the same place. Add to this, that clouds already formed, happening to be aggravated by fresh accessions of vapour continually ascending, may thence be enabled to descend.

According to Rohault, the great cause of rain is the heat of the air; which, after continuing for some time near the earth, is at length carried up on high by a wind, and there thawing the snowy villi, or flocks of the half frozen vesiculæ, reduces them into drops; which, coalescing, descend.

Others, as Dr. Clarke, &c. ascribe this descent of the clouds rather to an alteration of the atmosphere than of the vesiculæ; and suppose it to arise from a diminution of the elastic force of the air. This elasticity, which depends chiefly or wholly on the terrene exhalations, being weakened, the atmosphere sinks under its burden, and the clouds fall.

Now the little vesicles, being once upon the descent, will persist therein, notwithstanding the increase of resistance they every moment meet with. For as they all tend toward the centre of the earth, the farther they fall, the more coalitions will they make; and the more coalitions, the more matter will there be under the same surface; the surface only increasing as the squares, but the solidity as the cubes; and the more matter under the same surface, the less resistance there will be to the same matter. Thus, if the cold, wind, &c. act early enough to precipitate the ascending vesicles, before they are arrived at any considerable height, the coalitions being but few, the drops will be proportionably small; and thus is formed a dew. If the vapours be more copious, and rise a little higher, we have a mist or fog. A little higher still, and they produce a small rain, &c. If they neither meet with cold nor wind, they form a heavy, thick, dark sky.

Hence, many of the phenomena of the weather may be accounted for: as, why a cold summer is always a wet one, and a warm a dry one; why we have commonly most rain about the equinoxes; why a settled, thick, close sky scarce ever rains, till it have been first clear. As to the quantity of rain that falls, its proportion in several places at the same time, and in the same place at several times, we have store of observations, journals, &c. in the memoirs of the French Academy, Philosophical Transactions, &c.

RAIN-BOW. See *OPTICS*, p. 439, &c.

Lunar RAIN-BOW. The moon sometimes also exhibits the phenomenon of an iris, by the refraction of her rays in drops of rain in the night-time.

Aristotle says, he was the first that ever observed it; and adds, that it is never visible but at the time of full moon.

The lunar iris has all the colours of the solar, only fainter.

Marine RAIN-BOW, the sea-bow, is a phenomenon sometimes observed in a much agitated sea, when the wind, sweeping part of the tops of the waves, carries them aloft; so that the rays of the sun are refracted, &c. as in a common shower.

RAISINS, grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven. The difference between raisins dried in the sun, and those dried in ovens, is very obvious: the former are sweet and pleasant, but the latter have a latent acidity with the sweetness that renders them much less agreeable.

RAKE of a ship is all that part of her hull which hangs over both ends of her keel. That which is before, is called the fore-rake, or rake-forward; and that part which is at the setting on of the stern-post, is called the rake aft, or afterward.

RALLUS, in ornithology, a genus belonging to the order of grallæ. The beak is thickest at the base, compressed, equal, acute, and somewhat sharp on the back near the point: the nostrils are oval; the feet have four toes, without any web; and the body is compressed. There are ten species, principally distinguished by their colour.

RAM, in zoology. See *OVIS*.

RAM, in astronomy. See *ASTRONOMY*.

Battering RAM, in antiquity, a military engine used to batter and beat down the walls of places besieged.

The battering ram was of two sorts; the one rude and plain, the other compound. The former seems to have been no more than a great beam which the soldiers bore on their arms and shoulders, and with one end of it by main force assailed the wall. The compound ram is thus described by Josephus: it is a vast beam, like the mast of a ship, strengthened at one end with a head of iron, something resembling that of a ram, whence it took its name.

This was hung by the middle with ropes to another beam, which lay across two posts; and hanging thus equally balanced, it was by a great number of men drawn backwards and pushed forwards, striking the wall with its iron-head.

Plutarch informs us, that Marc Anthony, in the Parthian war, made use of a ram fourscore feet long; and Vitruvius tells us that they were sometimes an hundred and six, and sometimes an hundred and twenty feet in length; and to this perhaps the force and strength of the engine was in a great measure owing. The ram was managed at one time by a whole century of soldiers; and they being spent, were succeeded by another century, so that it played continually without any intermission.

RAM's HEAD, in a ship, is a great block belonging to the fore and main halliards. It has three shivers in it, into which the halliards are put, and in a hole at the end of it are reeved the ties.

RAMADAN, a solemn season of fasting among the Mahometans. See *MAHOMETANISM*.

RAMIFICATION, the production of boughs or branches, or of figures resembling branches.

RAMMER, an instrument used for driving down stones or piles into the ground; or for beating the earth, in order to render it more solid for a foundation.

RAMMER of a gun, the gun-stick; a rod used in charging of a gun, to drive home the powder, as also the flint and the

- the wad, which keeps the shot from rolling out. See GUNNERY.
- RAMPANT**, in heraldry, a term applied to a lion, leopard, or other beast that stands on his hind-legs, and rears up his forefeet in the posture of climbing, shewing only half his face, as one eye, &c. It is different from salient, in which the beast seems springing forward as if making a fall. See Plate CXLVII fig. 6.
- RAMPART**, in fortification, is an elevation of earth round a place capable of resisting the cannon of an enemy; and formed into bastions, curtains, &c. See FORTIFICATION.
- RAMSEY**, an island in the Irish channel, on the coast of Pembrokehire: W. long $5^{\circ} 20'$, N. lat. $51^{\circ} 55'$.
- RAMUS**, in general, denotes a branch of any thing, as of a tree, an artery, vein, &c.
- RANA**, the FROG, in zoology, a genus belonging to the class of amphibia reptilia. The body is naked, furnished with four feet, and without any tail. There are 17 species. Frogs undergo a very strange metamorphosis. When they first issue from the eggs, they appear in a roundish form, with a long tail, and are then denominated tadpols. After continuing in this state for several weeks, the tail begins to mortify and fall off gradually, the feet at the same time springing as gradually out of the body, till they assume the complete form of frogs.
- RANCHIERA**, a port-town of Terra Firma, situated in W. long. 72° , N. lat. $11^{\circ} 34'$.
- RANCID**, denotes a fatty substance that is become rank or musty, or has contracted an ill smell by being kept close.
- RANGE**, in gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges. See GUNNERY.
- RANGIFER**, the RAIN-DEER. See CORVUS.
- RANK**, the order or place allotted a person, suitable to his quality or merit.
- RANKING OF CREDITORS**, in Scots law. See LAW, Tit. XIX. 13.
- RANSOM** a sum of money paid for the redemption of a slave, or for the liberty of a prisoner of war. In our law-books, ransom is also used for a sum paid for the pardon of some great offence, and to obtain the offender's liberty.
- RANULA**, a tumour under the tongue, which like a ligature hinders a child from speaking or sucking.
- RANUNCULUS**, in botany, a genus of the polyandria polygynia class. The calix consists of five leaves, and the corolla of five petals, with a melliferous pore in the claw of each; and the seeds are naked. There are 38 species, 11 of them natives of Britain.
- RAOLCONDA**, a city of the hither India, situated in the province of Golconda: E. long. 79° , N. lat. $19^{\circ} 12'$.
- RAPACIOUS ANIMALS**, are such as live upon prey.
- RAPE**, in law, the having carnal knowledge of a woman by force and against her will. See LAW, Tit. xxxiii. 26.
- RAPHANUS**, in botany, a genus of the tetradynamia siliquosa class. The calix is shut; the pod is cylindrical, and subarticulated; there are two melliferous glands between the short stamina and the pistillum, and as many between the long stamina and calix. There are three species, only one of them, viz. the raphanistrum, charlock, a native of Britain.
- RAPHIDIA**, in zoology, a genus of insects belonging to the order of neuroptera. The head is depressed and horny; it has two teeth, four pappi, and three stemmata; the wings are deflexed; the feelers are cylindrical, and of the length of the thorax; and the tail of the female is furnished with a lax bended bristle. There are three species.
- RAPIER**, formerly signified a long old-fashioned broad sword, such as those worn by the common soldiers: but it now denotes a small sword, as contradistinguished from a back-sword.
- RAPINE**, in law, the taking away another's goods, &c. openly and by violence.
- RAPPAHANOCK**, a large navigable river which rises in the mountains west of Virginia, and discharges itself into the bay of Chesapeake.
- RAPTURE**, an ecstacy, or transport of mind. See ECSTASY.
- RARE**, in physics, stands opposed to dense; and denotes a body that is very porous, whose parts are at a great distance from one another, and which contains but little matter under a large bulk.
- RAREFACTION**, in physics, the act whereby a body is rendered rare; that is, brought to possess more room, or appear under a larger bulk without accession of any new matter.
- RASEBURG**, a port town of Sweden, in the province of Finland, and territory of Nyland, situated on the gulph of Finland: E. long. 23° , N. lat. $60^{\circ} 22'$.
- RASTAT**, the name of two towns of Germany: one in the circle of Bavaria and archbishopric of Saltzburg, situated on the river Ens, thirty-five miles south of the city Ens; another in the circle of Swabia and marquisate of Baden, situated on the east side of the river Rhine, twenty-one miles south west of Philipsburg.
- RAT**, in zoology. See MUS.
- RAT-TAILS, or ARRESTS**, in the manege, signify hard callous swellings upon the hinder legs under the hough, running along the sinew.
- A horse is called rat-tail, when he has no hair upon his tail.
- RATAFIA**, a fine spirituous liquor, prepared from the kernels, &c. of several kinds of fruits, particularly of cherries and apricots.
- Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has been long kept; then adding to them the kernels of cherries, with straw-berries, sugar, cinnamon, white pepper, nutmeg, cloves; and to twenty pound of cherries, ten quarts of brandy. The vessel is left open ten or twelve days, and then stopp'd close for two months before it be tapped. Ratafia of apricots is prepared two ways, viz. either by oiling the apricots in white-wine, adding to the liquor an equal quantity of brandy, with sugar, cinnamon, mace, and the kernels of apricots; infusing the whole for eight or ten days; then straining the liquor, and putting it up for use: Or else by int. sing the apricots cut in pieces in brandy, for a day or two, passing it through a straining bag, and then putting in the usual ingredients.
- RATCH**, or RASH, in clock-work, a sort of wheel having twelve fangs, which serve to lift up the detent every hour, and make the clock strike. See WATCH.
- RATCHETS**, in a watch, are the small teeth at the bot-

tom of the fufy, or barrel, which ftops it in winding up.
RATE, a ftandard or proportion, by which either the quantity or value of a thing is adjusted.

RATE of a *ſhip of war*, is its order, degree, or diſtinction, as to magnitude, burden, &c.

RATEEN, in commerce, a thick woollen ſtuff, quilted, woven on a loom with four treddles, like ſerges, and other ſtuffs, that have the whale or quilting. There are ſome rateens dreſſed and prepared like cloths; others left ſimply in the hair; and others where the hair or knap is frized. Rateens are chiefly manufactured in France, Holland, and Italy, and are moſtly uſed in linings. The frize is a fort of coarſe rateen, and the drugget is a rateen half linnen half woollen.

RATIFICATION, an act approving off, and confirming ſomething done by another in our name.

RATIO, in arithmetic and geometry, is that relation of homogeneous things which determines the quantity of one from the quantity of another, without the intervention of a third. See **ARITHMETICK**, **ALGEBRA**, and **GEOMETRY**.

RATIOCINATION, the act of reaſoning. See **REASONING**.

RATION, in the army, a portion of ammunition, bread, drink, and forage, diſtributed to each ſoldier in the army, for his daily ſubſiſtence. &c. The horſe have rations of hay and oats, when they cannot go out to forage. The rations of bread are regulated by weight. The ordinary ration of a foot-ſoldier is a pound and a half of bread per day. The officers have ſeveral rations according to their quality and the number of attendants that they are obliged to keep. When the ration is augmented on occaſions of rejoicing, it is called a double ration. The ſhips crews have alſo their rations or allowances of biſcuit, pulſe, and water, proportioned according to their ſtock.

RATIONAL, *reaſonable*. See **REASON**.

RATIONAL, is alſo applied to integral, fractional, and mixt numbers: thus we ſay rational fraction, rational integer, and rational mixt number.

RATIONALE, a ſolution or account of the principles of ſome opinion, action, hypotheſis, phenomenon, or the like.

RATIPOR, a town of Bohemia, in the duchy of Sileſia, ſituated on the river Oder; ſixteen miles north-eaſt of Tropolaw.

RATIPOR, is alſo a city of hither India, capital of the province of Malva, ſituated E. long. 80°, N. lat. 25°.

RATISBON, a city of Germany, in the circle of Bavaria, ſituated at the confluence of the rivers Danube and Regen, in E. long. 12° 5', N. lat. 49°. This is a free imperial city, and here the aſſembly or diet of the ſtates of the empire meets.

RATLINES, or, as the ſeamen call them, **RATLINS**, thoſe lines which make the ladder ſteps to go up the ſhrouds and putlocks, hence called the ratlins of the ſhrouds.

RATTLE SNAKE, See **CROTALUS**.

RATTLE-SNAKE ROOT. See **POLYGALA**.

RAVA, a city of Great Poland, capital of the Palatinate of Rava. ſituated fifty miles ſouth-eaſt of Warſaw.

RAVELIN, in fortification, was anciently a flat baſtion, placed in the middle of a curtain; but now a detached work compoſed only of two faces, which make a ſalient

angle, without any flanks, and raiſed before the curtain on the counterſcarp of the place. See **FORTIFICATION**.

RAVEN, in ornithology. See **CORVUS**.

RAVENGLAS, a port-town of Cumberland, ſituated on the Iriſh Channel, thirty-eight miles ſouth-weſt of Carlisle.

RAVENNA, a city of Italy, in the pope's territories, capital of the province of Romania, ſituated E. lon. 13°, N. lat. 44° 30'.

RAUVOLFA, in botany, a genus of the pentandria monogynia claſs. The berry contains two ſeeds. There are two ſpecies, both natives of America.

RAY, in optics, a beam of light, emitted from a radiant or luminous body. See **OPTICS**.

RAYLEIGH, a market-town of Eſſex, ten miles ſouth-eaſt of Chelmsford.

RAYONANT, or *Groſs* **RAYONANT**, in heraldry, one which has rays of glory behind it, darting out from the centre to all the quarters of the eſcutcheon, as repreſented in Plate CXLVII. fig. 7.

RAZOR, a well known inſtrument uſed by ſurgeons, barbers, &c. for ſhaving off the hair from various parts of the body.

RAZOR-BILL, in ornithology. See **ALCA**.

RE-ACTION, in phyſiology, the reſiſtance made by all bodies to the action or impulſe of others that endeavour to change its ſtate whether of motion or reſt. See **MCHANICS**.

READING, a borough town in Berkſhire, ſituated forty miles weſt of London, near the confluence of the river Kenet and Thames; it ſends two members to parliament.

REAL, is applied to a being that actually exiſts; in which ſenſe, it coincides with actual.

REAL, or **CHIAPA**, a city of Mexico, in North America, capital of the province of Chiapa, ſituated W. lon. 97°, N. lat. 17°.

REALEIO, a port-town of Mexico, in the province of Nicaragua, ſituated on the bay of the Pacific Ocean, in W. long. 91° 30', N. lat. 12°.

REALISTS, a ſect of ſchool philoſophers, formed in oppoſition to the nominaliſts. See **NOMINALISTS**.

Under the Realists are included the Scotiſts, Thomiſts, and all excepting the followers of Ocham. Their diſtinguiſhing tenet is, that univerſals are realities, and have an actual exiſtence out of an idea or imagination, or, as they expreſs it in the ſchools, a *parte rei*: whereas the nominaliſts contend, that they exiſt only in the mind, and are only ideas, or manners of conceiving things.

REALITY, in the ſchools, a diminutive of *res*, thing, firſt uſed by the Scotiſts, to denote a thing which may exiſt of itſelf; or which has a full and abſolute being of itſelf, and is not conſidered as a part of any other.

REALM, a country which gives its head, or governor, the denomination of a king.

REALMONT, a town of France, in the province of Languedoc, ſituated thirty-two miles north-eaſt of Thoulouſe.

REAR, a term frequently uſed in compoſition, to denote ſomething behind, or backwards, in reſpect of another, in oppoſition to van: thus, in a military ſenſe, it is uſed for the hind part of an army, in oppoſition to the front.

REASON, a faculty or power of the mind, whereby it diſtin-

distinguishes good from evil, truth from falsehood, &c. See LOGIC and METAPHYSICS.

REASONING, RATIOCINATION, the exercise of the faculty of the mind called reason; or it is an act or operation of the mind, deducing some unknown proposition from other previous ones that are evident and known. See LOGIC, and METAPHYSICS.

REBATE, or REBATEMENT, in commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer instead of taking time advances ready money.

REBATEMENT, in heraldry, a diminution or abatement of the bearings in a coat of arms.

REBEL, a town of Germany, in the duchy of Meissen; burgh, thirty-two miles south-east of Gultrow.

REBELLION, a traitorous taking up of arms against the king by his own natural subjects, or those formerly subdued.

REBUS, in ænigmatical representation of some name, &c. by using figures or pictures instead of words, or parts of words. Camden mentions an instance of this absurd kind of wit in a gallant, who expressed his love to a woman, named Rose Hill, by painting in the border of his gown a *rose*, a *hill*, an *eye*, a *leaf*, and a *well*; which, in the style of the rebus, reads, *Rose Hill, I love well*. This kind of wit was long practised by the great, who took the pains to find devices for their names. It was, however, happily ridiculed by Ben Johnson, in the humorous description of Abel Druggers device, in the Alchemist; and by the Spectator, in the device of Jack of Newberry; at which time the rebus, being raised to sign-posts, was grown out of fashion at court.

REBUTTER, in law, the defendant's answer to the plaintiff's surrejoinder, in a cause depending in the court of chancery, &c.

RECAPITULATION, is a summary, or a concise and transient enumeration of the principal things insisted on in the preceding discourse, whereby the force of the whole is collected into one view.

RECEIVER, in pneumatics, a glass-vessel for containing the thing on which an experiment in the air-pump is to be made. See PNEUMATICS.

RECEPTACULUM CHYLI. See ANATOMY, p. 282.

RECHABITES, a kind of religious order among the ancient Jews, instituted by Jonadab the son of Rechab, comprehending only his own family and posterity.

Their founder prescribed them three things: first, not to drink any wine; secondly, not to build any houses, but to dwell in tents; and thirdly, not to sow any corn, or plant vines. These rules the Rechabites observed with great strictness.

RECIPE, in medicine, a prescription or remedy, to be taken by a patient; so called because always beginning with the word *recipe*, i. e. *take*; which is generally denoted by the abbreviation R.

RECIPIENT, the same with receiver.

RECIPROCAL, in general, something that is mutual, or which is returned equally on both sides, or that affects both parties alike.

RECIPROCAL TERMS, among logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

RECIPROCAL FIGURES, in geometry, those which have

the antecedents and consequents of the same ratio in both figures. See GEOMETRY.

RECITATIVO, in music, a kind of singing that differs but little from ordinary pronunciation, such as that in which the several parts of the liturgy are rehearsed in cathedrals; or that wherein the actors commonly deliver themselves on the theatre at the opera, when they are to express some action or passion, to relate some event, or reveal some design.

RECKONING, or a ship's RECKONING. See NAVIGATION.

RECLINATION of a plane, in dialling, the number of degrees which a dial-plane leans backwards from an exactly upright or vertical plane, that is, from the zenith. See DIALLING.

RECLUSE, among the Papists, a person shut up in a small cell of an hermitage, or monastery, and cut off, not only from all conversation with the world, but even with the house. This is a kind of voluntary imprisonment, from a motive either of devotion or penance.

RECOLLECTION, a mode of thinking, by which ideas sought after by the mind, are found, and brought again to view.

RECONNOITRE, in war, to view and examine the state and situation of things.

RECORD, an authentic testimony in writing, contained in rolls of parchment, and preserved in a court of record.

RECORDER, a person whom the mayor and other magistrates of a city or corporation associate to them, for their better direction in matters of justice, and proceedings in law; on which account this person is generally a counsellor, or other person well skilled in the law.

The recorder of London is chosen by the lord mayor and aldermen; and, as he is held to be the mouth of the city, he delivers the judgment of the courts therein, and records and certifies the city-customs.

RECOURSE ON BILLS, in Scots law. See LAW, Tit. XXI, 12.

RECREMENT, in chemistry, some superfluous matter separated from some other that is useful: in which sense it is the same with scoria, feces, and excrements. See CHEMISTRY.

RECRIMINATION, in law, an accusation brought by the accused against the accuser upon the same fact.

RECRUITS, in military affairs, new-raised soldiers, designed to supply the place of those who have lost their lives in the service, or are disabled by age or wounds.

RECTANGLE, in geometry, the same with a right-angled parallelogram. See GEOMETRY.

RECTIFICATION, in chemistry, is nothing but the repetition of a distillation or sublimation several times, in order to render the substance purer, finer, and freer from aqueous or earthy parts.

RECTIFIER, in navigation, an instrument consisting of two parts, which are two circles either laid one upon, or let into, the other, and so fastened together in their centres, that they represent two compasses, one fixed, the other moveable; each of them divided into the thirty-two points of the compass, and three hundred and sixty degrees, and numbered both ways, from the north and the south, ending at the east and west, in ninety degrees.

The fixed compass represents the horizon, in which the

the north and all the other points of the compass are fixed and immovable.

The moveable compass represents the mariners compass, in which the north and all other points are liable to variation.

In the centre of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compass. But, if the instrument be made of wood, there is an index instead of the thread.

Its use is to find the variation of the compass, to rectify the course at sea; having the amplitude or azimuth given.

RECTIFIER, in the distillery, the person whose employment it is to take the coarse malt-spirit of the malt-stiller, and redistil it to a finer and better liquor.

RECTILINEAR, in geometry, right-lined : thus figures whose perimeter consists of right lines, are said to be rectilinear.

RECTITUDE, in philosophy, refers either to the act of judging or of willing : and therefore whatever comes under the denomination of rectitude is either what is true, or what is good ; these being the only objects about which the mind exercises its two faculties of judging and willing.

Moral rectitude, or uprightness, is the chusing and pursuing those things which the mind, upon due inquiry and attention, clearly perceives to be good ; and avoiding those that are evil.

RECTOR, a term applied to several persons whose offices are very different : as, 1. The rector of a parish is a clergyman that has the charge and cure of a parish, and possesses all the tythes, &c. 2. The same name is also given to the chief elective officer in several foreign universities, particularly in that of Paris. 3. Rector is also used in several convents for the superior officer who governs the house : and the Jesuits give this name to the superiors of such of their houses as are either seminaries or colleges.

RECTORY, a parish-church, parsonage, or spiritual living, with all its rights, tythes, and glebes.

RECTUM, in anatomy, the third and last of the large intestines or guts. See **ANATOMY**, p. 261.

RECTUS, in anatomy, a name common to several pair of muscles, so called on account of the straightness of their fibres. See **ANATOMY**, Part II.

RECURRENTS, in anatomy, a name given to several large branches of nerves sent out by the par vagum from the upper part of the thorax to the larynx.

RECURVIROSTRA, in ornithology, a genus belonging to the order of grallæ. The beak is subulated, bent back, sharp and flexible at the point ; the feet are webbed, and furnished with three toes. There is but one species, viz. the avocetta, a native of the southern parts of Europe. It migrates into Italy, but seldom to the north.

RECUSANTS, such persons as acknowledge the pope to be the supreme head of the church, and refuse to acknowledge the king's supremacy ; who are hence called popish recusants. These are in England charged with double taxes, not merely as Romanists but as recusants.

RED, one of the simple or primary colours of natural bodies, or rather of the rays of light. See **OPTICS**.

RED, in dying, is one of the five simple or mother colours. Some reckon six kinds or calls of red, viz. scarlet red,

crimson red, madder red, half-grain red, lively orange red, and scarlet or cochineal : but they may be all reduced to the three following, according to the three principal drugs which give the colours, viz. the kermes, cochineal, and madder.

RED, in heraldry. See **GULES**.

RED RUSSIA, or **LITTLE RUSSIA**, a province of Poland, bounded by the province of Polesia, on the north ; by Volhina and Podolia on the east ; by the Carpathian mountains, which divide it from Transilvania and Hungary, on the south ; and by the province of Little Poland, on the west ; being two hundred miles long, and one hundred broad.

RED-SEA separates Asia from Africa.

REDDLE, a soft, heavy, red marle, of great use in colouring ; and being washed and freed from its sand, is often sold by our druggists under the name of bole-armenic.

REDEMPTION, in law, a faculty or right of re-entering upon lands, &c. that have been sold and assigned, upon reimbursing the purchase-money with legal costs.

REDENS, in fortification, a kind of work indented in form of the teeth of a saw, with salient and re-entering angles, to the end that one part may flank or defend another. It is called saw-work and indented-work.

REDTEGRATION, in the civil law, the act of restoring a person to the enjoyment of a thing whereof he had been illegally dispossessed.

REDOUBT, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach ; as also for the lodgings of corps de gard, and to defend passages.

REDRESSING, the rectifying or setting any thing straight again.

In a moral sense, to redress grievances is to reform and remove them.

To redress a stag, among hunters, is to put him off his chases.

REDRUTH, a market-town of Cornwall, situated fifty miles south west of Launceston.

REDUBBORS, those who buy stolen cloaths, &c. and, to the end they may not be known, convert them into some other form, or change the colour, &c.

REDUCTION, in the schools, a manner of bringing a term or proposition, which was before opposite to some other, to be equivalent to it.

REDUCTION, in arithmetic. See **ARITHMETICK**, p. 380.

REDUCTION, in surgery, denotes an operation whereby a dislocated, luxated, or fractured bone is restored to its former state or place.

REDUCTION, in Scots law. See **LAW**, Tit. xxx. 3.

REDUNDANCY, a fault in discourse, consisting in the use of a superfluity of words. Words perfectly synonymous are redundant, and ought to be retrenched.

REED, in botany. See **ARUNDO**.

REEF, a term in navigation. When there is a great gale of wind, they commonly roll up part of the sail below, that by this means it may become the narrower, and not draw so much wind ; which contracting or taking up the sail, they call a reef, or reefing the sail : so also when a top-mast is sprung, as they call it, that is, when it is cracked, or almost broken in the cap, they cut off the lower piece that was near broken off, and setting the other

part,

part, now much shorter, in the sleep again, they call it a reefed top-mast.

REEL, in the manufactories, a machine serving for the office of reeling. There are various kinds of reels, some very simple, others very complex.

REELING, in the manufactories, the winding of thread, silk, cotton, or the like, into a skein, or upon a bottom, to prevent its entangling. It is also used for the charging or discharging of bobbins or quills, to use them in the manufacture of different stuffs, as thread, silk, cotton, &c. Reeling is performed different ways, and on different engines.

REEVING, in the sea language, the putting a rope through a block: hence to pull a rope out of a block, is called unreeving.

RE-EXCHANGE, in commerce, a second payment of the price of exchange, or rather the price of a new exchange due upon a bill of exchange that comes to be protested and to be refunded the bearer by the drawer or indorser.

REFECTION, among ecclesiastics, a spare meal or repast, just sufficing for the support of life: hence the hall in convents, and other communities, where the monks, nuns, &c. take their refectiōns or meals in common, is called the refectory.

REFERENCE, in writing, &c. a mark relative to another similar one in the margin, or at the bottom of the page, where something omitted in the text is added, and which is to be inserted either in reading or copying.

REFINING, in general, is the art of purifying a thing; including not only the sifting or refining of metals, but likewise the clarification of liquors.

REFINING of gold. See **CHEMISTRY**, p. 129.

REFINING of silver. See **CHEMISTRY**, p. 130.

REFLECTION, the return or regressive motion of a moving body, occasioned by some obstacle which hindered it from pursuing its former direction.

REFLECTION of the rays of light. See **OPTICS**.

REFLECTION is also used, figuratively, for an operation of the mind; whereby it turns its view backwards as it were upon itself, and makes itself and its own operation the object of its disquisition; and by contemplating the manner, order, and laws which it observes in perceiving ideas, comparing them together, reasoning, &c. it frames new ideas of the relations discovered therein. See **LOGIC**, and **METAPHYSICS**.

REFLUX of the sea, the ebbing of the water, or its returning from the shore. See **ASTRONOMY**, p. 473.

REFORMATION, the act of reforming or correcting an error or abuse in religion, discipline, or the like.

The Reformation, so called by way of eminence, is the separation of the Protestants from the church of Rome, in the beginning and towards the middle of the sixteenth century.

REFRACTION, in general, is the deviation of a moving body from its direct course, occasioned by the different density of the medium it moves in; or it is a change of direction, occasioned by a body's falling obliquely out of one medium into another of a different density. See **OPTICS**.

REFRANGIBILITY of light, the disposition of rays to be refracted. See **OPTICS**.

REFRIGERATIVE, in medicine, a remedy which re-

freshes the inward parts, by cooling them, as clysters, pifans, &c.

REFRIGERATORY, in chemistry, a vessel filled with cold water, through which the worm passes in distillations; the use of which is, to condense the vapours as they pass through the worm.

REFUGE, a sanctuary or asylum.

REFUGEES, French Protestants; who, by the revocation of the edict of Nantz, have been constrained to fly from persecution, and take refuge in foreign countries.

REGAL or **ROYAL**, something belonging to a king.

REGALE, a magnificent entertainment or treat given to ambassadors, and other persons of distinction, to entertain or do them honour.

It is usual, in Italy, at the arrival of a traveller of eminence, to send him a regale that is, a present of sweetmeats, fruit, &c. by way of refreshment.

REGALE, in the French jurisprudence, is a royal prerogative, which consists in enjoying the revenues of bishoprics during the vacancy of their sees, of presenting to benefices, and of obliking the new bishop to take an oath of fidelity, and to register it in the chamber of accounts. The enjoyment of the fruits of the see is called the temporal regale; and that of presenting to the see, the spiritual regale.

REGALIA, in law, the rights and prerogatives of a king; which, according to civilians, are six: *viz.* 1. The power of judicature: 2. The power of life and death: 3. The power of peace and war: 4. A right to such goods as have no owner, as waifs, estrays, &c. 5. Adfinescents: and, 6. The coinage of money.

Regalia is also used for the apparatus of a coronation, as the crown, the sceptre with the cross, that with the dove, St. Edward's staff, the globe, and the orb with the cross, four several swords, &c.

REGALIA, in Scots law. See **LAW**, Tit. xiii. 3.

Lord of REGALITY, in Scots law. See **LAW**, Tit. iv. 4.

REGARDANT, in heraldry, signifies looking behind; and is used for a lion, or other beast, with his face turned towards his tail.

REGARDER, an ancient officer of the king's forest, sworn to make the regard of the forest every year; that is, to take a view of its limits, to inquire into all offences and defaults committed by the foresters within the forest, and to observe whether all the other officers executed their respective duties.

REGEL, or **RIGEL**, a fixed star of the first magnitude, in Orion's left foot.

REGENERATION, in theology, the act of being born again by a spiritual birth, or the change of heart and life experienced by a person who forsakes a course of vice, and sincerely embraces a life of virtue and piety.

REGENT, one who governs a kingdom during the minority or absence of the king.

In France, the queen-mother has the regency of the kingdom during the minority of the king, under the title of queen-regent.

REGENT also signifies a professor of arts and sciences in a college, who has a set of pupils under his care; but here regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c. those of philosophy are rather called professors.

REGICIDE, KING-KILLER, a word chiefly used with us in speaking of the persons concerned in the trial, condemnation, and execution of king Charles I.

REGIFUGE, a feast celebrated in ancient Rome on the sixth of the kalends of March, in memory of the expulsion of their ancient kings, and particularly of Tarquin's flying out of Rome on that day.

REGIMEN, the regulation of diet, and, in a more general sense, of all the non-naturals, with a view to preserve or restore health. See **MEDICINE**.

REGIMEN, in grammar, that part of syntax, or construction, which regulates the dependency of words, and the alterations which one occasions in another. See **GRAMMAR**.

REGIMENT, in war, is a body of men, either horse or foot, commanded by a colonel.

Each regiment of foot is divided into companies; but the number of companies is not always alike; though our regiments generally consist of thirteen companies, one of which is always grenadiers.

Regiments of horse most commonly consist of six troops, but some have nine.

Regiments of dragoons, in time of war, are generally composed of eight troops; and in time of peace, of six.

REGION, in geography, a large extent of land, inhabited by many people of the same nation, and inclosed within certain limits or bounds.

REGISTER, a public book in which is entered and recorded memoirs, acts, and minutes, to be had recourse to occasionally, for knowing and proving matters of fact.

REGISTER SHIPS, in-commerce, are vessels which obtain a permission either from the king of Spain, or the council of the Indies, to traffic in the ports of the Spanish West-Indies; which are thus called, from their being registered before they set sail from Cadiz, for Buenos Ayres.

REGISTERS, in chemistry, are holes, or chimneys with stopples, contrived in the sides of furnaces, to regulate the fire; that is, to make the heat more intense, or remiss, by opening them to let in the air, or keeping them close to exclude it.

REGISTRY, the office, books, and rolls, in which the proceedings in chancery, or any spiritual court, are registered.

REGRATOR, or **REGRATER**, in law, formerly signified one who bought wholesale, or by the great, and sold again by retail: but the term is now used for one who buys any wares or victuals, and sells them again in the same market, or fair, or within fifteen miles round it. See **FORESTALLING**.

REGULAR, denotes any thing that is agreeable to the rules of art: thus, we say a regular building, verb, &c.

A regular figure, in geometry, is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides, is commonly termed an equilateral triangle, or square; as all others with more sides are called regular polygons.

REGULAR, in a monastery, a person who has taken the vows; because he is bound to observe the rules of the order he has embraced.

REGULATION, a rule or order prescribed by a superior, for the proper management of some affair.

REGULATOR of a watch, the small spring belonging to

the balance; serving to adjust its motions, and make it go faster or slower. See **WATCH**.

REGULUS, in ornithology. See **MOTACILLA**.

REGULUS, in chemistry, an imperfect metallic substance, that falls to the bottom of the crucible, in the melting of ores or impure metallic substances. See **CHEMISTRY**, *passim*.

REHABILITATION, in the civil and the canon law, the restoring a delinquent to his former condition.

REHEARSAL, in music and the drama, an essay or experiment of some composition, generally made in private, previous to its representation or performance in public, in order to render the actors and performers more perfect in their parts.

REIN-DEER, in zoology. See **CERVUS**.

REINS, in anatomy. See **ANATOMY**, p. 268.

REJOINDER, in law, is the defendant's answer to the plaintiff's replication or reply. Thus, in the court of chancery, the defendant puts in an answer to the plaintiff's bill, which is sometimes also called an exception; the plaintiff's answer to this is called a replication; and the defendant's answer to that a rejoinder.

REITERATION, the act of repeating a thing, or doing it a second time.

RELAPSE, a falling again into a danger, evil, or disease, from which a person has escaped.

RELATION, the mutual respect of two things, or what each is with regard to the other. See **METAPHYSICS**.

RELATION, in geometry. See **RATIO**.

RELATION is also used for analogy. See **ANALOGY**.

RELATIVE, something relating to, or respecting, another.

RELATIVE TERMS, in logic, are words which imply a relation: such are master and servant, husband and wife, &c.

RELAXATION, in medicine, &c. the act of loosening or slackening, or the looseness and slackness of the fibres, nerves, muscles, &c.

RELAY, a supply of horses placed on the road, and appointed to be ready for a traveller to change, in order to make the greater expedition.

RELEVANCY, in Scots law. See **LAW**, Tit. xxxiii. 48.

RELICS, in the Romish church, the remains of the bodies of saints or martyrs, and the instruments by which they were put to death, devoutly preserved, in honour to their memory; kissed, revered, and carried in procession.

RELICT, in law, the same with widow.

RELIEVO, or **RELIEF**, in sculpture, &c. is the projection or standing out of a figure; which arises prominent from the ground or plan on which it is formed; whether that figure be cut with the chisel, moulded, or cast.

There are three kinds or degrees of relievo, viz: alto, basso, and demi relievo. The alto-relievo, called also haut-relief, or high relievo, is when the figure is formed after nature, and projects as much as the life. Basso-relievo, bas-relief, or low relievo, is when the work is raised but a little from the ground, as in medals, and the frontispieces of buildings; and particularly in the histories, festoons, foliage, and other ornaments of friezes. Demi-relievo is when one half of the figure rises from the plan.

When

When, in a basso-relievo, there are parts that stand clear out, detached from the rest, the work is called a demi-basbo.

RELIEVO, or RELIEF, in painting, is the degree of boldness with which the figures seem, at a due distance, to stand out from the ground of the painting.

RELIGION, or THEOLOGY.

I. TO know God, and to render him a reasonable service, are the two principal objects of religion. We know but little of the nature of bodies; we discover some of their properties, as motion, figure, colours, &c. but of their essence we are ignorant: we know still much less of the soul; but of the essence or nature of God, we know nothing: it is the prerogative of the Supreme Being alone to comprehend his own essence: all the efforts that we can make to attain that knowledge, are arrogant and ineffectual; it is foreign to the nature of a limited spirit: but our destiny is that of a man, and our desires are those of a God. In a word, man appears to be formed to adore, but not to comprehend, the Supreme Being.

II. We may say, however, with Virgil, *Jovis omnia plena*; God manifests his existence, not only to the internal sensations of our minds, but in every object that surrounds us in the whole frame of nature; and if we cannot comprehend the Supreme Being by our senses, we may discover his attributes by our reason, almost as clearly as we distinguish the properties of matter, and many other objects: and this knowledge is sufficient for us. The end of every other science is some temporal happiness; theology alone proposes an eternal felicity; its object therefore differs from all other sciences, as the age of threescore and ten differs from eternity. We cannot wonder therefore, that all the inhabitants of the earth, from the time of the creation, have made it their principal study, and have exerted all their abilities in the cultivation of it: we ought much rather to be astonished that it does not yet more strongly engage the attention of mankind; and that while they labour so assiduously to acquire those sciences, whose utility extends to so short a space of time, they should so frequently neglect that object which can secure their felicity in a future, certain, and eternal existence.

III. From the first knowledge that we have of the world, that is to say, for about five thousand years past, men have blindly searched after the idea of the true God; and by the weakness of their discernment, they have fallen into a thousand errors. Paganism at first covered the whole earth, except that family alone which became the stock of the Jewish people: this paganism among different nations had different mixtures of idolatry. Moses first made known to the Hebrews the true God, and prescribed them his worship: his religion, however, was not adopted by any other people, not even by their neighbours. Jesus Christ appeared upon the earth, abolished a part of the Judaic law, reformed the religion of Moses, taught his divine doctrines, and offered himself as a sacrifice for the salvation of mankind. His gospel made a happy progress over all Europe, that is, over the then known part of the earth. Some time after, Mahomet arose in the east and preached a religion that he had compounded of the Jewish and Christian, and of his own ideas. Lastly, came Luther and Calvin who reformed the errors which, according to them, had been introduced into Chri-

stianity under the reigns of the popes; and gave the idea of what is called the Protestant Religion. Confucius had taught the Chinese, and Zoroaster the Indians, religions drawn partly from philosophy, and partly from paganism; but the extent of these was very confined. All these religions, and their different sects, have had their theology, their priests, their ceremonies, their triumphs, and even their martyrs.

IV. We shall not speak here of religions that are extinct, or that yet exist, but at a distance far from us: we shall treat only of the Christian theology, which teaches us to know God, by revelation and by the light of reason, so far as it is possible for the weakness of the human mind to comprehend that inscrutable Being. The knowledge of the true God is indeed of little utility to man, unless he can suppose that there is some connection or relation between that Supreme Being and himself. Now it is from these connections or relations that are derived the necessity of the knowledge of the true God, and of the true manner in which he is to be worshipped: and this it is that forms the Christian theology; of which we shall now give the analysis.

V. To ascend by a chain of reasoning from things visible to things invisible, from palpable to impalpable, from terrestrial to celestial, from the creature even up to the Creator, is the business of theology: it is not surprising, therefore, that the union of many doctrines is necessary completely to form such a science. To understand, and properly to interpret the scriptures or revelation, demands not less sagacity than assiduity. The gift of persuasion is also essential to the ministers of the gospel. And lastly, the civil government has committed to their care certain functions of society, which relate, or seem to relate, either to the doctrines or morality of the gospel. They assemble, for example, in bodies to form consistories; they judge in matrimonial cases; they carry consolation and hope to the souls of the sick; they prepare for death those criminals which justice sacrifices to public safety; they take upon themselves the charge of *Ephors*, with the inspection of some pious foundations; they distribute alms; they administer the sacraments, &c.

VI. To discharge fully so many duties, the theologian has need, 1. Of several preparatory studies; 2. Of some theoretic sciences; and, 3. Of many doctrines which have for their object his ministerial office. The first are,

1. The languages; and among these,

- (a) His native language, in which he is to preach and exercise his ministry, and with which he ought to be perfectly acquainted.
- (b) The Latin language, which is the language of the learned world in general.
- (c) The Greek language, in order to understand the New Testament.
- (d) The Hebrew language, of which the Talmudian and Rabbinical idioms are a part.
- (e) The Arabic language.
- (f) The Syriac language.

(g) The

- (g) The French language. And
 (h) The English language. The two latter of which now appear necessary to every man of letters, and particularly to a theologian, on account of the excellent works which are wrote in those languages.

2. The principal parts of Philosophy; as,
 (a) Logic.
 (b) Metaphysics.
 (c) Moral philosophy.
 3. Rhetoric and eloquence, or the art of speaking correctly, of writing with elegance, and of persuasion.
 To which may be added,
 4. The elements of Chronology, and Universal History.
 5. The study of the Jewish antiquities.

He who would devote himself to the important employment of a theologian, and has the noble ambition to excel in it, should early impress on his mind these truths: that the years which are passed at a university are few; that they run rapidly away; that they are entirely engrossed by the theoretic sciences; and that he who does not carry with him to the university a fund of knowledge in the preparatory parts of learning, commonly brings very little away, when his age or his parents oblige him to quit it.

- VII. The theoretic sciences of a theologian are,
 1. The Dogmatic, or the theory of theology; which some Latin authors name also *thetica*, or *systematica*.
 2. The Exegesis, or the science of attaining the true sense of the holy scriptures.
 3. The Hermeneutic, or the art of interpreting and explaining the scriptures to others. This differs in general but little from the exegesis, and in some respects is quite the same.
 4. Polemic theology, or controversy.
 5. Natural theology.
 6. Moral theology.
 7. Sacred criticism.
 8. The history of the Church, under the Old and New Testaments.

- VIII. The practical sciences of a theologian are,
 1. Pastoral theology, which is divided into,
 (a) Homiletic.
 (b) Catechetical.
 (c) Casuistic.
 2. Confessorial theology, which comprehends
 (d) The Canon law.
 3. The prudential exercise of the different functions of the ministry.

We do not here particularly name the *patristic theology*, (*theologia patrum seu patristica*;) because all Christian communions are not agreed in their opinions concerning the degree of authenticity and infallibility that is to be attributed to these ancient fathers of the church. The Protestants believe, that these primitive theologians were liable to error in their sentiments as well as those of our days; and, in all probability, that they were less skillful, less learned, less clear, and less accustomed to close reasoning, than the latter, as philosophy was then more imperfect. But as we find in the writings of these fathers, many elucidations of the doctrine of the primitive apostles, and many irrefragable testimonies of the authenticity of divers remarkable events, which serve to establish the truth of Christianity; and as we there see, moreover, the origin of errors, of arbitrary ceremonies, and of many doc-

trines that have been introduced into the Christian church; the reading and the study of these fathers cannot but be of great utility to the theologian. To a virtuous citizen, who unites such various sciences, and employs them in pointing out to his fellow-citizens the path that leads to temporal and eternal felicity, in a word, to a wise theologian, what veneration is not due?

Of the DOGMATIC.

I. UNDER the general term of dogmatic, we comprehend that part which the different writers on theology have called sometimes theoretic, sometimes systematic, and sometimes *thetic theology*, &c. The term dogmatic appears to us the most general, and the most just, to express the subject that we intend, as it comprehends an *entire system of all the dogmas or tenets that each religion professes*; whether it teach these dogmas by the way of thesis, as articles of faith; by public lecture; by catechising; or any other manner whatever.

II. Every positive religion must, naturally, have a system of certain points of doctrine to propose to its followers; otherwise, each one would form a particular system according to his own fancy: there would be as many different religions as there are individuals on the earth, and each society would consist of a confused mass of fantastic opinions; as the different modes of thinking, and the different degrees of discernment, are varied and compounded by mankind to infinity; but truth, on the contrary, is uniform and invariable.

III. The Christian religion is as compound in its dogmas, as it is simple in its moral principle. It includes, 1. The dogmas founded on the lights of reason: 2. Those drawn from the Old Testament, and the law of Moses: 3. Those taken from the New Testament, and the doctrine of Jesus Christ: 4. Those that the fathers of the church have drawn from the Holy Scriptures: 5. Those that the church, under the New Testament, has prescribed to Christians, by œcumenical and other councils assembled in different ages: 6. The dogmas that the popes, in quality of heads of the church, have established by their bulls: and to these must be added, on the part of the protestants, 7. The dogmas that the reformers, especially Luther and Calvin, have taught: 8. The decisions of synods; and lastly, the tenets that are maintained by the different sects, as Socinians, Anabaptists, Quakers, &c. Each of these particular religions or sects pretend to support their dogmas both by reason and revelation: we do not here offer a work of controversy, and are very far from attempting to determine on which side truth and reason are to be found.

IV. Our zeal, however, for the Christian religion in general, which we regard as perfectly divine, and as the only religion adapted to promote the happiness of mankind in this world, and to secure it in the next, and the desire we have that it may endure to the end of time, compels us to make in this place one important reflection; which is, That simplicity is ever an essential attribute of perfection, as complexity is of imperfection. Now, it cannot be denied, without doing violence to truth, that among the different dogmas of which we have been speaking, there are several that seem to be founded on speculations very abstruse, on subtleties very intricate, and on interpretations very ambiguous. God certainly never intended that all mankind should be theologians; he has not given them his divine word to be the cause of discord among men, nor that they should pass their whole lives

lives in a painful search after *objects of belief*, and *articles of faith*; and that they should forego, in that pursuit, the necessary offices of life, and their duties as citizens. The dogmas, then, essentially necessary to the welfare of mankind, ought to consist of a small number, and to bear the marks of simplicity and perspicuity; without which they must be imperfect, and consequently the work of man. Our intention, in making this remark, is, to extend our voice, if it be possible, even to posterity, whom we would conjure not to injure our religion, so holy and so admirable, by a multiplicity of dogmas. It is necessary, however, that the divine, who makes it his study and his profession, should be thoroughly acquainted with the theory of this science, in order that he may be able to instruct the sincere Christian, and to explain the nature of each particular dogma, as well as the solidity of its proofs; and to this it is that the study of the dogmatic leads; of which we shall now continue the analysis.

V. The dogmatic is then nothing but a *succinct exposition of all the dogmas of the Christian religion, in a natural and philosophical order*. By the word philosophical, we do not here precisely mean the method of mathematicians, in the manner the late M. Wolf has applied it to philosophy; every subject is not capable of a demonstration so exact and rigid; but a regular order is required in the arrangement of the general system, and a connection is to be preserved in the several matters that form it: the definitions should be just; the divisions exact; the arguments solid; the proofs clear; the citations conclusive; the examples striking; and, in a word, every thing should be adduced that appertains to so important a discipline.

It is very essential, moreover, in the dogmatic, at the beginning of each thesis, to explain the several terms that are peculiar to it, and that use has established in treating of theology; to draw from each definition certain axioms and from thence to form propositions, and to illustrate them by solid reasoning. Lastly, we should not neglect, in such a system, to make use of the expressions used in the symbolic books that have been received by the whole Christian church, and which cannot be rejected or altered, without causing a confusion in our ideas, and in the general system of the Christian religion. But before we make the least advance in the study of Christian theology, it is indispensably necessary to examine the proofs by which the truth, the authenticity, and the divinity of the sacred and canonical books are established; for this is the foundation of all the dogmas and the axis on which its whole doctrine turns.

VI. The systematic part of the Christian religion, among the great number of its dogmas or theses, has *three principal*, from which all the rest are derived, and which form the basis of its whole doctrine:

1. The existence of one God in three persons.
2. The necessity of a Mediator or Redeemer.
3. The real appearance of the Mediator or Messiah on the earth.

Whoever writes, professes, or teaches the dogmatic, should be, above all things, careful well to establish these important truths: to evince them by the strongest and most evident proofs, drawn partly from the lights of reason, and partly from revelation: and he will then see, with what facility all other theses flow from, and how easy it will be to prove them by, these.

VII. The infinite variety that is found among mankind in their manner of thinking, and in their method of treating subjects; the frequent changes that have happened in the exterior form of philosophy, and in the method of treating it; the oppositions that have been raised at all times against divers doctrines of the Christian religion; all these have produced, among theologians, different systems of the dogmatic. Sometimes they have combined positive theology with morality, and have formed a system that they call *theologia theoretico-practica*, or *theologia thetico-moralis*, &c.: sometimes they have refuted the arguments that others oppose to certain theses; and from thence has arisen a system that they call *theologia thetico*, or *dogmatico*, or *positivo-polemica*: sometimes they have joined to natural theology that of revelation; and have formed a dogmatic, called *philosophico-theologica*: and so of the rest. But, besides that these distinctions and denominations are in themselves pedantic, it is at all times more eligible, in every science, to avoid confounding with each other the several branches of which it consists. The different dogmas, morality, philosophy, and controversy, are separate articles; and when each of these parts of theology are separately treated, they are disposed with more order in the mind, and a greater light is diffused over their several subjects.

VIII. It appears, moreover, from the simple enumeration that we have made, in the third section, of the different principles on which the dogmas of the Christian religion are founded, that, to be thoroughly acquainted with its whole theory, the theologian should also apply himself to the study of the symbolic books of its communion, and especially should be well versed in the *Creed of the Apostles*; that of *Nice* and *St Athanasius*; the book called *Formula concordiæ*; the *Theses of the council of Trent*; the *Catechisms of Luther*; the *Confession of Augsburg*; the *Articles of Smalcalden*; the *Catechism of Heidelberg*, &c. That he should be well acquainted with that part of Theology that is called *patristica*: that is to say, that he should be well read in the fathers of the church; that he should not be ignorant even of *scholastic theology*; that he should at least know the frivolous vanities and the complicated method of the ancient scholastic divines, which was derived from the philosophy of Aristotle and the schools; that he should make a serious study of the *sacred history* of all ages, the *councils and synods*; that he should, above all, never lose sight of *natural theology*; and, lastly, that it is indispensably necessary that he should procure a good bible-theque or treatise of ecclesiastical writers*, which he may consult occasionally, and learn from thence to know the best guides. The more a theologian applies himself to all these subjects, the more ability he will acquire in this science, and the more perfect he will be in the theory of that religion which it is his duty to teach to others.

IX. Revealed religion being founded (at least in great part) on natural religion, and philosophy being the source from whence the principles and the knowledge of the latter are derived, it is evident that philosophy is intimately connected with theology: nevertheless, the aid of the former is to be employed with precaution, and is not to be regarded as the foundation of the theological dogmas, but only as a mean by which they may be explained and enforced. The Holy Scriptures constitute, perpetually, the true basis of revealed theology: philosophy effectually concurs, however,

* Those of Du Pin and William Cave are most celebrated.

to prove the existence and the attributes of the Supreme Being; the necessity of the creation of the universe by Almighty God, in opposition to every other possible manner of its being produced: it furnishes, moreover, plausible conjectures concerning the intention of the Almighty in creating this world; it proves the necessity of a perpetual power to preserve it; it supposes, that, as God could not produce any thing that was not perfect in its kind, he could not have created man as he now is; it vindicates the conduct of the Supreme Being, in appointing chastisements for transgressions, by shewing that moral evil was not introduced into the world by absolute necessity, but by the abuse of liberty, the most noble prerogative of the human soul; it determines the necessity of a Mediator; it furnishes arguments for the belief of the immortality of the soul, and of a future state that has a relation to the moral actions of this life; and lastly, it inspires a love of God as a Being of sovereign perfection, a gratitude towards him as our creator and preserver, and a submission to his will as our supreme ruler and director, motives of all others the most powerfully conducive to a virtuous conduct.

X. It is this use which theology makes of philosophy, that has given occasion to divide the theses of the dogmatic into pure and mixed; that is, into theses that are founded entirely upon revelation; and, such as arise from an union of reason with revelation. Of the first sort are, 1. The article of the Holy Scripture itself; which treats of its divine origin, its authority, and its efficacy. 2. The dogma of the Trinity. 3. That of the origin of evil, or of original sin. 4. The whole article of Jesus Christ. 5. The dogma of the efficacy and operations of the Holy Ghost. 6. That of the sacraments. 7. That of repentance. 8. That of the belief in Jesus Christ. 9. That of good and bad angels. 10. That of the end of the world, and the last judgment. 11. That of the church, &c. The mixed dogmas or theses are, 1. The doctrine of a Supreme Being, in general; his being, his attributes, and his works. 2. That of the creation. 3. That of providence, or the conservation of the world. 4. Of sin, as a transgression of the laws of God. 5. Of rewards and punishments after death, &c. He that attentively studies, thoroughly comprehends, and well digests all these theses, will have reason to rest content with his knowledge of the dogmatic.

Of the EXEGESIS and the HERMENEUTIC.

I. The term *Exegesis* is derived from the Greek verb *EXE'GONSTAI*, which signifies to relate or explain; and that of *Hermeneutic* from *ERME'NEUEIN*, which means to search into, and, in a figurative sense, thoroughly to examine, and interpret. The learned, and especially the theologians, make use of these words, sometimes as synonyma, to express the same thing, and sometimes (as there are scarce any terms that are perfectly synonymous) to denote a small difference between two parts of learning of the same nature. By the word *Exegesis* they mean, *that science which teaches clearly to investigate the true sense of the original text of the holy scriptures*; and by the *Hermeneutic*, *the art of interpreting and explaining the holy scriptures to others* *. This distinction is so subtle, that it becomes almost frivolous. They are, in fact, the same science; the one is only an explication of the other, and for that reason

we think we are authorized to treat of them together in this place.

II. In order to the true understanding of the sacred text of all the books contained in the Holy Bible, whether of the Old or New Testament, it is absolutely necessary that the theologian be thoroughly acquainted, not only with the languages in which these books were originally wrote, but likewise with the history and antiquities of those remote times in which their authors lived. With regard to researches into the history of the Jewish nation, their antiquities, their morals, and their customs, it will be found advantageous to pursue it as far as the nature of the subject will admit, without, however, engaging in critical subtleties, that lead to a labyrinth to which there is no end, and have spread more clouds over theology than even the scholastic controversies have formerly done.

III. He who would successfully interpret any work whatever, should first consider the spirit in which it is wrote: he should attentively reflect on the general design of that work, and the particular motives that induced the author to undertake it; his genius, his passions, his taste; the time, the place, and the people for whom it was written. These considerations are, above all, necessary, when we would undertake the explication of the Holy Scriptures. Independent of those reflections which the theologian will of himself naturally make on the subject, the excellent commentaries which we have on the Bible, in which the greatest men of every age have exercised their genius, may serve him as a guide in this course. The critical histories will likewise afford great aid, and throw admirable lights on this matter. Clear ideas, an acute discernment, and a solid judgment, will complete the work.

IV. With regard to the languages necessary for understanding the sacred text, the Hebrew language hold the first place. The student should have early recourse to the *manner of accenting*, and the *Massora* of the Jews: to these he may add, with advantage, the reading of the Jewish interpreters or *Rabbins*. There are the grammars and dictionaries, Rabbinic and Talmudic, of Buxtorff, Cellarius, and others, which greatly facilitate his study. The Talmud, it is true, is stuffed with a thousand fables and ridiculous stories; it contains, notwithstanding, some things useful and curious, which the learned theologian should not entirely pass over. For the well understanding of the explications and applications of the best Rabbins, he should likewise have recourse to their *Cabbala*, which they divide into *real* and *liberal*.

V. The *Massora* is a kind of critic on the Hebrew text, that the ancient Jewish doctors invented, in order to prevent any alteration. They there count the verses, the words, and the letters of the text, and have marked all their diversities. The text of the sacred books was formerly wrote in close continuation, without any distinction of chapters, verses, or even words, after the manner of the ancients, as we still see in many manuscripts. As the sacred books have undergone an infinity of changes, which form various readings; and as the true original has been either lost or altered; the Jews have had recourse to this rule, which they have judged infallible, and which they call the *Massora*, to fix the reading of the Hebrew text.

VI. The ancient Rabbins, or Doctors of the Jewish law, have

* The *Exegesis* is a kind of rational grammar. The *Hermeneutic* is the art of interpreting entire passages.

have wrote many superstitious traditions, which they observe as scrupulously as the law of Moses; and have also made many commentaries on the sacred text, among which there are some that are good and useful. The language they use is different from the common Hebrew, as is also the Rabbinic character.

VII. The *Talmud* is a book in which the Jews have comprised every thing that concerns the explication of their law, and the duties that are enjoined by scripture, by tradition, or by authority of their doctors; by their particular customs, their civil government, their doctrine, their ceremonies, their moral theology, the decisions of cases of conscience, &c. The *Talmud* is composed, in general, of two parts; which are called, the *Mishna*, and the *Gemara*. The Jews would not at first commit these things to writing; but after the destruction of Jerusalem, finding themselves dispersed in the world, they became obliged to do it. They had two celebrated schools, one at Babilon, and the other at Jerusalem; at these schools were made two different collections of traditions, each of which is called the *Talmud*. The commentary, called *Gemara*, contains the decisions of the Jewish doctors, and their explications of the text; it is filled with absurdities, reveries, and ignorance, and written in a vulgar style. On the contrary, the text, that is called *Mishna*, consists of solid reasoning, written in a pure style. The Rabbins Moses, son of Maiemon, has made an abridgement of it, which is of more value than even the *Talmud* itself.

VIII. The Cabbala or Kabala (a Hebrew word, which properly signifies tradition) contains the different interpretations of the laws of God by different Rabbins; their decisions on the obligations that they impose, and the manner of performing them. There are some of them that are occult and mysterious, and consist in singular and mytic significations which are given to a word, or even to each of the letters that compose it; and from these various combinations, they draw explications of the Scripture very different from that which it seems naturally to import. This *Cabbala* is divided into three kinds: the first they call *Gematria*, and consists in taking the letters for the numbers of arithmetic, and explaining each word by the arithmetic value of the numbers that compose it: the second is called *Notaricon*, and consists in taking each letter for a word, or in composing a word of the first letters of several words: the third is called *Thémura*, and consists in changing a word, and the letters of which it is composed.

IX. The *Chaldee* seems to be indispensable, after the study of the Hebrew and Rabbinic; this is properly no more than a particular dialect of the Hebrew language. The Jews give to their commentaries, and to the Chaldaic paraphrase on the Scripture, the title of *Targum*. As, during their long captivity in Babylon, they had forgot the Hebrew, and only retained the Chaldaean language; it became necessary to explain the prophets in that language; and to this necessity is owing the first commencement of the Chaldaean paraphrase. The Rabbins have since collected together these divers interpretations of their doctors, which form the paraphrase that is called *Targum*.

X. The other oriental languages, as the Arabic, the Syriac, the Samaritan, and the Coptic, are also of great use to the learned theologian.

XI. All the books of the New Testament being wrote in Greek, the study of that language becomes necessary to the

theologian. But it must not be imagined, that this Greek is that of Athens or Lacedemon; and that they who understand the New Testament, will fully comprehend Homer, Anacreon, or Thucydides. It is very necessary to observe, here, that during the Babylonish captivity, the Jews, as we have just said, having forgot the Hebrew, and having adopted, in process of time, several idioms, the Greek language was at last successfully diffused over almost all the east; and, at the time of the coming of Jesus Christ upon the earth, that language was in use in Palestine, not only among men of letters, but in the polite world: every thing was wrote, every thing was treated of, in Greek. The Jews no longer understood the Holy Scriptures in the Hebrew language, but made use of the version that the Septuagint had made of the Old Testament in the Greek language. The evangelists and the apostles, therefore, wrote their historic relations, as well as their epistles or letters, in the same language: but their style is not pure, being strewn with hebraisms and barbarisms, and with theological terms and phrases. The four evangelists differ, moreover, among themselves, with regard to their style; and so do the apostles: St Matthew is not so elegant as St John; nor St Jude so elegant as St Paul, who was a man of letters, and an able writer. The diction of St Luke is the most elegant, and most correct, especially in his book of the acts of the apostles.

XII. The translations that have been made of the sacred books in the west, will also very frequently assist in clearing up many passages.

XIII. The Jewish antiquities are naturally connected with the study of the sacred history of the Old Testament. *Josephus* is the best author who has wrote on this subject. *John Marsham*, *Vossius*, *Lælius*, *Gyraldus*, &c. are the moderns to whom we are indebted for learned researches in these matters. *Hermannus Witsius*, in his treatise de *Ægyptiacis*, has thrown admirable lights on the Egyptian antiquities. The antiquities of the Chaldeans, Babylonians, Persians and Medes, has been excellently well explained by *Barnabas Brisson*, in his book de *regno & rege Persarum*; and by *Thomas Hyde*, in his treatise de *religione et sacris Persarum*. The writings of *Mearsius*, and the *Compendium Antiquitatum Græcarum* of *John Potter*, are very useful to give theologians an idea of what they will find necessary to know of the Grecian antiquities; and lastly, the abridgement of *Cantel* will make them sufficiently acquainted with the Latin antiquities.

XIV. *Spencer* has given an excellent work on the ceremonies of the Jewish religion, de *Legibus Hebræorum ritualibus*, &c. We have likewise works that fully treat of their temples, their sacrifices, their priests and Levites, their passover and purim, of their tithes, their vestments and sacred habits, and of their manners and customs; but it would be too prolix to mention all these in this place.

XV. The modern commentaries on the Holy Scriptures may also serve to instruct the young theologian; but he should use them with caution and moderation. All that glitters is not gold, as well in this instance as in others; and a man of learning should not often make use of other people's eyes.

XVI. The Bibles called *Polyglots* are also of great assistance in interpreting the sacred text. They are printed in several languages. The first is that of cardinal *Ximenes*, printed in the year 1555, and called the *Bible of Complute*; it contains the Hebrew text, the Chaldaean para-

phrase, the Greek version of the Septuagint, and the ancient Latin edition. The second is that which is called the *Royal Bible*, printed at Antwerp in 1572. The third, that of *le Jay*, printed at Paris in 1645. The fourth is the *English polyglot*, printed at London in 1657, of which Walton is the editor. There are still several more that have been printed since, but they are neither so complete nor so celebrated as the former.

XVII. The Bibles that are called *Biblia Glossata*, are also here of very great use. The sacred text is there every where accompanied with explanations and observations. There are of these in each of the three principal communions of the Christian Religion, and in most of the modern languages of Europe. Lastly, as the interpretation of the sacred text depends in a great measure on the lights and the proofs drawn by comparing together different passages of scripture, there are several Bibles where the editors have placed, on the side of each verse of the text, what they call the *Concordance*, that is, a citation of other parallel passages, which are found dispersed in the Old and New Testament. These Concordances are of daily and indispensable use to the divine, in composing his sermons, and in many parts of his ministry. See BIBLE.

XVIII. These parallelisms are yet different from that which theologians call the *real parallelism*; by which they mean, the relation that the typical or parabolic sense of a passage has with what the expressions literally imply, or seem to imply; the mystic sense with the real sense; the figures and the images that the sacred authors have employed, with the things or the objects that they intended to describe. The greatest theologians have taken infinite pains in determining these points, explaining them, and producing their proofs: in many places they have succeeded; and we cannot but admire their sagacity, their zeal, and their success: it must be acknowledged, however, that they have not yet cleared up all the obscurities; that there are many dark passages still remaining in the prophets, in the Song of Songs, in the book of Job, and above all in the Apocalypse; on which have been hitherto thrown mere glimmerings, which are very far from affording a sufficient light. The explications that have been attempted of these passages are frequently so unjust, so unnatural, and improbable, and at the same time so futile, that they rebel against common sense, and only give us occasion to deplore the imbecility of the human understanding.

XIX. The last labour of him who would become acquainted with the Hermeneutic, is in what is called *Leſſio Aſcroatica*; by means of which, each book of the Holy Scripture is examined from one end to the other, with relation to geography ancient and modern, genealogy, chronology, history, and antiquities; from whence a rational system is formed, according to the rules of sound logic. This work is attended with so many difficulties and distractions, that it is almost impossible to accomplish it, without the assistance of a guide, an able professor, and a complete academic course.

XX. Furnished with these ideas, the theologian may venture to investigate the true sense of those passages of Holy Scripture that may appear to him obscure, contradictory, or difficult, and to interpret them to others: but he will be more wise, and less vain, than to attempt to impose his decisions on mankind, at all times, as authentic and infallible. The human discernment is ever confined and imper-

fect; and God has not granted to any man, to any theologian; or assembly of divines, an exclusive power of interpreting his divine word: he has moreover denounced his anathema against all those who shall add, or take away, a single word thereof. But to explore the true sense of any passage, and to explain it to others, cannot certainly be deemed either adding or retrenching.

OF SACRED CRITICISM.

I. As the authors and professors, who treat of the different parts of theology, make frequent mention of the sacred criticism, we must not omit to shew in what manner it is connected with the Exegesis and the Hermeneutic, and in what respect it forms a separate doctrine or science. Criticism, in general, is in fact no more than a superior part of grammar; a kind of rational grammar founded on reflection, and the rules of language; but which employs the aid of divers other sciences, as history, chronology, antiquities, &c. in order to search out and determine the true sense of an obscure or ambiguous passage. The sacred criticism is only distinguished by its object; it adopts the same rules, but it adds others which take their rise and principles from the peculiar language of the New Testament; and has regard to the Bible in general, an account of the nature, essence, and qualities of its divine Author. So far it has an intimate connection with the Exegesis.

II. But, if we would consider it as a separate study, we may say, that it is a science which is employed in examining the exterior circumstances of the Holy Scripture. For example: in what time each book was wrote; who was its author; the precision and fidelity of the text; the distinction between the canonical books and the apocryphal; and many other matters of like nature. In order still the better to shew in what manner, and with how much precaution, the sacred criticism proceeds in its operations, we shall here recite some of those subjects that belong to its province.

III. It is commonly received, that it was Esdras who, after the return from the captivity of Babylon, collected and fixed the canon of the sacred books of the Old Testament. This at least is the opinion of the Jews, who all attribute to him that glorious work; and the assertion appears so much the more probable, as it was the same Esdras who reestablished their state, who brought the whole Jewish people into one body as a nation, and formed the Judaic republic, which was so intimately connected with their religion. The collecting of the canon of the books of the New Testament is attributed, with great appearance of probability, to St John; although historic and formal testimonies of it cannot be produced, unless it be what Eusebius relates of the four Evangelists. In process of time, each council has decided what books should thereafter be held by the Christian church as canonical; and we commonly find, at the end of the decrees of each council, a repertory or list of those books.

IV. The Old Testament was wrote in Hebrew, except a small number of passages where the dialect is Chaldean. The form of the letters or characters, as we now have them, are also properly Chaldean; whereas, before the Babylonish captivity, the Samaritan character was probably used. Buxtorff and Capell have had warm disputes upon the subject of the vowel-points: the former would retain these points, and the latter rejects them; each of them has had his adherents. As it is impossible to decide in this dispute but by historic proofs;

proofs; and as these are not to be had, either for one side or the other; it is best to leave the affair undecided: not totally rejecting the points, however; as they are of infinite use in the study of the Hebrew language. They who love to introduce novelties into religion, (say the partisans of Buxtorff,) would doubtless be charmed to see the points totally abolished, because they then could make whatever they pleased of the sacred text. The adherents of Capell maintain, on the contrary, that by the ignorance or inadvertence of copyists, these points may have been transposed formerly, or may be easily confounded and wrong placed hereafter; which may occasion the most dangerous errors; may give rise to contrary meanings, and whimsical explanations of the Scripture; whereas, by not admitting the points, an able theologian will preserve, at least, the liberty of explaining a passage according to analogy, and the rules of good sense.

V. The accents have given rise to full as many disputes. But this question is not decidable but by the same method as the preceding: for we clearly see, by all the ancient manuscripts, that even the Greeks and Romans have wrote without accents, but that both one and the other make use of vowels. In poetical works especially, it is almost impossible to omit them; and that language being now dead, without accents we can find no cadence, no measure. Father Montfaucon asserts, with great appearance of probability, that accentuation was not introduced till the seventh century.

VI. The language of the New Testament is the Greek; for all that is said of the gospel of St Matthew being wrote in Hebrew, and of that of St Mark being originally composed in Latin, is but weakly supported. The style, as we have already remarked, is not pure, whatever some zealots may improperly, and without reason, assert to the contrary. The language of the New Testament abounds with hebraisms.

VII. The precision, the truth, and correction of the text, is the result of repeated and judicious comparisons of the variations; of which there are, according to Dr Mill, more than twenty thousand. These variations have proceeded, partly from the negligence of the copyists, and partly from the ignorance of the revisors and correctors of the ancient manuscripts, who have frequently added and inclosed the comments, which were wrote in the margin, with the text. The heretics of the first ages, and the impostors, have also made divers alterations in the text itself, in order to support their errors; and these alterations have slid into other copies. It is the common rule to follow the most ancient manuscripts; as it is supposed, with reason, that they are the most correct: and to these are also added the most ancient versions.

VIII. The first of these versions is that of the *Septuagint*, which has been at all times highly esteemed, as well by the Jews as the Christians. The Hebrew language being lost by the Jews during the captivity in Babylon, and the Greek dialect becoming the common language of the east, that version was made in Egypt by public authority, and for the use of the common people. The second is that called the *Vulgate*, which was formed from the translation of St Jerome, and from another that was called *Verbo antiqua*. After these two translations come the Greek versions, among which are reckoned, 1. That of *Aquila*, who has translated the original Hebrew *verbatim*, by putting over each word of the Hebrew text, its corresponding Greek term. 2.

That of *Symmachus*, who applied himself to write the Greek with purity and elegance. 3. That of *Theodotion*, who has very closely followed the text, notwithstanding the fine language he employs. *Origen* published these versions in six languages in his edition of the Old Testament, which he calls *Hexapla*. To all these versions may be added, 4. Those of *Jericho* and *Nicopolis*, which are much celebrated. We have not now any one of these versions entire. The fragments that remain of them have been collected and published by *Drusus* and *F. Montfaucon*. Lastly, The *Syriac versions*, of which one was made on the Hebrew text, and the other on the Greek.

IX. The sacred criticism is likewise employed in acquiring a knowledge of the principal and most celebrated manuscripts, as well of the sacred text itself, as of the translations; in learning to discern the hand-writing, and the essential characteristics which distinguish the real original from the counterfeits: and lastly, it is employed in knowing the best modern editions of the Holy Bible; as for example, the Polyglots, among which those of London, of the years 1653 and 1655, are the best. The introduction by Walton, which is at the beginning of these editions, is a model and a masterpiece of sacred criticism.

OF MORAL THEOLOGY.

I. If it were allowable to compare the Saviour of the world to a weak mortal, we would say, that the conduct of Jesus Christ resembled that of Socrates, who has left us no part of his doctrine in writing, but whose whole instructions (as well as the particulars of his life) have been collected, digested, and published, by his disciples. The Evangelists are the only historians of the Messiah: it is to their labours that we owe the knowledge of his actions upon earth, and his divine doctrine. The four Evangelists, and the Acts of the Apostles wrote by St. Luke, contain therefore *alone* the history of the life of Jesus Christ, and the doctrine that he taught. His apostles and disciples began by paraphrasing his doctrine, as well by their evangelic sermons, as in the epistles they addressed to the faithful of several Christian Churches: they have given explanations, and have added pastoral instructions, which are in effect admirable; but which, nevertheless, form not the original text of the discourses of our Saviour. The bishops of the apostolic century, the fathers of the church in all succeeding centuries, the other bishops and ecclesiastics, the councils, the synods, the doctors of theology, the popes, the consistories, the reformers likewise, and an infinity of theologians, have drawn from the Gospel, and sometimes also from the letters of the apostles, and from other commentaries on the Gospel, various tenets; which, united, form at this day the general system of the Christian Religion. The theologians who devote themselves to the service of the altar, study this system in the dogmatic: the laity learn it by means of catechisms; and after they have made confession of their faith, solemnly adopt it, when they are received into the bosom of the church.

II. It is not the same with regard to the morality of Jesus Christ, which every one may read in the Gospel; and to know which, it is not necessary to become learned, nor to study a complicated system. If the dogmatic were not armed with a thousand arguments to establish the Divinity of Jesus Christ, yet would the morality of his Gospel sufficiently prove it; seeing that it is perfectly holy, entirely

simple, strictly just, and most completely adapted to promote the felicity of the human race in this world, and in that which is to come. The Saviour of the world has not enjoined any part of mankind to engage in disputes or abstract refinements: the sole command that he has given them is, *to believe in his Gospel*; and that is comprised in one word only, Love: the grand and only principle on which the whole of his sacred doctrine is founded.

III. To produce the greatest effects possible, by the least efforts, is the highest perfection in nature, and at the same time the true characteristic of Divinity. God has given to all the beings that compose the universe, one simple principle alone, by which the whole, and every part, is connected and perpetually supported; and that is Love. The attraction of the celestial bodies, as well as of those of which our globe is formed, is a species of *love*; a mutual tendency toward each other. The uniform generation, by which all beings are perpetuated, is founded in *love*. This is the true *minimum*, the true system of the *least action*, which includes something so divine. It appears to be the will of God to establish, by the mouth of the Messiah, the same simple principle in morality, that is, in the rule of human actions, by saying, *Love*: in a word, it was his will, that in the conduct of mankind, as in every other part of nature, there should be no other principle than that of Love.

IV. That in the different systems of ethics of the ancient Heathen Philosophers many maxims and precepts of admirable morality are to be found, cannot be denied; but, beside that these philosophers are almost continually contradicting each other in their maxims, no one of their systems is founded on the true principle. In searching after it, they have discovered some excellent truths; but it has been by chance, and they are at best imperfect. Jesus Christ has alone taught mankind perfect morals, by deducing them from this true principle. Every principle should be simple: the idea of a compound principle implies at once an imperfection. Every principle should be comprehensive, even universal in its effects. Every principle, whose effects are limited, is imperfect. God himself is uniform in his principle, and infinite in his effects. His doctrine, or his law, should be the same. Jesus Christ has made known to mankind this principle, simple and universal. He has therefore been, in this sense also, the true Saviour of the world. He has preached to mankind; and his only doctrine has been that of love.

V. By the word Love, with regard to *Bodies* in general, is meant a tendency, a mutual inclination that urges them to join and to coalesce; and with regard to men in particular, a lively, affecting pleasure, that possesses the mind on contemplating the perfections of any object. This pleasure is always accompanied with a desire, either to possess that object, or to render it propitious. By adopting therefore this principle, and this last definition of *Love*, it follows, that all the duties of man consist,

1. In the love of God in preference to all other objects.
2. In the love of himself.
3. In the love of his own species.
4. In the love of every other creature to a certain degree.

The doctrines of Jesus Christ are, in these respects, the most explicit.

VI. From this principle flows our *duty* towards God, towards ourselves, our neighbour, and to those beings that are subject to our power. The first rule is, to communicate to all those, whom it is our duty to love, all the good, and to

preserve them from all the evil in our power. The second, to do to no one what we would not have done to ourselves in similar circumstances. The third, which is the simple effect of love, is to endeavour to please the object that we ought to love. The fourth, to endeavour to render the pleasures that we communicate to others, as lively as possible and those inevitable evils, which we are sometimes constrained to do to them, as supportable as we can; and so of the rest. The whole evangelic doctrine of our Saviour is replete, from beginning to end, with admirable precepts for these purposes; and these precepts, with their applications, general and particular, we learn from that science which we call Moral Theology.

VII. This doctrine we distinguish from moral philosophy, or the simple doctrine of Ethics; because Jesus Christ has made known, in his divine morality, a far greater degree of perfection than is discoverable by the mere light of human reason. For the renouncing of self-interest, and private pleasure; the forgiveness of offences; the love of his enemies; the triumph over destructive passions; and many other like virtues, the Christian is alone indebted to the doctrine of Jesus Christ.

VIII. In order, to shew, moreover, in a few words, of how easy, just, and natural an application all these precepts are susceptible, we shall here give a few instances. "It is our duty to love God." Now nothing is more natural than to feel a lively and penetrating pleasure in the contemplation of the united perfections of the Supreme Being; nothing more natural than a desire to please him, and to render him propitious to us: and as it is not possible for us, weak creatures, to do him either good or evil, all our power to please him consists in offering him an upright heart; a rational devotion; to be possessed with gratitude toward him, and to exert all possible efforts to accomplish the end of our creation. "It is our duty to love all mankind;" and yet we inflict pains and chastisements on some of them: we even put them to death: but we chastise them only to render them better, to prevent them from becoming pernicious to society in general: we retrench the number of the living, as we cut off a corrupted branch of a tree, in whose preservation we are interested: it is because we love mankind, that we endeavour to prevent the destruction of the good by the malignity of the wicked: but it must ever be an indispensable necessity alone that can compel us to chastisement. "It is our duty, likewise, to feel a kind of love for other creatures, even for mere animals." Nevertheless we harrass, we oppose, we destroy them. If we harrass them wantonly, to support a criminal luxury, or to satisfy a brutal pleasure; if we pursue a savage chase, or encourage combats between animals themselves, or other like horrible diversions, we act contrary both to the spirit and the letter of the Gospel. But if we destroy a part of these animals, to serve as an indispensable nourishment to man, observing at the same time to put them to the least misery possible, and taking all necessary care for the preservation of the species, we act in conformity to the laws of nature and of morality; we employ to our own preservation, and to that of the rest of mankind, what appears destined to that purpose by the Creator.

IX. Moral theology likewise differs from philosophy, inasmuch as it requires that our virtues be absolutely disinterested: it enjoins us to fly the evil, and to pursue the good, merely as our duty towards God: it admits indeed the precept of the love of ourselves, and the love of our neighbour; but

but it regards this love only as a duty that results from our love towards God; and that from the principle, That God must love all his creatures as the work of his hands; and that we cannot therefore, from the very nature of love, please him, without entertaining sentiments of affection towards those to whom the Sovereign Lord of the Universe vouchsafes his benign regard. Now, as the Christian morality does not regard virtue, but as it is a duty towards God; and as it considers all our actions, that have any other motive, either as blamable, or at least imperfect, and as but little acceptable to the Supreme Being; it does not regard the advantages that result from them to society, but as useful consequences of the true Christian virtue; and from this principle it draws new arguments for the encouraging of mankind to the practice of it.

X. From what has been said, a second difference arises between Christianity and philosophy. The first adds to the second still new motives to the practice of virtue. That of redemption, and pardon, obtained by Jesus Christ, is not one of the least. Its argument is this: If God has so loved mankind, as to afford them the means by which the evil, caused by their own fault, may be abolished, it would be the greatest of all ingratitude and malice towards himself, if man should not endeavour to acknowledge this love, to merit it, and to embrace the means of pleasing God. A third motive, taken also from the merit of Jesus Christ, here offers itself as an auxiliary to the two former: According to the Christian doctrine, man has not by nature the power to practise all those virtues which are agreeable to God: but the same doctrine teaches, on the other hand, the conditions by which it is possible to please that most holy and perfect Being; and gives the Christian hope also, that he shall never labour in vain.

XI. Lastly, the Christian morality is of far greater efficacy in adversity, than philosophy: it carries with it a wonderful consolation in misfortune, and even in the hour of death; for the Christian may say, with the Apostle, *that godliness (or the practice of evangetic morals) is in all things profitable, having the promise of the present life, and that which is to come.*

OF POLEMIC THEOLOGY, OR CONTROVERSY.

I. We cannot sufficiently lament, that the church of the God of peace should be a *church militant*; and that a doctrine so simple and clear as that of the Gospel should be the cause of discord, even among Christians themselves. Nevertheless, as the truth is so difficult to discover in all things, and especially in matters of religion; as it is so frequently covered with the clouds of interest and ambition; as the same object appears so different to different men; and as error, in the face of the world, constantly assumes the mask of truth; it is but just that the true religion be furnished with arms to combat error, and to pluck off that deceitful mask by which so many poor mortals are seduced.

II. The theologian, who has made the proper preparatory studies, who is thoroughly instructed in natural religion, in the dogmatic and the hermeneutic, and who joins to these sound logic, is already well prepared for this spiritual combat: he is armed, but he is still to learn how to use these arms: he must also be made acquainted with the enemies he is to encounter, to know their force, and the arts they will use against him. It is plain enough, we suppose, that we here speak of spiritual arms; of those with which we are

furnished by reason and the Holy Scripture: evil be to him that employs any other: force is ever an infallible proof of the want of argument. The propagation of a religion by the sword, after the manner of Mahomet; persecutions, either secret or open; constraint, violence, every sort of religious war, is so atrocious, so contrary to the spirit of the Gospel, in a word, so detestable, that every true Christian must avert his sight from such infamous horrors.

III. Controversy is conducted, either from the pulpit or chair, by way of harrangue, by conversation, or by writing. The first quality that is necessary to a disputant is *reason*, and the next *moderation*; in what manner soever the contest is conducted, these two qualities should constantly be manifest, during the whole course of altercation.

IV. There are some errors that attack the *system* of religion, and there are others that attack even its *morality*. In order properly to oppose an error, we must begin by finding out its real meaning; we must therefore study the different systems of other religions, and the principal heresies, if we would successfully refute them. We don't mean by this, that the theologian should know all the errors that spring up in the brain of each individual; we speak only of those that are professed by whole sects.

V. They who attack our religion, found their opinions, either on the interpretation of the sacred text, or on philosophy, or history; and we should always oppose them with the same arms with which they pretend to defeat us. It is necessary to begin by divesting ourselves of all prejudice, in order the better to shew others those prejudices by which they are deluded. We should never make use, but especially when we oppose weak minds, of opprobrious terms in the course of the debate, nor contend about words or expressions, nor attack incidental circumstances that may attend erroneous principles; but bend our whole force against the root of the tree, the principal error; to uncover it, to dig it up, to destroy it.

VI. Polemic theology is taught in universities by two methods, according to the views of the student. If he learn it merely in order hereafter to defend his parishioners against the most prevalent errors, he is only to examine the principal controversies according to the systematic order of theology; and may content himself with knowing their true meaning, together with the arguments of those that oppose them. But if it be his intention to teach this science to others, or to engage in controversy, either by conversation or writing; in short, if he aspire to renown in it, he should study the origin and history of each controversy, he should make himself a complete master of the arguments for and against it, the exceptions that it makes, its interests, its different revolutions and actual state, &c. These follow, in this study, either the order established in the dogmatic, or that which is used in symbolic books, that is, such as treat on articles of faith.

VII. In order the better to elucidate the method to be observed in this sort of study, we shall say, that to acquire a complete knowledge of theological disputes, the student should, 1. Make the examen of each religion, and even of each controversy. 2. He should thoroughly examine his system in the symbolic books, and likewise the sources of his religion. 3. He should precisely determine the principal and capital error of each religion, sect, or individual; that which is the source from whence all the other errors flow. 4. Search into the political causes of each error, and each

each controversy, from history. 5. Examine the natural order according to which all the errors have taken their rise, the one from the other : and lastly, 6. Confront the respective arguments, the answers, and exceptions, that each party has made to defend its cause. To all this is to be added, 7. What they call *Collegium disputatorium*; an exercise, by which all that is learned in the closet and in the schools is called forth and animated, under the inspection of a professor; and the mind is accustomed to think, and the tongue to speak, with facility and efficacy.

VIII. The principal contests in which the theologian may be engaged, are, 1. Against those who admit of no revealed religion; as the atheist and deist. 2. Against those who admit of a revealed religion, but adopt not the true Revelation; as the Heathens, the Mahometans, &c. 3. Against those who believe only a part of the true Revelation; as the Jews. 4. Against those who add to the true Revelation matter foreign to it; as traditions, &c. 5. Against those who make a false interpretation of the sacred text, and draw from it erroneous systems; as the heretics and the schismatics, &c. And lastly, 6. Against those who make a wrong use of certain expressions of Revelation, and build, on whimsical notions, ridiculous systems; as the Fanatics, Quakers, &c.

IX. According to this division, the theologian will have to combat principally with,

1. The Atheists, with Spinoza at their head.
2. The Deists.
3. The Heathens and Idolaters.
4. The Mahometans.
5. The modern Jews.
6. The Arians and Manicheans, or rather those who in these days follow their ancient errors.
7. The Socinians.
8. The Catholics, opposed to the Protestants.
9. The Protestants, opposed to the Catholics.
10. The Molinists, opposed to the Janfenists.
11. The Janfenists, opposed to the Molinists.
12. The Reformed, opposed to the Lutherans.
13. The Lutherans, opposed to the Reformed.
14. The Arminians.
15. The Anabaptists.
16. The Weigelians.
17. The Quakers or Tremblers.
18. The Fanatics, at the head of whom is Jacob Bohm.
19. The pretended new Prophets.
20. The Indifferents.
21. The Pietists.
22. The Moravian Brethren, or the Herenhutens, &c.

X. Now, as each of the religions, communions, or heresies above mentioned, have not scrupled to publish to the world their dogmas and creeds, the theologian ought carefully to instruct himself in those symbolic books, in which each of them have comprised its system; to study and to make a good analysis of them; and to prepare such arguments as are the most just, the most weighty, and proper to confute them.

XI. Before we quit this subject, there is one remark to be made, or rather one caution that is very essential, which we would offer to the young theologian; which is, that the polemic is useful, and even necessary in the study of theo-

logy in general; but that it is a discipline which ought to be treated with great prudence and moderation. Disputation in general is a dangerous art; and religious disputation is a deceitful art, and of infinite peril. The student will do right well to remember, that there is no sect, no communion on earth, that is perfectly true in all its dogmas without exception; that there are some small errors in all religions; that infallibility never was, nor ever will be, the portion of humanity. He should likewise remember, that the masters who teach him, or the books that he reads, are constantly partial to the religion they profess; and that when he has supported a thesis, and confuted his adversaries in a collegial dispute (where his adversaries, as well as his preceptors, are of the same side of the question, and will not fail to adjudge him the victory,) he should be persuaded, that the victory would not have been so easily obtained had he contended with able adversaries of the opposite religion: he should remember, that we triumph without glory when we combat without danger; and let him not be vain of his laurels, nor imagine himself some wonderful scholar; seeing that it is very possible, that he may go off victorious from such a dispute, that he may receive vast applause from his professors and his colleagues, and at the same time have reasoned like a dolt.

XII. On the other hand, the most able theologians, and the most consummate professors in this science, ought to be constantly on their guard against the abuse of polemic theology; which frequently serves less to clear and confirm the truth of the dogmas of a communion, than to establish perpetual discord and hatred among Christians. Every theologian should also remember, that by the nature of the subject, it is not possible to produce *demonstration* in support of his theses and opinions; but that his arguments will be only valid, and preponderate in proportion to their degree of evidence; and lastly, that it is a ridiculous and insufferable vanity to imagine, that every man, who does not think precisely as we do, is guilty of palpable error.

PASTORAL THEOLOGY.

I. HAVING described the theoretic sciences of theology, we now come to those which regard the practice. It would be to bury the talents that God has given him, and the studies that he has made, if the theologian did not employ them to the edification of his neighbour, and the prosperity of the Church. His office in society is attended with constant and anxious labours. He is charged with the *cure of souls*, with the instruction of youth, with preaching of the Gospel, the conduct of his flock, and the administration of the Sacraments, with visitations to the sick and the dying, with calming the terrors of weak minds, with administering comforts to afflicted souls, and many other functions equally difficult and important. The practical sciences that we shall here describe, will serve him as guides in this unbounded field.

II. Pastoral theology is usually divided into three parts; which are,

1. Homiletic Theology.
2. Catechetic Theology.
3. Casuistic Theology.

To which are added,

4. The Consistorial Prudence.
5. The prudential Exercise of the different functions of the ministry.

As the homily makes a part of eloquence, it is unnecessary to say any thing of it in this place, but treat the others in their order.

III. It is in vain that a son of the church possesses all the sciences that belong to his profession, that he is an agreeable and even a renowned preacher, if he do not give a life, an efficacious spirit, to his ministry, by a *good example*; for that is the first precept in pastoral theology. He is at the head of a flock, and ought to be their guide; but how absurd, if his words and his actions be at continual variance with each other! How scandalous, if he be not the first to practise these lessons of wisdom that he preaches! How indecent, if, while he edifies by his discourses, he disgusts by his morals! What baseness, if he should even glory in his irregularities! It is less shameful for a soldier to relate that he has tamely suffered an affront, than for an ecclesiastic to boast of his debaucheries! Both the one and the other is a disgrace to his profession.

IV. But this exemplary conduct should be free from all affectation in the external behaviour. A singularity of dress, and an air of austerity; the head declined, the eyes turned up to heaven, the hands constantly clasped, a plaintive tone of voice, and a solemn gait; a scrupulosity in things indifferent, and a dogmatic and clerical manner of deciding in the common affairs of life; a ridiculous inclination to discover iniquity in innocent actions; to confound pleasure with vice, and to be an enemy to joy, the greatest boon that God has bestowed on man; and a hundred other like fopperies there are, with which the religious make a parade, that is shocking both to good sense and the evangelic morality, and which render their ministry, in the eyes of sensible people, more contemptible than respectable. There are rocks on which the young theologian is much too liable to run, and of which he cannot be sufficiently cautioned.

V. After this candid caution, and brief introduction, we pass to the examen of the different parts, the union of which composes the system of the pastoral, the most important article perhaps, in all theology. The design of Revelation was, without doubt, to conduct man by faith to a virtuous life. It is not the opinions or the learning of weak mortals that can determine their intrinsic merit; it is their wisdom, their regularity of conduct, that must stamp their value. Experience shews, that a man of great genius and learning may be also a great villain; one who is unable to please God, or his neighbour: the virtuous Christian, on the contrary, must be agreeable to both; it follows therefore, that the practical part of theology, which leads mankind to a virtuous conduct, is of all its parts the most important.

CATECHETIC THEOLOGY.

I. By Catechetic Theology is meant, *The art of teaching youth, and ignorant persons, the principal points of the Evangelical Doctrine, as well with regard to belief as practice.* This application of the theoretic sciences of theology ought to be conducted in the most simple manner possible. It is not every one who is possessed of the talent of properly composing and delivering catechetic instructions; and it is an art that is very necessary in the Christian church.

II. The greatest difficulty consists in separating the articles of faith that are absolutely essential and indispensable to the salvation of mankind, from those that are subtle and speculative, more liable to contradiction, and less necessary

to such as do not make theology their profession. However, as children do not always remain children, and as the church is composed of persons of both sexes, and of all ages, it is necessary, that, in the explanations of the catechism, there should be employed different degrees of simplicity, proportioned to the age and capacity of those that are to be instructed. It is expedient for young people to retain in their minds the first principles of religion, such as are contained in good catechisms; and that they be explained to them in particular lectures; which is the most usual and most natural method of enabling youth to give an account of their faith. The sermons that are given in the catholic churches on controversy, and in protestant churches on the catechism, serve to instruct those who are of riper years and have their judgment more formed. These sermons compose, at the same time, a sort of course of the dogmatic and the polemic theology.

III. Both in private catechising, and in sermons that are purposely intended to explain the catechism, the theologian should avoid, as much as possible, the use of technical terms; or (which is still better) he ought to begin by explaining those terms, of which he should give such clear and determinate definitions, that no person of a moderate capacity can possibly mistake them. In a word, he should endeavour more to prove than to persuade; and as eloquence sometimes persuades at the expence of truth, he should cautiously avoid that sort of delusive persuasion, and in its room substitute clear and solid argument.

IV. The catechumen should not only be instructed in the tenets of his own religion, and the foundations on which they are built, but also in the dogmas of other religions, and the proofs that are brought to maintain them: for a subtle, deceitful and specious book may fall into his hands, or he may be drawn into a dispute with an able adversary. It is necessary, therefore, that he be provided with arms offensive and defensive, that he may be able successfully to defend himself; and, if it may be, to convert his antagonist, and by that mean promote the glory of truth and of religion. It is the part, therefore, of his preceptor, to teach him faithfully the principal tenets of other religions, and the arguments that are brought to defend them.

Of CASUISTIC THEOLOGY.

I. HAPPILY for man, and for society, all are not so obstinate, or so insensible, as to ask, *what sort of animal conscience is*, or never to know what is remorse. Happily, the greatest part of mankind are sensible, that all their actions are not conformable to the laws of divine wisdom, nor to the rules of natural equity; are afflicted at their past conduct, and find a generous and earnest desire arise in their souls to avoid for the future those dangerous rocks. To calm the troubled mind; to appease the timorous conscience; to communicate the consolations of grace to the afflicted soul; to explain and decide in doubtful cases; to direct those that err, and to support their weakness; to convince such as persist in their errors; to pierce the hardened heart; to intimidate the wicked, and to rouse the indolent; to conduct the Christians, committed to the care of their pastor, in the way that leads to true felicity; are the important objects of casuistic theology, and for which it affords the proper instructions.

II. In a more confined sense, by casuistic theology is meant, the science that decides in doubtful cases of moral

theology, and that calms the scruples of conscience which arise in the Christian's soul during his sojourn in this world.

III. The studies relative to these objects, which the theologian is supposed to have made, and the confidence that the common rank of Christians place in their pastors, afford them the means and the opportunities of rendering signal service to those of their fellow citizens who have need of their counsel and consolation: for where there is one man of a philosophic spirit, one Christian of a well-grounded knowledge in theology, there are in a society a thousand that are not, and who are yet desirous of being instructed, guided, comforted, established. It is therefore both just and important, that he who devotes himself to the service of the altar, should early study all those sciences that will enable him worthily to perform this important part of his ministry.

IV. God forbid, however, that we should countenance the abuse that is made, in some Christian countries, of the duties that we have here explained. To reduce these matters into a political system; to make the direction of consciences a profession, a regular trade; to provide each house with a spiritual director, as with a butcher or baker, a steward or porter, who by that mean may insinuate himself into the confidence of families, and become the depository of all their secrets; may sometimes sow discord between husband and wife, or the nearest relations; who may avail himself of the confidence of his devotees, to direct them constantly in matters of a worldly, and sometimes even of a criminal nature; to efface the legitimate and sacred authority of the father of a family, and, in its place, to substitute a foreign power; to undermine the confidence, the union and concord of families, in order to confirm and render necessary this secondary authority; to captivate the spirit, and oft-times the heart of a wife or daughter, and in general of weak minds; to enjoin them ridiculous nummeries that lead to fanaticism, and a thousand dangerous superstitions, or to religious exercises that divert them from their domestic duties; in a word, to assume an absolute authority over the consciences of mankind, is a pernicious invention, contrary to the evangelical moral, to the welfare of society, to the interest of the state, and to the sovereign authority; and well deserves an exemplary punishment.

V. But the cure of souls, faithfully intended, and properly limited, differs totally from this despotic power. He, who is charged with it by a lawful vocation, should remember that there are four classes of men with whom he will be engaged: 1. With those of weak minds; of little knowledge, and little ability. 2. With those whose spirits are afflicted by some great reverse of fortune. 3. With those of nice and timorous consciences, who suffer by their scruples, whether they be vain or rational. 4. And lastly, the wicked, the hardened and incorrigible sinner. The grand art here consists in representing to each of these classes of men, the truth, in a manner so clear, so strong and full, that they can no longer retain any doubts, that conviction must take place, and consolation or conversion be the consequence.

VI. Truth is in its nature highly problematic: each one, however, is persuaded that he knows it, that he possesses it, and is guided by it; every man thinks himself in the right. We should therefore begin by discovering the truth in the subject before us, and in placing it upon a solid foundation. This business of demonstrating the truth to others, is attended in the mean time with infinite diffi-

culty. Every mind is not capable of discovering it at the first glance; nor can all discern it from the same point of view. Sometimes men require conviction by abstract or philosophical arguments, and sometimes by the express decisions of the Holy Scripture. Sometimes by authority, sometimes by gentle remonstrance, and sometimes by dreadful menaces. Sometimes they are to be reclaimed by properly exposing the necessary and fatal consequences that result from their conduct; and at others, by the alluring promises of the Gospel. Now vice is to be boldly confronted; and now the transgressor is to be conducted into the right path by artful turnings: now the sinner's crimes are to be painted in the strongest colours; and now a veil is to be lightly cast over them; and sometimes we should even indulge a favourite inclination, in order to induce them to abandon a more pernicious passion: and so of the rest.

VII. As it is impossible that the books which have been wrote on this subject, though of an immense quantity, can contain every case that daily occurs in the ministry of the Gospel; and as these cases are not always justly decided by these authors; and, if they were, the consulting of such enormous works would take up too much of a theologian's time, and divert him from his other studies; and as these casuistic writers contain, moreover, a number of puerile subtilties, and wretched chimeras; it is highly proper that the minister of the altar, whom we suppose to have a masterly knowledge of the principles, the dogmas, and moral of the Christian religion, should endeavour to draw from the true source the means that he is to employ on each occurrence, and not have recourse to books for their decisions. For which purpose it is necessary, 1. That he accustom himself to reason according to the rules of sound logic. 2. That he learn to know the human heart, under its different disguises; the characters of men, their arts, and ruling passions. 3. That he do not attempt to gain or convince by little pious frauds, or by lucky sophisms artfully represented. 4. That he do not insist what are called penances, which are the height of absurdity. 5. That he do not enjoin nummeries, pilgrimages, austerities, and a thousand like matters, which can never carry with them a real conviction, and only serve to divert men from their labours and the duties of society. But, 6. That he constantly present, as we have before said, and cannot too often repeat, the truth, in all its native force and purity.

VIII. This truth, however, is no enemy to sacred eloquence; on the contrary, the latter serves to introduce the former into the mind of the auditor, and there to give it such strong impressions, as neither time, the dissipation of the world, nor the distractions of fortune, are able easily to efface. The whole ministerial function consists in teaching, preaching, administering the sacraments of the church, visiting the sick and the dying, comforting the afflicted, and affording the spiritual aids to all those who have need of them. Eloquence is of the greatest efficacy in all these functions; and, without affecting it, the minister of the gospel should never neglect it. There are some professors in universities who give their auditors a complete systematic course on pastoral theology, which may be attended with many advantages.

CONSISTORIAL PRUDENCE, or GENERAL OECONOMY of the Church.

I. AMONG the practical sciences of theology, we must
not

not pass over in silence that which is called the Consistorial or Ecclesiastical Prudence; whose object is the exterior order or arrangement of the Christian church, on principles founded on the Holy Scriptures; and which are proper, not only to maintain religion in its purity and splendor, but to defend it against all schisms, dissensions and separations whatever. This economy is necessary in the councils, the synods, the consistories, and in the faculties of theology. We must not, however, confound this with the ecclesiastical jurisprudence, which is the science of interpreting and applying the laws, instituted by the sovereign, relative to the persons, goods, and affairs of the church; whereas the object of consistorial prudence is the arrangement of the church itself, and the ecclesiastical state, on Christian and rational maxims. The one is a sort of legislation in itself; and the other, on the contrary, an application of the civil laws.

II. The theological prudence includes therefore, first, the whole plan of church-government, and the arrangement of the ecclesiastical state; secondly, the ordinances relative to exterior ceremonies, and divine worship; and lastly, the discipline of the church, the errors, the schisms, the heresies, and dissensions that arise among Christians. The source of this prudence is a thorough knowledge of the essence of the Christian religion, and the method of drawing from it just consequences.

III. This discipline is likewise employed in deciding, wherein consists the difference between the clergy and the laity; or if there be, in fact, any real difference between them: if the church form a distinct state in the general system of government; and to whom belongs the right of deciding *circa sacra*; and what are the limits of the spiritual and temporal powers in this respect: wherein consists the hierarchy of the church, and what are its rights and privileges: to whom appertains the nomination of a priest, or other ecclesiastical, according to the divine ordinance: to whom is committed the right of preaching in public, of administering the sacraments, and of exercising the excommunicative power of expelling, or again admitting, any particular Christian, or even a whole country, into the pale of the church: the bans and interdicts; the exercise of sacred or theological studies; the schools, the seminaries, the universities and academies, the classes, the convents; and so of the rest: all subjects vigorously attacked and obstinately defended.

IV. The consistorial prudence examines likewise the liturgies, the ceremonies and religious customs, the breviaries, the rituals, the canticles, and other books of devotion adopted by the church; the formularies, the subjects of discipline, &c. &c. the creeds, the confessions of faith, the catechisms, and many other like matters; and lastly, the doubts and objects of controversy, that occasion the holding of synods and councils; the question, if the Pope be above the councils, or the councils above the Pope; the practice of elenchic theology, or the public elench; the separation and reunion of the church, which the Syncretists and Irenians dispute; the divorces more or less allowable; matrimonial, and consistorial matters, &c. &c.

V. All these subjects, and an infinity of others, which arise from, or have an immediate connection with these, require to be thoroughly considered: reduced into a regular system, explained and fixed on solid principles, and confirmed by just and pertinent examples. From all this results what is called Ecclesiastical Prudence. This science has

not yet been reduced into a system or formal discipline, and that principally because it has been constantly confounded with the ecclesiastical law: but that in reality differs as much from this, as political prudence differs from the common law.

OF THEOLOGIC PRUDENCE in the DIFFERENT FUNCTIONS of the MINISTRY.

I. INDEPENDENT of casuistical theology, and of the economy of the church in general, the theologian has, moreover, need of great sagacity in the particular exercise of his ministry; and many able divines have reduced this science into a system, and have given general precepts, and particular rules, for the conduct of the minister of the altar, in the different circumstances that may arise in this part of his duty. We shall decline the particular explanation of these different systems, as it would lead us into numberless *minutia*. *Conrad Porta* has wrote a work on the subject, intitled *Passionale Lutheri*; *Stoltzelius*, *Kortholt*, *Philip Hahn*, *Hartman*, and many other theologians, have wrote large volumes concerning it; but, above all, the treatise of *Dr. John Mayer*, which is called *Museum Ministri Ecclesiæ*, is to be consulted on this matter. We the more readily omit the names and titles of other works of this kind, as we have prescribed it to ourselves as a law, to avoid, as much as possible, these sorts of citations, seeing that the number of new books that are continually appearing frequently supercede their predecessors; and moreover, in this part of theology, each Christian communion has its particular authors, who treat it in conformity to the dogmas and principles which that communion adopts.

II. The humour of reducing every thing into system, has also taken place in this matter, which in fact appears to have no occasion for any peculiar discipline that could not be included under some other part of theology. But as this distinction is already made, it is our business to explain it, for the use of such as devote themselves to the altar. The prudential theology is, for them and their ministry, what political prudence is for a man of the world in the commerce of life. It is the art of attaining the end proposed: and as each condition in life has its particular pursuits, the divines have also naturally theirs, and the precepts of theologic prudence serve to conduct them to it.

III. But as the dogmas, the ceremonies, the rites and objects that the ministers of the different Christian communions propose to themselves, are by no means the same, each communion, each sect, does not follow, in this respect, the same rules and precepts, nor even part of the same principles. All that we can therefore do amidst this diversity of opinions, and contrariety of maxims, is to point out, in a few words, the principal objects that one or other of them comprehend in this part of their pastoral theology.

IV. The *Ascetic Theology*, for instance, treats of the various particular exercises of piety; and the principles, that it proposes with this regard, serve as guides to the minister of the altar, in his recommendation of the practice of it, as well as in many parts of his ecclesiastical duty. Fasts, pilgrimages, and many other matters of the same kind, belong to the province of ascetic theology, and which we will not absolutely reject, because we write for readers of all sorts of communions. Truth, however, obliges us to remark, that the ascetic theology of every communion is the offspring of principles falsely attributed to the Gospel, and belongs

belongs much more properly to superstition than religion. The monastic life, of which there is not the least trace to be found in the Holy Scriptures, and which is so contrary to the wisdom and goodness of God; the contemplative life which is employed merely in theoretic and barren speculations, and which is a continual impediment to the practice of the duties of a citizen, and of the social virtues; the corporal chastisements that the pious visionary inflicts on himself, and a thousand like absurdities, are the fruits of fanaticism, and the essence of ascetic theology.

V. Under this head may be also included, confession and absolution, which are modern inventions, and of which there is not the least vestige to be found in the Gospel, and which were unknown to Jesus Christ and his apostles; unless we would torture and disguise the text, and make a strange abuse of words, and of phrases the most simple: inventions, in short, that are more politic and lucrative than divine. Be that as it may, the ascetic theology prescribes general maxims relative to confession and absolution, and particular precepts for the priests of the confessional.

VI. The *Paracletic Theology*, on the contrary, is totally employed in preparing consolations against plagues and other public calamities and adversities, and against the most considerable evils that befall individuals. It considers, examines, and directs these consolations, and points out the proper method of applying them. As it is the business of ascetic theology to humble and intimidate the Christian, and to subject him to all sorts of pious and painful bodily exercises, so it is that of paracletic theology to reanimate his courage and his faith, and to administer consolation to his soul.

VII. The five doctrines of which we have here treated, to wit, the Homilistic, Catechetic, and Casuistic Theology, and the Confessorial and Theologic Prudence in the ordinary exercise of the ministry, form therefore what is called, in

a collective sense, *Pastoral Theology*; a science on which many authors, of all communions, have wrote vast treatises; in which complete courses are made at universities, by the faculties of theology; which is reduced into a regular system; and which, in fact, forms not one of the least parts of that science which is necessary to an able and faithful theologian who undertakes the cure of souls.

VIII. We think we have said enough to give an idea of those sciences that compose the general system of theology. We are not ignorant, however, that there are theologies established in the schools, still different in their genus and species: that they distinguish, for example, 1. The Theology of God, (*Theologia Dei*), 2. That of Jesus Christ, 3. That of the Holy Ghost, 4. That of Angels, and 5. That of Men: that they again sub-divide the Theology of God, 1. Into *Theologia Dei naturalis*, or *essentialis*, by which is shewn, that God perceives *simul et semel*, once and for ever, all that is contained in his essence; and 2. *Theologia Dei idealis* or *exemplaris*, which considers those things that must be revealed to mankind to work their salvation: this last article is again divided into *Archetypic Theology*, which teaches what comes, in this respect, immediately from God himself; and *Ectypic Theology*, which considers the theologic notions that man, as the image of God, is able to acquire by his own nature, that is, by the ability he has received from the Supreme Being, to know and adore him, and by the preaching of his divine word. But we should never have done, were we to relate all the distinctions, divisions, and subdivisions, &c. that men, fond of systematic forms, have introduced into all the sciences: divisions whose whimsical denominations busy and embarrass the mind that ought to be more usefully employed in attending to realities; and which constantly favour of that pedantry which insinuates itself, more or less, into the study of every science.

R E M

R E M

REMEMBRANCE. See MEMORY.

REMEMBRANCERS, anciently called clerks of the remembrance, certain officers in the exchequer, whereof three are distinguished by the names of the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of the first fruits. The king's remembrancer enters in his office all recognizances taken before the barons for any of the king's debts, for appearances or observing of orders; he also takes all bonds for the king's debts, &c. and makes out processes thereon. He likewise issues processes against the collectors of the customs, excise, and others, for their accounts; and informations upon penal statutes are entered and sued in his office, where all proceedings in matters upon English bills in the exchequer-chamber remain. His duty further is to make out the bills of compositions upon penal laws, to take the statement of debts; and into his office are delivered all kinds of indentures and other evidences which concern the assuring any lands to the crown. He, every year in *crastino annuarum*, reads in open court the statute for election of sheriffs; and likewise openly reads in court the oaths of all the officers, when they are admitted.

The lord treasurer's remembrancer is charged to make out processes against all sheriffs, escheators, receivers, and bailiffs, for their accounts. He also makes out writs of

fieri facias, and extent for debts due to the king, either in the pipe or with the auditors; and processes for all such revenue as is due to the king on account of his tenures. He takes the account of sheriffs; and also keeps a record, by which it appears whether the sheriffs or other accountants pay their proffers due at Easter and Michaelmas: and at the same time he makes a record, whereby the sheriffs or other accountants keep their prefixed days: there are likewise brought into his office all the accounts of customs, comptrollers, and accountants, in order to make entry thereof on record: also all freights and amercements are certified here, &c.

The remembrancer of the first-fruits takes all compositions and bonds for the payment of first-fruits and tenths; and makes out process against such as do not pay the same. REMINISCENCE, that power of the human mind, whereby it recollects itself, or calls again into its remembrance such ideas or notions as it had really forgot; in which it differs from memory, which is a treasuring up of things in the mind, and keeping them there, without forgetting them.

REMISSION, in physics, the abatement of the power or efficacy of any quality.

REMISSION, in law, &c. denotes the pardon of a crime, or the giving up the punishment due thereto.

RE-

REMITTANCE, in commerce, the traffic or return of money from one place to another, by bills of exchange, orders, or the like.

REMONSTRANCE, an expostulation or humble supplication, addressed to a king, or other superior, beseeching him to redress the inconveniences, or ill consequences of some order, or the like. This word is also used for an expostulatory counsel, or advice; or a gentle and handsome reproof, made either in general, or particular, to approve or correct some fault, &c.

REMORA, in ichthyology. See **ECHENEIS**.

ACTION OF REMOVING, in Scots law. See **LAW**, Tit. xiii. 16.

REMPLY, in heraldry, something filled up. The term is chiefly used to denote that the chief is quite filled up with a square piece of another colour, leaving only a bordure of the proper colour of the chief about the said piece. See **PLATE CXLVII. fig. 8.**

RENAL, something belonging to the reins or kidneys. See **ANATOMY**, p. 268.

RENCOUNTER, in the military art, an engagement of two little bodies or parties of forces; in which sense it stands in opposition to a pitched battle. See **BATTLE**.

RENCOUNTRE, or **RENCOTRE**, in heraldry, is applied to animals when they shew the head in front, with both eyes, &c. or when the face stands right forward, as if they came to meet the person before them.

RENDEZVOUS, a place appointed to meet in at a certain day and hour.

RENEALMIA, in botany. See **TELLANDRIA**.

RENEGATE, or **RENEGADO** a person who has apostatized or renounced the Christian faith, to embrace some other religion, particularly Mahometanism.

RENFREW, a town of Scotland, the capital of the county of Renfrew, situated on the river Clyde, forty-six miles west of Edinburgh.

RENIFORM, something resembling the figure or shape of kidneys.

RENITENCY, among philosophers, that force in solid bodies, whereby they resist the impulse of other bodies, or react as much as they are acted on. See **MECHANICS**.

RENNES, a city of France, capital of the province of Brittany, situated on the river Vilaine: W. long. 1° 45', N lat. 48° 5'.

RENT, in law, a sum of money, or other consideration, issuing yearly out of lands or tenements.

RENVERSE, **INVERTED**, in heraldry, is when any thing is set with the head downwards, or contrary to its natural way of standing. Thus, a chevron renversé is a chevron with the point downwards. They use also the same term when a beast is laid on its back.

RENUNCIATION, the act of renouncing, abdicating, or relinquishing any right, real or pretended.

RENUNCIATION by an heir, in Scots law. See **ADJUDICATION**.

REPARTEE a ready smart reply, especially in matters of wit, humour, or raillery.

REPEALING, in law, the revoking or annulling of a statute, or the like.

REPEAT, in music, a character shewing that what was last played or sung must be repeated or gone over again.

REPELLENTS, in medicine, remedies which drive back a morbid humour into the mass of blood from which it was unduly secreted.

The most remarkable in the class of repellents are the white of an egg, the lapis calaminaris, litharge of gum, radlead, tutty; pampholix, house-leek, putty, and cow web.

REPETITION, the reiterating of an action.

REPETITION, in rhetoric, a figure which gracefully and emphatically repeats either the same word, or the same sense in different words.

REPLETION, in medicine, a plenitude or plethora. See **PLETHORA**.

Right of REPLEDGING, in Scots law. See **LORD of REGALITY**.

REPRESENTATION, in the drama, the exhibition of a theatrical piece, together with the scenes, machines, &c. See **COMPOSITION**.

REPRESENTATIVE, one who personates or supplies the place of another, and is invested with his right and authority. Thus the house of commons are the representatives of the people in parliament.

REPRIEVE, in law, is suspending or deferring the execution of the law upon a prisoner for a certain time; or a warrant from the king for deferring the execution of a person condemned.

REPRISALS, a right which princes claim of taking from their enemies any thing equivalent to what they unjustly detain from them.

REPROBATION, in theology, a decree by which God is supposed, either from all eternity, or from the creation of the world, to consign over to eternal misery the greatest part of mankind, and to save none of the human race, except those whom he made the heirs of glory by election.

REPROBATOR, in Scots law. See **LAW**, Tit. xxxi. 14.

REPRODUCTION, the act whereby a thing is produced anew, or grows a second time.

The reproduction of several parts of lobsters, crabs, &c. is one of the greatest curiosities in natural history. It seems, indeed, inconsistent with the modern system of generation, which supposes the animal to be wholly formed in the egg; that, in lieu of an organical part of an animal cut off, another should arise perfectly like it: the fact, however, is too well attested to be denied. The legs of lobsters, &c. consist each of five articulations; now when any of the legs happen to break, by any accident, as by walking, &c. which frequently happens, the fracture is always found to be at the future near the fourth articulation; and what they thus lose, is exactly reproduced in some time afterwards. That is, a part of the leg shoots out, consisting of four articulations, the first whereof has two claws, as before; so that the loss is entirely repaired.

If the leg of a lobster be broken off by design at the fourth or fifth articulation, what is thus broke off is always reproduced. But, if the fracture be made in the first, second or third articulation, the reproduction is not so certain. And it is very surprising, that, if the fracture be made at these articulations, at the end of two or three days all the other articulations are generally found broke off to the fourth, which, it is supposed, is done by the creature itself, to make the reproduction certain. The part reproduced is not only similar to that re-trenched, but also, in a certain space of time, grows equal to it. Hence it is that we frequently see lobsters which have their two large legs unequal in all proportions; and, if the part reproduced be broken off, a second will succeed.

REPTILES, in natural history, a kind of animals denominated from their creeping or advancing on the belly. Or reptiles are a genus of animals and insects, which, instead of feet, rest on one part of the body, while they advance forward with the rest.

Such are earthworms, snakes, caterpillars, &c.

REPUBLIC, commonwealth, a popular state or government; or a nation where the people have the government in their own hands.

REPUBLIC of letters, a phrase used collectively of the whole body of the people of study and learning.

REPUDIATION, in the civil law, the act of divorcing. See **DIVORCE**.

REPULSION, in physics, that property in bodies, whereby, if they are placed just beyond the sphere of each other's attraction, they mutually fly from each other. See **ELECTRICITY**, and **MECHANICS**.

REQUEST, in law, a supplication or petition preferred to a prince, or to a court of justice, begging relief in some comfortable cases where the common law grants no immediate redress.

Court of REQUESTS, an ancient court of equity, instituted about the nineteenth year of Henry VII. See **COURT**.

In the fortieth and forty-first years of queen Elizabeth, it was adjudged upon solemn argument, in the court of common pleas, that the court of request was then no court of equity.

REQUIEM, in the Romish church, a mass sung for the rest of the soul of a person deceased. See **MASS**.

REQUISITION, in Scots law. See **LAW**, Tit. xv. 8.

RESARCELE'E, in heraldry, is where a slender cross is charged upon another, as represented in Plate CXLVII. fig. 6.

RESCHET, the capital of the province of Gilan, in Persia, situated on the south-west coast of the Caspian sea.

RESCISION, in the civil law, an action intended for the annulling, or setting aside, any contract, deed, &c.

RESCRIPT, an answer delivered by an emperor, or a pope, when consulted by particular persons, on some difficult question or point of law, to serve as a decision thereof.

RESEDA, in botany, a genus of the dodecandria trigynia class. The calix consists of one deeply cut leaf; the petals are lacinated; and the capsule has one cell. There are 11 species, two of them natives of Britain, *viz.* the lutea, or bafe-rocket; and the luteola, wild woad, or dyers weed.

RESERVATION, in law, an action or clause whereby something is reserved, or secured to one's self.

Mental RESERVATION, a proposition, which, strictly taken, and according to the natural import of the terms, is false; but, if qualified by something concealed in the mind, becomes true.

Body of RESERVE, or *Corps de RESERVE*, in military affairs, the third or last line of an army, drawn up for battle; so called because they are reserved to sustain the rest, as occasion requires; and not to engage, but in case of necessity.

RESERVOIR, a place where water is collected and reserved, in order to be conveyed to distant places through pipes, or supply a fountain, or jet d'eau.

RESET OF THEFT, in Scots law. See **LAW**, Tit. xxxiii. 29.

RESIDENT, a public minister, who manages the affairs of a kingdom or state, at a foreign court.

They are a class of public ministers inferior to ambassadors or envoys; but, like them, are under the protection of the law of nations.

RESIDUE, the remainder or balance of an account, debt, or any thing else.

RESIN. See **CHEMISTRY**, p. 94.

RESIGNATION, in Scots law. See **LAW**, Tit. xiv. 7.

RESISTANCE, or **RESISTING FORCE**, in philosophy, denotes, in general, any power which acts in an opposite direction to another, so as to destroy or diminish its effect. See **MECHANICS**, **HYDROSTATICS**, and **PNEUMATICS**.

RES JUDICATA, in Scots law. See **LAW**, Tit. xxxii. 4.

RES Publica, in Scots law. See **LAW**, Tit. viii. 2.

RES Universitatis, in Scots law. See **LAW**, *ibid.*

RES Sacre, in Scots law. See **LAW**, *ibid.*

RESOLUTION, in chemistry, &c. the reduction of a mixed body into its component parts, or first principles, by a proper analysis. See **CHEMISTRY**, p. 100.

RESOLUTION, in medicine, that coction or alteration of the crude peccant matter of any disease, either by the natural strength of the patient, or of its own accord, or by the application of remedies, whereby its bulk, figure, cohesion, &c. are so far changed, as that it ceases to be morbid, and becomes laudable.

RESOLVENTS, in medicine, remedies proper to resolve and dissipate tumours and gatherings, to soften indurations, and, by their tenuity and warmth, evacuate redundant and peccant humours through the pores. Under this class come various unguents, emplaisters, &c.

RESONANCE, **REOUNDING**, in music, &c. a sound returned by the air, inclosed in the bodies of stringed musical instruments, as lutes, &c. or even in the bodies of wind instruments, as flutes, &c. See **MUSIC**, and **PNEUMATICS**.

RESPIRATION, the act of respiring or breathing the air. See **ANATOMY**, p. 281.

RESPITE, in law, &c. signifies a delay, forbearance, or prolongation of time, granted any one, for the payment of a debt or the like.

RESPONDENT, in the schools, one who maintains a thesis, in any art or science; who is thus called, from his being to answer all the objections proposed by the opponent.

RESPONSE, an answer or reply. A word chiefly used in speaking of the answers made by the people to the priest, in the litany, the psalms, &c.

RESSAULT, in architecture, is the effect of a body which either projects or sinks back; that is, stands more out or in than another, so as to be out of the line or level with it.

RESSORT, a French word, sometimes used by English authors, to signify the jurisdiction of a court, and particularly one from which there is no appeal.

Thus it is said, that the house of lords judge en dernier ressort, or in the last ressort.

REST, the continuance of a body in the same place, or its continual application or contiguity to the same parts of the ambient or contiguous bodies; and therefore is opposed to motion.

REST, in poetry, is a short pause of the voice in reading, being

being the same with the *cæsura*, which, in alexandrine verses, falls on the sixth syllable; but in verses of ten or eleven syllables, on the fourth.

RESTAURATION, the act of re establishing or setting a thing into former good state.

RESTITUTION, in a moral and legal sense, is restoring a person to his right; or returning something unjustly taken or detained from him.

RESTITUTION of medals, or RESTITUTED MEDALS, is a term used by antiquaries, for such medals as were struck by the emperors, to retrieve the memory of their predecessor.

Hence, in several medals we find the letters *REST*. This practice was first begun by Claudius, by his striking afresh several medals of Augustus. Nero did the same; and Titus, after his father's example, struck restitutions of most of his predecessors. Gallienus struck a general restitution of all the preceding emperors, on two medals, the one bearing an altar, the other an eagle, without the *REST*.

RESTIVE, or *RESTY*, in the manege, a stubborn, unruly, ill-broken horse, that stops, or runs back, instead of advancing forward.

RESTORATION, the same with *restauration*. See *RESTAURATION*.

In England, the return of king Charles II. in 1660, is, by way of eminence, called the *Restoration*; and the 29th of May is kept as an anniversary festival, in commemoration of that event, by which the regal and episcopal government was restored.

RESTORATIVE, in medicine, a remedy proper for restoring and retrieving the strength and vigour both of the body and animal spirits.

All under this class, says Quincy, are rather nutritive than medicinal; and are more admittit to rectify the wastes of the constitution, than to alter and rectify its disorders.

RESTRICTION, among logicians, is limiting a term, so as to make it signify less than it usually does.

RESTRINGENT, in medicine, the same with *alstringent*. See *ASTRINGENTS*.

RESULT, what is gathered from a conference, inquiry, meditation, or the like; or the conclusion and effect thereof.

RESURRECTION, in theology, rising again from the dead; or a person's returning to a second life, with new bodily organs, adapted to the state of its new existence.

One of the great arguments for the truth of Christianity is drawn from the resurrection of our Saviour; the circumstances of which are handed down to us in so plain and distinct a manner by the evangelists, as make the evidence of this important truth amount to a demonstration.

Christians generally believe, that at the day of judgement, the very identical body they have now, with the same flesh, blood, and bones, will be raised from the dead.

RESUSCITATION, the same with *resurrection* and *revivification*. See the preceding article.

The term *resuscitation*, however, is more particularly used by chemists, for the reproducing a mixed body from its ashes: an art to which many have pretended, as to reproduce plants, &c. from their ashes.

RETAIL, in commerce, is the selling of goods in small parcels, in opposition to wholesale. See *COMMERCE*.

RETAINER, a servant who does not continually dwell in the house of his master, but only attends upon special occasions.

RETAINING FEE, the first fee given to a serjeant or counsellor at law, in order to make him sure, and prevent his pleading on the contrary side.

RETALIATION, among civilians, the act of returning like for like.

RETARDATION, in physics, the act of diminishing the velocity of a moving body. See *MECHANICS*.

RETE MIRABLE, in anatomy, a small plexus, or network of vessels in the brain, surrounding the pituitary gland. See *ANATOMY*, p. 286.

RETENTION, is defined, by Mr Locke, to be a faculty of the mind; whereby it keeps, or retains, those simple ideas it has once received, by sensation or reflection. See *METAPHYSICS*.

RETENTION is also used, in medicine, &c. for the state of contraction in the solids or vascular parts of the body, which makes them hold fast their proper contents. In this sense, retention is opposed to evacuation and excretion.

RETIARI, in antiquity, a kind of gladiators, thus denominated from a net which they made use of against their antagonists, who were called *secutores*, and sometimes *mirmillones*.

This net they carried under their buckler, and when opportunity served, cast it over the head of their antagonist, and in this condition killed him with a trident which they bore in the other hand.

RETFORD, a borough-town of Nottinghamshire, situated twenty-five miles north of Nottingham. It sends two members to parliament.

RETICULA, or *RETICULE*, in astronomy, a contrivance for the exact measuring the quantity of eclipses.

The reticule is a little frame, consisting of thirteen fine silken threads, equidistant from each other, and parallel, placed in the focus of object-glasses of telescopes; that is, in the place where the image of the luminary is painted in its full extent: of consequence, therefore, the diameter of the sun or moon is hereby seen divided into twelve equal parts or digits; so that, to find the quantity of the eclipse, there is nothing to do but to number the luminous and dark parts. As a square reticule is only proper for the diameter, not for the circumference, of the luminary, it is sometimes made circular by drawing six concentric equidistant circles. This represents the phases of the eclipse perfectly.

Corpus RETICULARE, in anatomy. See *ANATOMY*, p. 255.

RETINA, in anatomy. See *ANATOMY*, p. 289.

RETINUE, the attendants or followers of a prince or person of quality, chiefly in a journey.

RETIRADE, in fortification, a kind of retrenchment made in the body of a bastion, or other work, which is to be disputed, inch by inch, after the defences are dismantled. It usually consists of two faces, which making a re-entering angle, when a breach is made in a bastion, the enemy may also make a *retirade* or new fortification behind it.

RETLINGEN, an imperial city of Germany, in the circle of

of Swabia and duchy of Wirtemberg, situated in E. long. 6°, N. lat. 48° 18'.

RETORT, in chemistry. See **CHEMISTRY**, p. 110.
RETRACTS, among horsemen, pricks in a horse's feet, arising from the fault of the farrier in driving nails that are weak, or in driving them ill pointed, or otherwise amiss.

RETRENCHMENT, literally signifies something cut off or taken from a thing; in which sense it is the same with subtraction, diminution, &c.

RETRENCHMENT, in the art of war, any kind of work raised to cover a post, and fortify it against the enemy, such as fascines loaded with earth, gambions, barrels of earth, sand bags, and generally all things that can cover the men and stop the enemy. See **FORTIFICATION**.

RETRIBUTION, a handsome present, gratuity, or acknowledgment, given instead of a formal salary or hire to persons employed in affairs that do not so immediately fall under estimation, nor within the ordinary commerce in money.

RETROCESSION, the act of going backwards; more usually called retrogression, or retrogradation. See the next article.

RETROCESSION of the equinox. See **ASTRONOMY**, p. 562.

RETROGRADATION, the act or effect of a thing moving backwards.

Retrograde motion of the planets. See **ASTRONOMY**, p. 448.

RETROMINGENTS, in natural history, a class or division of animals, whose characteristic it is that they stale, or make water, backwards, both male and female.

REVE, **REEVE**, or **GREVE**, the bailiff of a franchise, or manor, thus called, especially in the west of England. Hence three-reve, sheriff, port-greve, &c.

REVELLE, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the sentries are to forbear challenging.

REVEL, a port-town of Livonia, situated at the south entrance of the gulph of Finland: E. long. 24°, N. lat. 59°.

REVELATION, the act of revealing, or making a thing public that was before unknown: it is also used for the discoveries made by God to his prophets, and by them to the world; and more particularly for the books of the Old and New Testament. See **BIBLE** and **RELIGION**.

REVELATION of St John. See **APOCALYPSE**.

REVELS, entertainments of dancing, masking, acting comedies, farces, &c. anciently very frequent in the inns of court, and in noblemen's houses, but now much disused. The officer who has the direction of the revels at court, is called the master of the revels.

REVENUE, the annual income a person receives from the rent of his lands, houses, interest of money in the stocks, &c.

REVENUE, in hunting, a fleshy lump formed chiefly of a cluster of whitish worms on the head of deer, supposed to occasion their casting their horns by gnawing them at the roots.

REVERBERATION, in physics, the act of a body repelling or reflecting another after its imping'g thereon.

REVERBERATION, in chemistry, denotes a kind of circulation of the flame by means of a reverberatory. See **CHEMISTRY**, p. 112.

REVERBERATORY, or **REVERBERATING FURNACE**. See **CHEMISTRY**, p. 112.

REVEREND, a title of respect given to ecclesiastics.

REVERIE, the same with delirium, raving, or distraction. It is used also for any ridiculous, extravagant imagination, action, or proposition, a chimera or vision. But the most ordinary use of the word, among English writers, is for a deep disorderly musing or meditation.

REVERSE of a medal, coin, &c. denotes the second or back side, in oppositi' n to the head or principal figure.

REVERSION, in Scots law. See **LAW**. Tit. xv. 1.

REVIVIFICATION, in chemistry. See **RESUSCITATION**.

REVOLUTION, in politics, signifies a grand change or turn in government. In which sense, the revolution is used, by way of eminence, for the great turn of affairs in England, in the year 1688, when king James II. abdicating the throne, the prince and princess of Orange were declared king and queen of England, &c. In geometry, the revolution of any figure, is its motion quite round a fixed line, as an axis.

The revolution of a planet, or comet, round the sun, is nothing but its course from any point of its orbit till its return to the same. See **ASTRONOMY**.

REVULSION, in medicine, turning a flux of humours from one part to another, by bleeding, cupping, friction, sinapisms, blisters, fomentations, bathings, issues, setons, &c. for purging of the bowels, &c. See **MEDICINE**.

REYGATE, or **RYGATE**, a borough of Surry, twenty-two miles south-west of London. It sends two members to parliament.

REZANSKOI, the capital of the province of Rezan, in Russia: east long. 41°, north lat. 55°.

RHAGADES, in medicine, denotes chaps or clefts in any part of the body; arising either from any aridity of the parts, or acrimony of the humours.

RHAMNUS, in botany, a genus of the pentandria monogynia class. The calix is tubulose, the scales fortifying the stamina; it has no corolla: and the fruit is a berry. There are 20 species, none of them natives of Britain.

RHAMPHASTOS, in ornithology, a genus belonging to the order of picæ. The bill is large, convex, and serrated outwards: each mandible is crooked inwards at the point; the nostrils are situate behind the base of the bill; the tongue resembles a feather; and the feet of most of them are fitted for climbing. There are eight species, principally distinguished by their colour.

RHAPSODI, *rhapsodisti*, in antiquity, persons who made a business of singing pieces of Homer's poems. Cupper informs us, that the rhapsodi were clothed in red when they sung the Iliad, and in blue when they sung the Odyssey. They performed on the theatres, and sometimes strove for prizes in contests of poetry, singing, &c. But there seems to have been other rhapsodi of more antiquity than those people, who composed heroic poems or songs in praise of heroes and great men, and sung their own compositions from town to town for a livelihood, of which profession Homer himself is said to be.

RHAPSODOMANCY, an ancient kind of divination performed by pushing on a p'ssage of a poet at hazard, and reckoning on it as a revelation of what was to come to pass.

RHAPSODY, in antiquity, a discourse in verse sung or rehearsed by a rhapsodist. Others will have rhapsody

to signify a collection of verses, especially those of Homer, which having been a long time dispersed in pieces and fragments, were at length, by Philostratus's order, digested into books called rhapsodies. Hence, among moderns, rhapsody is also used for an assemblage of passages, thoughts, and authorities, raked together from divers authors, to compose some new piece.

RHE, or REE, a little island in the bay of Biscay, near the coast of Aunis in France: W. long. $1^{\circ} 30'$, N. lat. $46^{\circ} 14'$.

RHEIMS, or REIMS, a city of France, capital of the province of Champagne, one of the most elegant cities in France, situated seventy-five miles north-east of Paris: E. long. 4° , N. lat. $49^{\circ} 20'$.

RHETERIANS, a sect of heretics in Egypt, so denominated from Rhetorius their leader. The distinguishing doctrine of this heresiarch, as represented by Philastrius, was, that he approved of all the heresies before him, and taught that they were all in the right.

RHETORIC, the art of speaking copiously on any subject, with all the advantage of beauty and force.

Lord Bacon defines rhetoric, very philosophically, to be the art of applying and addressing the dictates of reason to the fancy, and of recommending them there so as to affect the will and desires. The end of rhetoric, the same author observes, is to fill the imagination with ideas and images which may assist nature without oppressing it. Vossius defines rhetoric, The faculty of discovering what every subject affords of use for persuasion. Hence, as every author must invent arguments to make his subject prevail; dispose those arguments, thus found out, in their proper places; and give them the embellishments of language proper to the subject; and, if this discourse be intended to be delivered in public, utter them with that decency and force which may strike the hearer; rhetoric becomes divided into four parts, invention, disposition, elocution, and pronunciation.

Rhetoric and oratory differ from each other as the theory from the practice; the rhetorician being he who describes the rules of eloquence, and the orator he who uses them to advantage. Ordinarily however, the two are used indifferently for each other. See COMPOSITION.

RHEUM, a thin serous humour, occasionally oozing out of the glands about the mouth and throat.

RHEUM in botany. See BOTANY, p. 642.

RHEUMATISM, in medicine. See MEDICINE, p. 124.

RHEXIA, in botany, a genus of the diandria monogynia class. The calyx consists of four segments, and the corolla of four petals inserted into the calyx: the anthers are declined; and the capsule has four cells. There are three species, none of them natives of Britain.

RHINANTHUS, in botany, a genus of the didynamia angiospermia class. The calyx is swelled, and has four segments; the capsule is obtuse compressed, and bilocular. There are six species, only one of which, viz. the cristagalli, yellow rattle, or cock's comb, is a native of Britain.

RHINE, a great river rising in the country of the Grisons, in Switzerland, and, running north, continues its course till it forms the lake of Constance, from whence it turns west, and having visited Basil, runs north, dividing Suabia from Alsacia; from thence it runs through the Palatinate and receiving the Neckar, the Maine, and the Mo-

selle, continues its course north by Mentz, &c. After entering the Netherlands at Skenkinchans, it is divided into several channels, the two largest whereof obtain the names of the Lech and the Waal, which running through the United Provinces discharge themselves into the German sea below Rotterdam.

RHINE lower circle consists of the Palatinate of the Rhine and the three ecclesiastical electorates, viz. those of Cologne, Mentz, and Triers.

RHINE upper circle consisted of the Landgraves of Alsacia and Hesse, comprehending the Wetteraw: but only Hesse can be accounted a part of Germany at present, France having united Alsace to that kingdom.

RHINEBURG, a town of Germany in the circle of the lower Rhine and electorate of Cologne, situated fifteen miles east of Gelder.

RHINEFIELD, the name of two towns of Germany, one whereof is situated in the circle of Suabia, on the Rhine, eight miles east of Basil; the other is the capital of the county of Rhinefield, situated in the circle of the Upper Rhine, sixteen miles north-west of Mentz.

RHINOCEROS, in zoology a genus of quadrupeds belonging to the order of bellua, of which there is but one species, viz. the unicornis, a native of Africa and India. It has two fore-teeth in each jaw, situate at a great distance from each other, and blunt, and a solid conical horn upon the nose. This, of all quadrupeds, approaches nearest to the elephant in size, the body being nearly as bulky, but the legs much shorter. A full-grown rhinoceros is fourteen feet high: and the legs are so short with all this height, that the belly comes near the ground: the head is very large and oblong, of an irregular figure, broad at top, and depressed towards the snout: the ears resemble those of a hog: the eyes are very small, and situated at a small distance from the extremity of the snout: on the upper part of the snout, near the extremity, stands the horn, growing to about two feet and a half in length, bent a little back, of a black colour and vastly firm and hard: the skin is remarkably thick and hard, so that the creature could not turn its body in any direction but for the joints and folds in it: the tail is short, and furnished with some long and extremely thick black hairs. The rhinoceros feeds upon thorns and brushwood; like the sow, he wallows in the mire. He is gentle and inoffensive, except when he is injured. But, when irritated, he even overturns large trees in his fury.

RHINOCEROS BIRD. See BUCEROS.

RHIZOPHORO, in botany, a genus of the dodecandria monogynia class. Both calyx and corolla consist of four segments; and there is but one long seed, fleshy at the base. The species are seven, none of them natives of Britain.

RHODES, the capital of an island of that name, situated in the Mediterranean sea, in E. long. 28° , and between 36° and 37° N. lat.

RHODIOLA, in botany, a genus of the diœcia enneandria class. The calyx of the male consists of four segments, and the corolla of four petals; the calyx of the female has four segments; it has no corolla, but four nectaria and four pistils; and it has four capsules, containing many seeds. There is but one species, viz. the rosea, or rose-wort, a native of Britain.

RHODODENDRUM, in botany, a genus of the decan-

dria monogynia class. The calix has five segments; the corolla is somewhat funnel-shaped; the stamina are declined; and the capsule has five cells. There are six species, none of them natives of Britain.

RHOMBOIDES, in geometry, a quadrilateral figure whose opposite sides and angles are equal, but is neither equilateral nor equiangular.

RHOMBOIDES, in anatomy. See **ANATOMY**, p. 193.

RHOMBOIDIA, in natural history, the name of a genus of spars, given them from their being of a rhomboidal form.

RHOMBUS, in geometry, an oblique-angled parallelogram, or a quadrilateral figure whose sides are equal and parallel, but the angles unequal, two of the opposite ones being obtuse, and the other two acute.

RHOMBUS, in ichthyology. See **PLEURONECTES**.

RHONE, one of the largest rivers in France; which rising in one of the Alps of Switzerland, passes through the lake of Geneva, visits that city, and then runs south-west to Lyons, where joining the river Soane, it continues its course due south, passing by Orange, Avignon, and Arles, and falls into the Mediterranean a little westward of Marseilles.

RHUBARB. See **BOTANY**, p. 642.

RHUMB. **RUMB**, or **RUM**, in navigation, a vertical circle of any given place, or the intersection of such a circle with the horizon; in which last sense, rhumb is the same with a point of the compass. See **NAVIGATION**.

RHUMB LINE, is also used for the line which a ship describes when sailing in the same collateral point of the compass, or oblique to the meridians. See **NAVIGATION**.

RHUS, in botany, a genus of the pentandria trigynia class. The calix consists of five segments, and the corolla of five petals; and the berry contains but one seed. The species are 16, none of them natives of Britain.

RHYME, in poetry, the similar sound, or cadence and termination of two words which end two verses, &c. Or rhyme is a similitude of sound between the last syllable or syllables of a verse, succeeding either immediately, or at a distance of two or three lines.

There is no rule in poetry, says Du Bos, whose observance costs so much trouble, and is productive of less beauties in verse, than that of rhyming. Rhyme frequently maims, and almost always enervates the sense of the discourse; for one bright thought which the passion of rhyming throws in our way by chance, is, without doubt, every day the cause of a hundred others that people would blush to make use of were it not for the richness or novelty of the rhyme with which these thoughts are attended.

RHYTHM, in music, the variety in the movement, as to the quickness or slowness, length or shortness, of the notes. Or it may be defined more generally, the proportion which the parts of the motion have to each other. See **MUSICK**.

RIBBAN, or **RIBBON**, in heraldry, the eighth part of a bend, like that represented in Plate CXLVII. fig. 10.

RIBBAND, or **RIBBON**, a narrow sort of silk, chiefly used for head-ornaments, badges of chivalry, &c.

RIBES, in botany, a genus of the pentandria monogynia class. It has five stamina, and five petals, both inserted into the calix; the stylus is bifid, and the berry contains many seeds. There are eight species, three of them

natives of Britain, viz. the rubrum, or currants; the alpinum, or sweet mountain currants; and the nigrum, or black currants.

RIBS, in anatomy. See **ANATOMY**, p. 173.

RICCIA, in botany, a genus of the cryptogamia algæ class. There are four species, all natives of Britain.

RICE, in botany. See **ORYZA**.

RICHARDIA, in botany, a genus of the hexandria monogynia class. The calix has six segments, and the corolla one subcylindrical petal; and the seeds are three. There is but one species, a native of Vera Cruz.

RICHLIEU, a town of France, in the province of Orleans and territory of Poitou, situated twenty-six miles north of Poitiers.

RICHMOND, a village in the county of Surry, ten miles west of London, formerly the residence of the kings of England.

RICHMOND is also a borough town of Yorkshire, thirty-three miles north-west of York. It sends two members to parliament.

RICINUS, in botany, a genus of the monœcia monadelphica class. The calix of the male has five segments; it has no corolla, but the stamina are numerous: The calix of the female has three segments; it has no corolla; the styli are three, and bifid; and the capsule has three cells, and one seed. There are three species, none of them natives of Britain.

RICKETS, in medicine. See **MEDICINE**, p. 169.

RIDGE, in agriculture, a long piece of rising land, between two furrows. See **AGRICULTURE**, p. 57.

RIDGLING, or **RIDGEL**, among farriers, &c. the male of any beast that has been but half geld.

RIDICULE, in matters of literature, is that species of writing, which excites contempt with laughter.

RIDING, a division of Yorkshire; of which there are three, viz. the east, west, and north ridings.

In all indictments in that county, both the town and riding must be expressed.

RIEF, in Scots law. See **ROBBERY**.

RIGA, a port-town of Livonia, one of the best harbours and trading towns in the Baltic: E. long. 24°, N. lat. 57°.

RIGGING of a ship, is all her cordage and ropes, belonging to her masts, yards, &c.

RIGHT, in geometry, signifies the same with straight: thus, a straight line is called a right one.

RIGIDITY, in physics, denotes a brittle hardness. It is opposed to ductility, malleability, and softness.

RIGOR, in medicine, a convulsive shuddering, from severe cold, an ague-fit, or other disorder.

RIMINI, a port-town of Italy, in the territories of the pope, and province of Romania, situated on the gulph of Venice: E. long. 13° 30'. and N. lat. 44° 8'.

RIND, the skin of any fruit that may be cut off or pared.

Rind is also used for the inner bark of trees, or that whitish soft substance which adheres immediately to the wood.

RING, an ornament of gold, silver, &c. made of a circular form, and generally worn on the finger.

RING BONS, in farriery, a hard callous substance, growing in the pattern of a horse, above the coronet: it is thus called from its growing quite round like a ring. See **FARRIERY**.

RIO GRANDE, a river of Terra Firma, which rising almost under the equator, and running north, falls into the north sea between Carthage and St Martha.

RIO GRANDE is also a river of Africa, which runs from east to west through Negroland, and falls into the Atlantic ocean, in 11° N. lat.

RIO JANEIRO, a river of South America, which rises in the mountains west of Brazil, and falls into the Atlantic ocean almost under the tropic of capricorn.

RIOT, in law, is where three or more persons, assembled together, commit some unlawful act, with force and violence, to the disturbance of the peace; as beating some person, forcibly entering upon the possession of the lands, houses, &c. of another, or breaking down inclosures, houses, &c.

By stat. 1. Geo. I. cap. v. if any persons to the number of twelve or more, unlawfully and riotously assembled, continue together for an hour, after being required, by a justice of the peace, or other magistrate, to disperse, they shall be deemed guilty of felony without benefit of clergy. However, prosecutions upon this statute, must be begun within one year after the offence is committed.

RIPPON, a borough-town of Yorkshire, twenty one miles north-west of York. It sends two members to parliament.

RISK, in gaming, &c. See **CHANCE**.

RITE, among divines, denotes the particular manner of celebrating divine service, in this or that country.

RITORNELLO, or **REPEAT**, in music, the burden of a song, or the repetition of the first or other verses of a song at the end of each stanza or couplet.

RITUAL, a book directing the order and manner to be observed in celebrating religious ceremonies, and performing divine service in a particular church, diocese, order, or the like.

RIVAL, a term applied to two or more persons, who have the same pretensions, and which is properly applied to a competitor in love, and figuratively to an antagonist in any other pursuit.

RIVER, a current or stream of fresh water flowing in a bed or channel from its source into the sea.

The great as well as the middle-sized rivers proceed either from a confluence of brooks and rivulets, or from lakes; but no river of considerable magnitude flows from one spring, or one lake, but is augmented by the accession of others. Thus the Wolga receives above two hundred rivers and brooks before it discharges itself into the Caspian Sea; and the Danube receives no less, before it enters the Euxine Sea.

RIVINIA, or **RIVINA**, in botany, a genus of the tetrandria monogynia class. The corolla consists of four permanent petals; it has no calix; and the berry contains one rough seed. There are two species, none of them natives of Britain.

RIVULET, a diminutive of river. See **RIVER**.

ROACH, in ichthyology. See **CYPRINUS**.

ROANOAK, an island in North America, near the coast of Albemarle-county, in North Carolina: W. long. 75°, N. lat. 35° 40'.

ROB, in pharmacy, the juices of fruits purified and inspissated till it is of the consistence of honey.

Rob of alder-berries is thus prepared: Take two quarts of the juice of ripe alder-berries, and half a pound of re-

fined sugar. Evaporate over a gentle fire, or in a water bath, till it is of a due consistence.

ROBBERY, in law, a felonious taking away another's man's goods, from his person, presence, or estate, by putting him in fear. See **LAW**, Tit. xxxiii. 20.

ROBINIA, in botany, a genus of the diadelphia decandria class. The vexillum is open, reflected, and roundish; the calix has four teeth, the uppermost being emarginated. There are six species, none of them natives of Britain.

ROBORANTS, in pharmacy, medicines which strengthen the parts, and give new vigour to the constitution.

ROCHEFOUCAUT, a town of Orleansois, in France, fifteen miles east of Angoulême.

ROCHELLE, a city and port-town of Orleansois, in France: W. long. 1° 5', N. lat. 46° 7'.

ROCHESTER, a city of Kent, situated on the river Medway, thirty miles east of London, and twenty-two west of Canterbury.

ROCHFORD, a market-town of Essex, thirty-three miles east of London, and fifteen south-east of Chelmsford.

ROCHFORD, a port-town of Guienne, in France, twenty-three miles south of Rochelle: W. long. 1°, N. lat. 46°.

It is one of the stations of the French navy, having a commodious harbour, well secured by forts and batteries.

ROCK, a large mass or block of hard stone rooted in the ground.

Rock-crystal, otherwise called *sparg-crystal*, in natural history, a name given to the third order of crystals, from their being affixed to a rock or other solid body.

This kind of crystal is the most common of all others, and is what the generality of authors describe under the name of crystal of the shops, being that kept for medicinal purposes.

The clearest, purest, and most transparent that can be had, ought to be chosen; and to prove its genuineness, it may be tried with aqua fortis, true crystal making no effervescence with that menstruum.

ROCKET, an artificial fire-work, consisting of a cylindrical case of paper, filled with a composition of certain combustible ingredients; which, being tied to a stick, mounts into the air, to a considerable height, and there bursts.

ROCKINGHAM, a market-town of Northamptonshire, situated nineteen miles north of Northampton.

ROD, a land measure of sixteen feet and a half: the same with perch and pole.

Black Rod, a staff carried by the king's gentleman-usher, as a badge of his office; this rod or staff is black, and has a lion in gold on its top. See **USHER**.

Fishing Rod, a long taper rod or wand, to which the line is fastened for angling.

ROE, the spawn or seed of fish. That of the male fishes is usually distinguished by the name of *soft roe*, or *milt*; and that of the female, by *hard roe*, or *spawn*.

So inconceivably numerous are these ovula, or small eggs, that M. Petit found 342144 of them in a carp of eighteen inches: but M. Leewenhoeck found in a carp no more than 21629. This last gentleman observes, that there are four times this number in a cod, and that a common one contains 9344000 eggs.

ROE, in zoology. See **CERVUS**.

ROELLA,

ROELLA, in botany, a genus of the pentandria monogynia class. The corolla is funnel-shaped; the stigma is bifid, and the capsule is cylindrical, and has two cells. The species are two, none of them natives of Britain.

ROER, the name of two rivers in Germany, one of which rises on the confines of Hesse, and falls into the Rhine, a little below Dusseldorf; the other rises in the duchy of Juliers, and falls into the Maese at Roermond.

ROGA, in antiquity, a present which the emperors made to the senators, magistrates, and even to the people; and the popes or patriarchs to their clergy.

These roges were distributed by the emperors on the first day of the year, on their birth day, or on the natalis dies of the cities; and by the popes and patriarchs, in passion-week.

Roga is also used for the common pay of the soldiers.

ROGATION, in the Roman jurisprudence, a demand made by the consuls or tribunes of the Roman people, when a law was proposed to be passed. Rogatio is also used for the decree itself made in consequence of the peoples giving their assent to this demand, to distinguish it from a senatus-consultum, or decree of the senate.

ROGATION WEEK, the week immediately preceding Whitsunday, so called from the three fasts therein, on Monday, Tuesday, and Wednesday, which are also called rogations, or rogation days, from the extraordinary prayers and supplications at this time offered to God by devout Christians to appease his anger and deprecate his judgments.

ROGUE, in law, an idle sturdy beggar; who by ancient statutes is for the first offence called a rogue of the first degree, and punished by whipping, and boring through the grille of the right ear with a hot iron; and for the second offence, is termed a rogue of the second degree, and, if above eighteen years of age, ordered to be executed as a felon.

ROHAN, a town of France, in the province of Brittany, situated twenty miles north of Vannes.

ROLL, in manufactures, something wound and folded up in a cylindrical form.

ROLL, in law, signifies a schedule or parchment which may be rolled up by the hand into the form of a pipe.

Master Roll, that in which are entered the soldiers of every troop, company, regiment, &c.

ROLLS-OFFICE, is an office in Chancery-lane, London, appointed for the custody of the rolls and records in chancery.

ROLLS of parliament, are the manuscript registers, or rolls of the proceedings of our ancient parliaments, which, before the invention of printing, were all engrossed on parchment, and proclaimed openly in every county. In these rolls are also contained a great many decisions of difficult points of law, which were frequently in former times referred to the decision of that high court.

ROLL, or **ROLLER**, is also a piece of wood, iron, brass, &c. of a cylindrical form, used in the construction of several machines. and in several works and manufactures.

ROMAN, in general, something belonging to the city of Rome. See **ROME**.

King of the Romans, in modern history, is a prince elected to be successor to the reigning emperor of Germany.

ROMANCE, in matters of literature, a fabulous relation of certain adventures designed for the entertainment and instruction of the readers.

The true nature and genuine characteristics of this species of writing are excellently explained by the ingenious author of the *Rambler*; who observes, that the works of fiction, with which the present generation seems more particularly delighted, are such as exhibit life in its true state, diversified only by the accidents that daily happen in the world, and influenced by those passions and qualities, which are really to be found in conversing with mankind.

ROMANIA, a province of the pope's territories in Italy, including the Bolognese and Ferrarese. See **Bologna** and **Ferrara**.

ROMANIA, is also the modern name of ancient Thrace, which now makes a province of Turkey in Europe; lying westward of the Propontis, between the Euxine sea and the Archipelago.

ROME, the capital of the pope's territories and of Italy, and anciently the mistress of the Roman Empire: E. lon. 13° N. lat. 41° 45'.

Rome is still a large and fine city, though not to be compared to ancient Rome; the streets are spacious, and magnificently built; it has five bridges over the Tiber, twenty gates, three hundred churches, and a vast number of palaces, convents, triumphal arches, pillars, obelisks, statues, theatres, &c.

ROMNEY, a borough town of Kent, and one of the cinque ports, situated twelve miles south-west of Dover. It sends two members to parliament.

ROMPEE, or **ROMPU**, in heraldry, is applied to ordinaries that are represented as broken, and to chevrons, bends, or the like, whose upper points are cut off. See *Plate CXLVII. fig. 11.*

RONDELETIA, in botany, a genus of the pentandria monogynia class. The corolla is funnel shaped; and the capsule has two cells containing many round coronated seeds. There are two species, none of them natives of Britain.

ROOD, a quantity of land equal to forty square perches, or the fourth part of an acre.

ROOF, in architecture, the uppermost part of a building. See **ARCHITECTURE**, p. 361.

ROOK, in ornithology. See **CORVUS**.

ROOM, a chamber, parlour, or other apartment, in a house. See **ARCHITECTURE**, p. 359.

ROOT, among botanists, denotes that part of a plant which imbibes the nutritious juices of the earth, and transmits them to the other parts. See **AGRICULTURE**, p. 42.

ROOT, in algebra and arithmetic. See **ALGEBRA**, p. 84. &c. and **ARITHMETIC**, p. 420.

ROPE, hemp, hair, &c. spun out into a thick yarn, and then several strings of this yarn twisted together by means of a wheel. When made very small, it is called a cord; and when very thick, a cable.

ROPE-YARN, among sailors, is the yarn of any rope untwisted, but commonly made up of junk; its use is to make sinnet, mats &c.

ROSA, in botany, a genus of the icosaandria polygamia class. The petals are five; the calyx has five fleshy segments; and the seeds are numerous, rough, and inserted into the interior side of the calyx. There are 14 species, five of them natives of Britain, viz. the eglantaria, or sweet briar; the spinosissima, or burnet rose; the arvensis, or white-flowered dogs-rose; the villosa, or apple-rose; and the canina, or red-flowered dogs-rose, or hip-tree.

ROSA-

ROSACEOUS, among botanists, an appellation given to such flowers as are composed of several petals or leaves, disposed in a sort of circular form, like those of the rose.

ROSARY, among the Roman-catholics. See **CHAPLET**.

ROSCOMMON, a county of Ireland, bounded by Letrim on the north, and Galway on the south.

ROSE, in botany. See **ROSA**.

ROSE-NOBLE, an ancient English gold-coin, first struck in the reign of Edward III. It was formerly current at 6s 8d, and so called because stamped with a rose.

ROSMARINUS, in botany, a genus of the diandria monogynia class. The corolla is unequal, and the upper lip of it is split into two segments; the filaments are long, crooked, and simple. There is but one species, viz. the officinalis, a native of Spain.

Rosmary is a very valuable cephalic, and is good in all disorders of the nerves, and in hysterical and hypochondriac diseases. It is good in palsies, apoplexies, epilepsies, and vertigoes.

ROSIENNE, a town of Samogitia, in Poland: E. long. 23° 30'. N. lat. 55° 50'.

ROSIN. See **RESIN**.

ROSS, a county of Scotland, bounded by Sutherland on the north, by the German Sea and the Murray frith on the east and south, and by Inverness-shire and the western ocean on the south and west.

Ross is also a market-town, situated on the river Wye, eleven miles south of Hereford.

ROSSE, a port-town of Ireland, twenty-two miles west of Kinsale.

ROS-SOLIS, SUN-DEW, an agreeable spirituous liquor, composed of burnt brandy, sugar, cinnamon, and milk-water; and sometimes perfumed with a little musk: it is so called, as being at first prepared wholly of the juice of the plant *ros folis*, or drosera. See **DRÖBERA**.

ROSTOCK, an imperial city of Lower Saxony, situated on a bay of the Baltic sea: E. long. 12° 15', and N. lat. 53° 20'.

ROSTOF, or **ROSTOVA**, the capital of a territory of the same name, in Russia: E. lon. 40°, and N. lat. 57° 20'.

ROSTRA, in antiquity, a part of the Roman forum, wherein orations, pleadings, funeral harangues, &c. were delivered.

ROSTRUM, literally denotes the beak or bill of a bird; and hence it has been figuratively applied to the beak, or head of a ship.

ROSYCRUCIANS, **ROSIORUCIANS**, or *brothers of the rosy cross*, a name assumed by a sect or cabal of hermetical philosophers, who appeared, or at least were first taken notice of, in Germany, in the beginning of the XVIIth century. They pretended to be masters of all sciences, and to have many important secrets, particularly that of the philosophers stone.

Their society is frequently denoted by the abbreviatures **F.R.C.**

ROT, a disease incident to sheep, arising from wet seasons, and too moist pasture. It is a very hard thing to prevent the rot, if the year prove very wet, especially in May and June. Salt-marshes, and lands where broom grows, are the best places of preservation for them. Sheep are sometimes all cleared of the rot, when not too far gone

with it, only by removing them into broom-fields. Scurry-grass, mustard, parsley, and thyme, are also good for the prevention of it.

ROTA, the name of an ecclesiastical court at Rome, composed of twelve prelates, whereof one must be a German, another a Frenchman, and two Spaniards; the other eight are Italians, three of whom must be Romans, and the other five a Bolognese, a Ferraran, a Milanese, a Venetian, and a Tuscan.

This is one of the most august tribunals in Rome, which takes cognizance of all suits in the territory of the church, by appeal; as also of all matters beneficiary and patrimonial.

ROTATION, in geometry, a term chiefly applied to the circumvolution of any surface round a fixed and immovable line, which is called the axis of its rotation: and by such rotations it is, that solids are conceived to be generated.

ROTHERAM, a market-town of Yorkshire, 35 miles south-west of York.

ROTHSAY, a parliament-town of Scotland, in the isle of Bute: W. long. 5°, and N. lat. 55° 50'.

ROTONDO, or **ROTONDO**, in architecture, an appellation given to any building that is round both within and without side, whether it be a church, a saloon, or the like. The most celebrated *rotondo* of the ancients, is the pantheon at Rome.

ROTTENNESS. See **PUTREFACTION**.

ROTTERDAM, a city of the province of Holland, situated on the north bank of the Maase, thirty miles south of Amsterdam, and thirteen miles south-east of the Hague: E. long. 4° 20', and N. lat. 52°.

ROTULA, in anatomy. See **ANATOMY**, p. 185.

ROTUNDUS, in anatomy, a name given to several muscles, otherwise called *teres*.

ROUEN, a city of France, and capital of Normandy, situated on the north side of the Seine, sixty-five miles north of Paris, and forty-five miles south-east of Havre de Grace and the British channel: E. long. 1° 6', N. lat. 49° 30'.

ROVIGO, the capital of the Polesin de Rovigo, in Italy, subject to Venice: E. long. 12° 25', N. lat. 45° 6'.

ROUND-HOUSE, a kind of prison, for the nightly watch in London to secure disorderly persons, till they can be carried before a magistrate.

ROUND-HOUSE, in a ship, the uppermost room, or cabin, on the stern of a ship, where the master lies.

ROUNDELAY, a kind of ancient poem thus termed, according to Menage, from its form, because it turns back again to the first verse, and thus goes round. This poem is little known among us, but is very common among the French, who call it *rondeau*. It consists commonly of thirteen verses; eight whereof are in one rhyme, and five in another. It is divided into couplets, at the end of the second and third whereof the beginning of the roundelay is repeated, and that if possible in an equivocal or pausing sense.

ROUSILLON, formerly a province of Spain, now united to France, is bounded by Languedoc on the north, by the Mediterranean sea on the east, by Catalonia on the south, and by the Pyrenean mountains on the west, being about fifty-five miles long, and thirty-six broad.

ROUTE,

ROUTE, a public road, highway, or course, especially that which military forces take. This word is also used for the defeat and flight of an army.

Rout, in law, is applied to an assembly of persons, going forcibly to commit some unlawful act, whether they execute it or not.

ROWEL, among farriers, a kind of issue, made by drawing a skin of silk, thread, hair, or the like, through the nape of the neck, or other part of a horse; answering to what in surgery is called a seton. See **FARRIER**.

ROXBURGH, the name of a county in Scotland, which sends one member to parliament.

ROXENT CAPE, or **Rock of Lisbon**, a mountain and remarkable promontory in Portugal, situated in the Atlantic ocean, at the north entrance of the river Tagus, twenty-two miles north of Lisbon.

ROYAL, something belonging to a king; thus we say, royal family, royal assent, royal exchange, &c.

ROYAL-oak, a fair spreading tree at Boscobel, in the parish of Donnington in Staffordshire, the boughs whereof were once covered with ivy; in the thick of which king Charles II. sat in the day time with colonel Careless, and in the night lodged in Boscobel house: so that they are mistaken who speak of it as an old hollow oak, it being then a gay flourishing tree, surrounded with many more. The poor remains thereof are now fenced in with a handsome wall, with this inscription over the gate in gold-letters: *Felicissimum arborem quam in asylum potentissimi regis Caroli II. Deus op. max. per quem reges regnant, hic crescere voluit, &c.*

ROYAL-society. See **SOCIETY**.

ROYALTIES, the rights of the king, otherwise called the king's prerogative, and the regalia. See **PREROGATIVE**, and **REGALIA**.

ROYENA, in botany, a genus of the decandria digynia class. The calix is uncelated; the corolla consists of one petal, bent back at the edge; the capsule has one cell, and four valves. There are three species, all natives of the Cape of Good Hope.

ROYSTON, a market-town, situated in the counties of Hertford and Cambridge, thirty-eight miles north of London.

RUBELLIO, in ichthyology. See **CYPRINUS**.

RUBETA, in zoology. See **RANA**.

RUBIA, in botany, a genus of the tetrandria monogynia class. The corolla consists of one bell-shaped petal; and the berry contains one seed. There are two species, none of them natives of Britain.

RUBIGALIA, in antiquity, a feast celebrated by the Romans, in honour of the god Rubigus, or the goddess Rubigo, to engage these deities to preserve the corn from blights and mildews.

RUBIGO, a disease incident to corn, commonly called Mildew, being a species of blight. See **BLIGHT**.

RUBININSKA, one of the northern provinces of Russia, bounded by the province of Dwina on the north, by Syriacans on the east, by Belozero on the south, and by the lake of Onega on the west.

RUBRIC, in the canon-law, signifies a title or article in certain ancient law-books; thus called because written, as the titles of the chapters in our ancient Bibles are, in red letters.

RUBUS, in botany, a genus of the icofandria polygynia

class. The calix consists of five segments, and the corolla of five petals; and the berry has many seeds. There are 13 species, five of them natives of Britain, *viz.* theidzeus, or raspberry-bush; the cassus, or small bramble; the fruticosus, or common bramble; the saxatilis, or stone-bramble; and the chamæmorus, or cloud-berry.

RUBY, in natural history, a species of gems, being a beautiful gem of a red colour with an admixture of purple.

This, in its most perfect and best coloured state, is a gem of prodigious beauty and extreme value; it is often found perfectly pure and free from blemishes or foulness, but much more frequently debased greatly in its value by them, especially in the larger specimens. It is of very great hardness, equal to that of the sapphire, and second only to the diamond. It is various in size, but less subject to variations in its shape than most of the other gems. It is usually found very small, its most common size being equal to that of the head of the largest sort of pins; but it is found of four, eight, or ten carats, and sometimes, though very rare, up to twenty, thirty, or forty. It is never found of an angular or crystalliform shape, but always of a pebble-like figure, often roundish, sometimes oblong and much larger at one end than at the other, and in some form resembling a pear, and is usually flattened on one side. It commonly is naturally so bright and pure on the surface, as to need no polishing; and when its figure will admit of being set without cutting, it is often worn in its rough state, and with no other than its native polish.

We have the true ruby only from the East Indies; and the principal mines of it are in the kingdom of Pegu and the island of Ceylon.

RUBY, in heraldry, denotes the red colour wherewith the arms of noblemen are blazoned; being the same which, in the arms of those not noble, is called, gules. See **GULES**.

RUCTATION, a ventosity arising from indigestion, and discharging itself at the mouth with a very disagreeable noise.

RUDBECKIA, in botany, a genus of the syngenesia polygama frutranca class. The receptacle is conical and paleaceous; the pappus has four teeth on its edge; and the calix consists of a double row of scales. There are six species, none of them natives of Britain.

RUDDER, in navigation, a piece of timber turning on hinges in the stern of the ship, and which, opposing sometimes one side in the water and sometimes another, turns or directs the vessel this way or that. See **SHIP**.

RUDENTURE, in architecture, the figure of a rope or staff, sometimes plain, sometimes carved, with which the third part of flutings of columns are frequently filled up.

RUDIARUS, in antiquity, a veteran gladiator who had got a discharge from the service.

RUDIMENTS, the first principles or grounds of any art or science, called also the elements thereof.

RUE, in botany. See **RUTA**.

RUELLIA, in botany, a genus of the didynamia angiospermia class. The calix has five segments, and the corolla is subcampanulated; and the stamina are very near each other. There are eleven species; none of them natives of Britain.

RUFF, in ichthyology. See **PERCA**.

RUFF, in ichthyology. See **TRINGA**.

RUGEN,

RUGEN, an island of the Baltic sea, on the coast of Germany, being part of the duchy of Swedish Pomerania, separated from the continent by a narrow channel: this island is thirty miles long, and near as many broad.

RUINS, a term particularly used for magnificent buildings fallen into decay by length of time, and whereof there only remains a confused heap of materials.

RULE, in matters of literature, a maxim, canon, or precept, to be observed in any art or science.

RULE OF THREE. See **ARITHMETICK**, p. 331.

RULE, or **RULER**, an instrument of wood or metal, with several lines delineated on it, of great use in practical mensuration. When a ruler has the lines of chords, tangents, sines, &c. it is called a plane scale.

RUM, a species of brandy or vinous spirits, distilled from sugar-canes.

Rum, according to Dr. Shaw, differs from simple sugar-spirit, in that it contains more of the natural flavour or essential oil of the sugar-cane; a great deal of raw juice and parts of the cane itself being often fermented in the liquor or solution of which the rum is prepared. The unctuous or oily flavour of rum is often supposed to proceed from the large quantity of fat used in boiling the sugar; which fat, indeed, if coarse, will usually give a sinking flavour to the spirit, in our distillations of the sugar liquor, or wash, from our refining sugar-houses; but this is nothing of kin to the flavour of the rum, which is really the effect of the natural flavour of the cane.

The method of making rum is this: When a sufficient stock of the materials is got together, they add water to them, and ferment them in the common method, though the fermentation is always carried on very slowly at first; because at the beginning of the season for making rum in the islands, they want yeast, or some other ferment to make it work; but by degrees, after this, they procure a sufficient quantity of the ferment, which rises up as a head to the liquor in the operation; and thus they are able afterwards to ferment and make their rum with a great deal of expedition, and in large quantities.

When the wash is fully fermented, or to a due degree of acidity, the distillation is carried on in the common way, and the spirit is made up proof; though sometimes it is reduced to a much greater strength, nearly approaching to that of alcohol or spirit of wine, and it is then called double-distilled rum. It might be easy to rectify the spirit, and bring it to much greater purity than we usually find it to be of: for it brings over in the distillation a very large quantity of the oil; and this is often so disagreeable, that the rum must be suffered to lie by a long time to mellow before it can be used; whereas, if well rectified, it would grow mellow much sooner, and would have a much less potent flavour.

The best state to keep rum in, both for exportation and other uses, is doubtless that of alcohol, or rectified spirit. In this manner it would be transported in one half the bulk it usually is, and might be let down to the common proof-strength with water when necessary: for the common use of making punch, it would likewise serve much better in the state of alcohol; as the taste would be cleaner: and the strength might always be regulated to a much greater exactness than in the ordinary way.

The only use to which it would not so well serve in this state, would be the common practice of adulteration

among our distillers; for when they want to mix a large portion of cheaper spirit with the rum, their business is to have it of the proof-strength, and as full of the flavouring oil as they can, that it may drown the flavour of the spirits they mix with it, and extend its own. If the business of rectifying rum was more nicely managed, it seems a very practicable scheme to throw out so much of the oil, as to have it in the fine light state of a clear spirit, but lightly impregnated with it; in this case it would very nearly resemble arrac, as is proved by the mixing a very small quantity of it with a tasteless spirit, in which case the whole bears a very near resemblance to arrac in flavour.

Rum is usually very much adulterated in England; some are so bare-faced as to do it with malt-spirit; but when it is done with molasses-spirit, the tastes of both are so nearly allied, that it is not easily discovered. The best method of judging of it is, by setting fire to a little of it; and when it has burnt away all the inflammable part, examining the phlegm both by the taste and smell.

RUMELIA, in geography, the same with ancient Greece, now a part of Turkey in Europe.

RUMEN, the paunch, or first stomach of such animals as chew the cud, thence called ruminant animals.

The rumen is by far the largest of all the stomachs, and in it the whole mass of crude aliments, both solid and liquid, lies and macerates, to be thence transmitted to the mouth to be again chewed, comminuted, and fitted for farther digestion in the other ventricles.

RUMEX, in botany, a genus of the hexandria trigynia class. The calix has three leaves, and the corolla three connivent petals; and there is but one triangular seed.

The species are 27, of which ten are natives of Britain.

RUMFORD, a market-town of Essex, ten miles east of London.

RUNGS, in a ship, the same with the floor or ground timbers, being the timbers which constitute her floor, and are bolted to the keel, whose ends are rung-heads.

RUNG-heads, in a ship, are made a little bending, to direct the sweep or mold of the futtocks and navel timbers: for here the lines, which make the compass and bearing of a ship, do begin.

RUNIC, a term applied to the language and letters of the ancient Goths, Danes, and other northern nations.

RUNNER, in the sea-language, a rope belonging to the garnet, and to the two bolt-tackles. It is reeved in a single block joined to the end of a pennant, and has at one end a hook to hitch into any thing, and at the other end a double block, into which is reeved the fall of the tackle, or the garnet, by which means it purchases more than the tackle would without it.

RUNNET, or **RENNET**, the acid juice found in the stomachs of calves that have fed on nothing but milk, and are killed before the digestion is perfect. It curdles milk.

RUPERT'S DROPS, a sort of glass-drops with long and slender tails, which burst to pieces on the breaking off those tails in any part, said to have been invented by prince Rupert, and therefore called after his name. This surprising phenomenon is supposed to arise from hence, that while the glass is in fusion, or in a melted state, the particles of it are in a state of repulsion; but being dropped into cold water, it so condenses the particles in the external parts of their superficies, that they are easily reduced.

duced within the power of each other's attraction, and by that means they form a sort of hard case, which keeps confined the beforementioned particles in their repulsive state; but when this outer-case is broke, by breaking off the tail of the drop, the said confined particles have then a liberty to exert their force, which they do by bursting the body of the drop, and reducing it to a very peculiar form of powder.

RUPERT-FORT, a settlement belonging to the Hudson's Bay company, situated at the bottom of the said bay, in W. long. 80° , N. lat. 51° .

RUPICAPRA, in zoology. See **CAPRA**.

RUPPIA, in botany, a genus of the tetrandria tetragynia class. It has neither calix nor corolla; but four pedicled seeds. There is one species, viz. the marina, or sea-grass.

RUPTURE, in surgery. See **SURGERY**.

RURAL, or **RUSTIC**, in general, denotes something that relates to the country.

RUSCUS, **BUTCHER'S BROOM**, in botany, a plant of the diœcia lyngensia class. The calix of the male consists of six leaves; it has no corolla; the nectarium is central, oval, and perforated at the top: The calix, corolla, and nectarium of the female are the same with those of the male; it has one stylus; and the berry has three cells, and two seeds. There are five species, only one of them, viz. the aculeatus, kaeë-holly, or butcher's-broom, a native of Britain.

RUSH, in botany. See **JUNCUS**.

RUSSIA, or **MUSCOVY**, a large empire, comprehending a vast extent of country, in the most northerly parts of Europe and Asia, from 24° to 130° , E. long. and between 45° and 72° N. lat.

Its capital cities are Moscow and Petersburg.

RUST of a metal, the flower or calx thereof, procured by corroding and dissolving its superficial parts by some menstruum. Water is the great instrument or agent in producing rust; and hence oils, and other fatty bodies, secure metals from rust; water being no menstruum to oil, &c. and therefore not able to make its way through it.

All metals are liable to rust, even gold itself, if exposed to the fumes of sea-salt.

RUSTIC, in architecture, implies a manner of building in imitation of nature, rather than according to the rules of art. See **ARCHITECTURE**.

RUSTIC WORK, is where the stones in the face, &c. of a building, instead of being smooth, are hatched, or picked with the point of a hammer.

RUSTRE, in heraldry, a bearing of a diamond-shape,

pierced through in the middle with a round hole. See **Plate CXLVII.** fig. 12.

RUT, in hunting, the venery or copulation of deer.

RUTA, in botany, a genus of the decandria monogynia class. The calix has five segments; the petals are concave; the germen is surrounded by ten melliferous pores; and the capsule is lobbed. There are three species, none of them natives of Britain.

The dried herb is much used in medicine, by way of infusion; being esteemed an excellent alexipharmic and cephalic, and accordingly prescribed in the small-pox, measles, and hysteric and nervous cases; as also in pneumoniae and pleurifies, to strengthen the stomach, and to prevent the return of habitual colics.

Goat RUE, in botany. See **GALEGA**.

Meadow RUE. See **THALICTRUM**.

Wall RUE. See **ADIANTHUM**.

Book of RUTH, a canonical book of the Old Testament, being a kind of appendix to the book of Judges, and an introduction to those of Samuel; and having its title from the person whose story is here principally related. In this story are observable the ancient rights of kindred and redemption, and the manner of buying the inheritance of the deceased, with other particulars of great note and antiquity.

RUTHYN, a market-town of Denbighshire, eight miles south-east of Denbigh.

RUTICILLA, in ornithology. See **MUSCUAPA**.

RUTILUS, in ichthyology. See **CYPRINUS**.

RUTLAND, the least county in England, bounded by Lincolnshire on the north-east, by Northamptonshire on the south-east, and by Leicestershire on the west and north-west.

RYE, in botany. See **SECALE**.

RYE, in geography, a borough and port town of Suffex, situated on a bay of the English Channel, sixty miles south-east of London. It sends two members to parliament.

RYNCHOPS, in ornithology, a genus belonging to the order of anseres. The beak is straight, the superior mandible being much shorter than the inferior, which is truncated at the point. The species are two, viz. the nigra and fulva, both natives of America.

RYPEN, a city and port-town of Jutland, in Denmark: E. long. 9° N. lat. $55^{\circ} 30'$.

RYSWICK, a fine village in Holland, between the Hague and Delft, where the peace in 1697 was concluded.

RZCEZICA, a city of Lithuania, in Poland, situated on the river Nieper, E. long. 30° , N. lat. 53° .

S.

S. A. B.

SABA, one of the Caribbee islands, subject to the Dutch: W. long. 63° , N. lat. 18° .

SABÆANS, in church-history, a sect of idolaters, much ancients than the Jewish law.

S. A. B.

In the early ages of the world, idolatry was divided between two sects; the worshippers of images, called Sabæans, or Sabians; and the worshippers of fire, called magi. See **MAGI**.

The

The Sabæans began with worshipping the heavenly bodies, which they fancied were animated by inferior deities. In the consecration of their images, they used many incantations to draw down into them from the stars those intelligences for whom they erected them, whose power and influence they held afterwards dwelt in them. This religion, it is said, first began among the Chaldeans, with their knowledge in astronomy; and from this it was, that Abraham separated himself, when he came out of Chaldæa. From the Chaldeans it spread all over the east; and from thence to the Grecians, who propagated it to all the nations of the known world. The remainder of this sect still subsists in the east, and pretend to derive their name from Sabius a son of Seth; and among the books in which the doctrines of this sect are contained, they have one which they call the book of Seth, and which they pretend was written by that patriarch.

SABBATH, or the day of rest, a solemn festival of the Jews, on the seventh day of the week, or Saturday, beginning from sun-set on Friday, to sun-set on Saturday.

The observance of the Sabbath began with the world: for God having employed six days in its creation, appointed the seventh as a day of rest to be observed by man, in commemoration of that great event. On this day the Jews were commanded to abstain from all labour, and to give rest to their cattle. They were not allowed to go out of the city farther than two thousand cubits, or a mile; a custom which was founded on the distance of the ark from the tents of the Israelites, in the wilderness, after their leaving Egypt; for being permitted to go, even on the sabbath day, to the tabernacle to pray, they from thence inferred, that the taking a journey of no greater length, tho' on a different account, could not be a breach of the sabbatical rest.

As the seventh day was a day of rest to the people, so was the seventh year to the land; it being unlawful in this year to plow or sow, and whatever the earth produced belonged to the poor: this was called the sabbatical year. The Jews, therefore, were obliged, during the six years, and more especially the last, to lay up a sufficient store for the sabbatical year.

The modern, as well as the ancient, Jews, were very superstitious in the observance of the sabbath; they carry neither arms, nor gold nor silver about them, and are permitted neither to touch these, nor a candle, nor any thing belonging to the fire; on which account they light up lamps on Friday, which burn till the end of the sabbath.

SABELLIANS, a sect of Christians of the III^d century, that embraced the opinions of Sabellius, a philosopher of Egypt, who openly taught that there is but one person in the Godhead.

The Sabellians maintained, that the Word and the Holy Spirit are only virtues, emanations, or functions of the Deity; and held, that he who is in heaven is the Father of all things, descended into the virgin, became a child, and was born of her as a son; and that having accomplished the mystery of our salvation, he diffused himself on the apostles in tongues of fire, and was then denominated the Holy Ghost. This they explained by resembling God to the sun, the illuminative virtue or quality of which was the Word, and its warming virtue

the Holy Spirit. The Word, they taught, was darted, like a divine ray, to accomplish the work of redemption; and that, being re-ascended to heaven, the influences of the Father were communicated after a like manner to the apostles.

SABINA, in botany. See **JUNIPERUS**.

SABINA, a province of Italy, in the pope's territories, bounded by Umbria on the north, by Naples on the east, by the Campania of Rome on the south, and by St Peter's Patrimony on the west.

SABLE, in zoology. See **MUSTELA**.

SABLE, in heraldry, denotes the colour black, in coats of arms belonging to gentlemen; but in those of noblemen it is called diamond; and in those of sovereign princes, Saturn. See **COLOUR**.

It is expressed in engraving by perpendicular and horizontal hatches crossing one another, as represented in Plate CXLVII. fig. 13.

SABLUSTAN, a province of Persia, which comprehending Gaur and Candahor, is bounded by Choraslan on the north, by India on the east, and by Sigistan on the south.

RABRE, a kind of sword or scimitar, with a very broad and heavy blade, thick at the back, and a little falcated or crooked towards the point: it is the ordinary weapon worn by the Turks, who are said to be very expert in the use of it.

SABURRÆ, **GRITTS**, in natural history, a genus of fossils, found in minute masses, forming together a kind of powder, the several particles of which are of no determinate shape, nor have any tendency to the figure of crystal, but seem rudely broken fragments of larger masses; not to be dissolved or diluted by water, but retaining their figure in it, and not cohering by means of it into a mass; considerably opaque, and in many species fermenting with acids; often fouled with heterogeneous matters, and not unfrequently taken in the coarser stony and mineral or metalline particles.

Gritts are of various colours, as, 1. The stony and sparry gritts, of a bright or greyish white colour. 2. The red stony gritts. 3. The green stony gritts, composed of homogeneous sparry particles. 4. The yellow gritt, of which there is only one species. 5. The black and blackish gritts, composed of stony or talcy particles.

SACCADE, in the manege, is a jerk more or less violent, given by the horseman to the horse, in pulling or twitching the reins of the bridle all on a sudden, and with one pull, and that when a horse lies heavy upon the hand, or obstinately arms himself.

SACCAI, a city and port-town of Japan, situated on the bay of Mecao, three hundred miles south-west of Jeddo: E. long. 135°, and N. lat. 36.

SACCHARUM, in botany, a genus of the triandria digynia class. It has no calix, but long down in place of it; and the corolla has two valves. There are two species, both natives of India. See **SUGAR**.

SACCHARUM SATURNI, *sugar of lead*, is thus ordered to be made in the London Dispensatory; boil cerus, with distilled vinegar, until the vinegar becomes sufficiently sweet; then filter the vinegar through paper, and after due evaporation set it to crystallize.

SACCULUS, in anatomy, a diminutive of *saccus*, signifies a little bag, and is applied to many parts of the body. See **ANATOMY**.

SACER, in ornithology. See **FALCO**.

SACERDOTAL, something belonging to priests. See **PRIEST**.

SACK of wool, a quantity of wool containing just twenty-two stone, and every stone fourteen pounds. In Scotland, a sack is twenty-four stone, each stone containing sixteen pounds.

SACK of cotton wool, a quantity from one hundred and a half to four hundred weight.

SACKS of earth, in fortification, are canvas bags filled with earth. They are used in making retrenchments in haste, to place on parapets, or the head of the breeches, &c. to repair them, when beaten down.

SACKBUT, a musical instrument of the wind kind, being a sort of trumpet, though different from the common trumpet both in form and size: it is fit to play a bass, and is contrived to be drawn out or shortened, according to the tone required, whether grave or acute. The Italians call it *trombone*, and the Latins *tuba ductilis*.

SACRAMENT, signifies, in general, a sign of a thing sacred and holy; and is defined to be an outward and visible sign of a spiritual grace. Thus there are two objects in a sacrament, the one the object of the senses, and the other the object of faith. Protestants admit only of two sacraments, baptism and the eucharist or Lord's supper; but the Roman-catholics own seven, *viz.* baptism, confirmation, the eucharist, penance, extreme unction, ordination, and marriage.

The Romanists, however, by way of eminence, call the eucharist the holy sacrament. Thus to expose the holy sacrament, is to lay the consecrated host on the altar to be adored. The procession of the holy sacrament, is that in which this host is carried about the church, or about a town.

SACRAMENTARY, an ancient Romish church-book, which contains all the prayers and ceremonies practised at the celebration of the sacraments.

It was wrote by pope Gelasius, and afterwards revised, corrected, and abridged by St Gregory.

SACRED, something holy, or that is solemnly offered and consecrated to God, with benedictions, unctions, &c.

SACRIFICE, a solemn act of religious worship, which consisted in dedicating or offering up something animate or inanimate on an altar, by the hands of the priest, either as an expression of their gratitude to the Deity for some signal mercy, or to acknowledge their dependance on him, or to conciliate his favour. The origin of sacrifices is by some ascribed to the Phœnicians: but Porphyry ascribes it to the Egyptians, who first offered the first-fruits of their grounds to the gods, burning them upon an altar of turf: thus in the most ancient sacrifices there were neither living creatures, nor any thing costly or magnificent, and no myrrh or frankincense. At length they began to burn perfumes: and afterwards men leaving their ancient diet of herbs and roots, and beginning to use living creatures for food, they began also to change their sacrifices. The scriptures, however, furnish us with a different account: for Noah, it is said, sacrificed animals at his coming out of the ark; and even Abel himself sacrificed the best and fattest of his flock; but Grotius thinks it more probable that he contented himself with making a mere oblation of his lambs, &c. without slaying them.

The Jews had two sorts of sacrifices, taking the word in its largest signification: The first were offerings of tythes, first-fruits, cakes, wine, oil, honey, and the like; and the last, offerings of slaughtered animals. When an Israelite offered a loaf or a cake, the priest broke it in two parts; and setting aside that half which he reserved for himself, broke the other into crumbs, poured oil, wine, incense, and salt upon it, and spread the whole upon the fire of the altar. If these offerings were accompanied with the sacrifice of an animal, they were thrown upon the victim to be consumed along with it. If the offerings were of the ears of new corn, they were parched at the fire, rubbed in the hand, and then offered to the priest in a vessel, over which he poured oil, incense, wine and salt, and then burnt it upon the altar, having first taken as much of it as of right belonged to himself.

The principal sacrifices among the Hebrews consisted of bullocks, sheep, and goats; but doves and turtles were accepted from those who were not able to bring the other; these beasts were to be perfect, and without blemish. The rites of sacrificing were various, all of which are very minutely described in the books of Moses.

The manner of sacrificing among the Greeks and Romans was as follows. In the choice of the victim, they took care that it was without blemish or imperfection; its tail was not to be too small at the end; the tongue not black, nor the ears cleft; and that the bull was one that had never been yoked. The victim being pitched upon, they gilt his forehead and horns, especially if a bull, heifer, or cow. The head they also adorned with a garland of flowers, a woollen infula or holy fillet, whence hung two rows of chaplets with twisted ribbands; and on the middle of the body a kind of stole pretty large, hung down on each side; the lesser victims were only adorned with garlands and bundles of flowers, together with white tufts or wreaths.

The victims thus prepared were brought before the altar; the lesser being driven to the place, and the greater led by an halter; when if they made any struggle, or refused to go, the resistance was taken for an ill omen, and the sacrifice frequently was set aside. The victim thus brought was carefully examined, to see that there was no defect in it: then the priest, clad in his sacerdotal habit, and accompanied with the sacrificers and other attendants, and being washed and purified according to the ceremonies prescribed, turned to the right-hand and went round the altar, sprinkling it with meal and holy-water, and also besprinkling those who were present. Then the crier proclaimed with a loud voice, Who is here? To which the people replied, Many and good. The priest then having exhorted the people to join with him by saying, Let us pray, confessed his own unworthiness, acknowledging that he had been guilty of divers sins; for which he begged pardon of the gods, hoping that they would be pleased to grant his requests, accept the oblations offered them, and send them all health and happiness; and to this general form added petitions for such particular favours as were then desired. Prayers being ended, the priest took a cup of wine; and having tasted it himself, caused his assistants to do the like; and then poured forth the remainder between the horns of the victim. Then the priest or the crier, or sometimes the most honourable person in the company, killed the beast, by

by knocking it down, or cutting its throat. If the sacrifice was in honour of the celestial gods, the throat was turned up towards heaven : but if they sacrificed to the heroes or infernal gods, the victim was killed with its throat towards the ground. If by accident the beast escaped the stroke, leaped up after it, or expired with pain and difficulty, it was thought to be unacceptable to the gods. The beast being killed, the priest inspected its entrails, and made predictions from them. They then poured wine, together with frankincense, into the fire, to increase the flame, and then laid the sacrifice on the altar ; which in the primitive times was burnt whole to the gods, and thence called an holocaust ; but in after-times, only part of the victim was consumed in the fire, and the remainder reserved for the sacrificers ; the thighs, and sometimes the entrails, being burnt to their honour, the company feasted upon the rest. While the sacrifice was burning, the priest, and the person who gave the sacrifice, jointly prayed, laying their hand upon the altar. Sometimes they played upon musical instruments in the time of the sacrifice, and on some occasions they danced round the altar, singing sacred hymns in honour of the gods.

SACRIFICE, is also a name of an island in the gulph of Mexico, forty-five miles east of *La Vera Cruz* ; it is subject to the Spaniards.

SACRILEGE, the crime of profaning sacred things, or those devoted to the service of God.

SACRISTAN, a church-officer, otherwise called sexton. See **SEXTON**.

SACRISTY, in church history, an apartment in a church, where the sacred utensils were kept ; being the same with our vestry. See **VESTRY**.

SACRO LUMBARIS, in anatomy. See **ANATOMY**, p. 203.

SACRUM OS. See **ANATOMY**, p. 170.

SADERASAPATAN, a possession on the coast of Coromandel forty miles south of Fort St George. Here the Dutch have a factory.

SADDLE, is a seat upon a horse's back, contrived for the convenience of the rider.

A hunting saddle is composed of two bows, two bands, fore-bolsters, pannels, and saddle-traps ; and the great saddle has, besides these parts, corks, hind-bolsters, and a troussiquin.

The pommel is common to both.

SADDUCEES, in Jewish antiquity, a famous sect among the ancient Jews, so called from their founder Sadoc. Antigonus of Socho, president of the sanhedrim at Jerusalem, and teacher of the law in the divinity school of that city. Having often, in his lectures, asserted to his scholars, that they ought not to serve God in a servile manner, with respect to reward, but only out of filial love and fear ; two of his scholars, Sadoc and Bairhus, inferred from thence, that there were no rewards or punishments after this life ; and, therefore, separating from the school of their master, they taught that there was no resurrection, nor future state. Many embracing this opinion, gave rise to the sect of the Sadducees, who were a kind of Epicureans, but differing from them in this, that though they denied a future state, yet they allowed the world was created by the power of God, and governed by his providence ; whereas the followers of Epicurus denied both.

The Sadducees denied all manner of predestination whatever ; and not only rejected all unwritten traditions, but also all the books of the Old Testament, excepting the Pentateuch.

SAFE GUARD, a protection formerly granted to a stranger, who feared violence from some of the king's subjects, for seeking his right by course of law.

SAFFRON, in botany, &c. See **CROCUS**.

Meadow Saffron, in botany. See **COLCHICUM**.

SAGAPENUM, in pharmacy, &c. a gum-resin, brought to us in two forms : the finer and purer is in loose granules, or single drops : the coarser kind is in masses composed of these drops of various sizes, cemented together by a matter of the same kind. In either case, it is of a firm and compact substance, considerably heavy, and of a reddish colour on the outside, brownish within, and spotted in many places with small yellowish or whitish specks. Its smell is strong and disagreeable : its taste acrid and unpleasant.

It is brought to us from Persia and the East-Indies.

Sigapenum is a very great attenuant, aperient, and discutient ; it is good in all disorders of the breast that owe their origin to a tough phlegm.

SAGE, in botany. See **SALVIA**.

SAGENE, a Russian long measure, five hundred of which make a werst : the sagene is equal to seven English feet.

SAGINA, in botany, a genus of the tetrandria tetragynia class. The calix consists of four leaves, and the corolla of four petals ; the capsule has four cells, and four valves, containing many seeds. There are three species, two of them natives of Britain, viz. the procumbens, or pearl-wort ; and the erecta, or the least stitch-wort.

SAGITTA, in astronomy. See **ASTRONOMY**, p. 487.

SAGITTAL SUTURE, in anatomy. See **ANATOMY**, p. 152.

SAGITTARIA, in botany a genus of the monœcia polyandria class. The calix of the male consists of three segments, and the corolla of three petals ; and the stamina are about 24. The calix and corolla of the female are the same with those of the male ; it has no pistillum ; and the seeds are many, and naked. The species are four, only one of them, viz. the sagittifolia, or arrow head a native of Britain.

SAGITTARIUS, in astronomy. See **ASTRONOMY**, p. 487.

SAGO, a simple brought from the East Indies, of considerable use in diet as a restorative.

Sago is a sort of bread produced in the following manner, from a tree called landan, growing in the Molucces. When a tree is felled, they cleave it in two in the middle, and dig out the pith, which is eatable, when it comes fresh out of the tree. They pound it in a mortar, till it is reduced into a kind of powder somewhat like meal. Then they put in a sence made of the bark of the same tree, placing it over a cistern made of its leaves, and pour water on it, which separates the pure part of the powder from the woody fibres wherewith the pith abounds. The flour thus filtrated they call sagu, which they make into paste, and bake it in earthen furnaces.

SAGREE, in ichthyology. See **SQUALUS**.

SAICK, or **SAIQUE**, a Turkish vessel, very common in the Levant for carrying of merchandize.

SAIL, in navigation, an assemblage of several breadths of canvas,

canvas, sewed together by the lifts, and edged round with a cord, fastened to the yards of a ship, to make it drive before the wind. See SHIP.

SAILING, properly denotes the art of navigating and working a ship, or of causing her to observe such motions and directions as are assigned by the navigator; in which sense, sailing differs from navigation, and must be learned by practice on shipboard. See NAVIGATION.

SAINT, in the Romish church, a holy person deceased, and since his decease canonized by the pope, after several informations and ceremonies. See CANONIZATION.

SAINT POIN, in botany. See HEDYSARUM, and AGRICULTURE, p. 65.

SAL, one of the islands of cape Verd, situated in the Atlantic ocean: W. long. 23°, lat. 17°.

SALAMANCA, a city of Spain in the province of Leon, situated on the river Tormes: W. long. 6° 10', N. lat. 41°.

SALAMANDER, in zoology. See LACERTA.

SALAMIS, an island in the gulph of Engia, in European Turkey, situated in E. long. 34°, N. lat. 37° 32', being about fifty miles in circumference.

SALEM, a port-town of New England, a little north of Boston.

SALEP, in the materia medica, the root of a species of orchis. See ORCHIS.

Salep should be chosen clean, firm and hard: it is very little liable either to decay or sophistication. The salep differs very little from the common orchis in virtue. Its appearance is owing to the manner of preparing it, and consequently this may be done from the roots of orchis of our own growth. To prepare these in imitation of salep, Mr. Geoffroy chose the largest, fairest, and plumpest roots he could find: these he nicely skinned; then throwing them into cold water, he suffered them to macerate there for some time: after this he lightly boiled them, and then taking them out of the water and draining them, he had them strung upon threads to be dried in a warm dry air: when the roots were thoroughly dried, they were very transparent, and resembled pieces of tragacanth, and continued dry and hard. The roots thus prepared may be reduced to powder, which will dissolve away in boiling water; and a scruple of it will make a basin full of jelly, in the manner of the Turkish salep. This jelly is an admirable medicine in all cases in which salep is prescribed; and the powder may be given with great success in asses-milk for diseases of the breast.

SALERNO, a city and port-town of Italy, in the kingdom of Naples and the hither principate, situated on a bay of the Tuscan sea: E. long. 15° 20', N. lat. 40° 40'.

SALET, in war, a light covering or armour for the head, anciently worn by the light horse, only differing from the casque in that it had no crest, and was little more than a bare cap.

SALIENT, in fortification, denotes projecting. There are two kinds of angles, the one salient, which are those that present their point outwards; the other re-entering, which have their points inwards. See FORTIFICATION.

SALIENT, SALIENT, or SAILLANT, in heraldry, is applied to a lion, or other beast, when its fore-legs are raised in a leaping posture. See Plate CXLVII. fig. 14.

SALIC, or SALIQUE LAW, an ancient and fundamental law of the kingdom of France, usually supposed to have

been made by Pharamond, or at least by Clovis, in virtue whereof males are only to inherit.

SALICORNIA, in botany, a genus of the monandria monogynia class. The calix is ventricose and entire; it has no corolla, and but one seed. The species are four, only one of them, viz. the europæa, or marsh samfire, a native of Britain.

SALII, in Roman antiquity, priests of Mars, whereof there were twelve, instituted by Numa, wearing painted parti-coloured garments and high bonnets, with a steel-cuirasse on the breast. They were called salii from *saltare*, to dance; because, after assisting at sacrifices, they went dancing about the streets, with bucklers in the left hand, and a rod in the right, striking musically on one another's bucklers with their rods, and singing hymns in honour of the gods.

SALINA, anciently Salamis, a port-town of the island of Cyprus, situated on the south side of the island, in E. long. 34° 30', and N. lat. 34° 30'.

SALINE, a name given to a preparation of sea-salt, procured from the froth of the sea, hardened by the sun in hot countries. It is called by some authors pilatro de Levante, and is used in glass-making; and in the making the fine purple colour from cochineal, by boiling it in a small quantity, with the bran and fœnugreek, of which the magistery is made for that purpose.

SALISBURY, the capital city of Wiltshire, situated eighty miles west of London, and thirty five miles south-east of Bristol. It sends two members to parliament.

SALIVA, SPITTLE, a thin pellucid humour, separated from the arterial blood, by the glands about the mouth and fauces, and conveyed, by proper salival ducts, into the mouth, for several uses. See ANATOMY, p. 307.

SALIVAL, an epithet applied to the glands and ducts which supply and secrete the saliva. See ANATOMY, p. 307.

SALIVATION, in medicine, a promoting of the flux of saliva, by means of medicines, mostly by mercury. The chief use of salivation is in diseases belonging to the glands and the membrana adiposa, and principally in the cure of the venereal disease, though it is sometimes also used in epidemic diseases, cutaneous diseases, &c. whose crises tend that way. See MEDICINE.

SALIX, in botany, a genus of the diccia diandria class. The amentum of both male and female consists of scales; none of them have any corolla; the stylus is bifid; the capsule has but one cell, and two valves; and the seeds are pappous. There are 31 species, 18 of them natives of Britain.

SALÉE, a port-town of the empire of Morrocco, in the kingdom of Fez, situated on the coast of the Atlantic ocean: W. long. 7°, and N. lat. 34°.

SALLY, in the military art, the issuing out of the besieged from their town or fort, and falling upon the besiegers in their works, in order to cut them off, nail their cannon, hinder the progress of their approaches, destroy their works, &c.

SALMO, in ichthyology, a genus belonging to the order of abdominales: The head is smooth, and furnished with teeth, and a tongue; the rays of the gills are from four to ten; the back fin is fat behind; and the belly-fins have many rays. There are 29 species.

SALMON-FISHING. See FISHERY.

SALOON,

SALOON, in architecture, a very lofty spacious hall, vaulted at top, and sometimes comprehending two stories or ranges of windows.

SALONICHI, a city and port-town of Macedonia, in Turkey, anciently called Thessalonica, two hundred and sixty miles west of Constantinople: E. long. 24°, N. lat. 41°.

SALPA, in ichthyology. See **SPARUS**.

SALSETTE, an island on the western coast of the hither India, separated from that of Bombay by a narrow channel: it belongs to the Portuguese, and is twenty miles long, and seventeen broad.

SALSOLA, in botany. See **KALI**.

SALT, the name of a series or subdivision of fossils, naturally and essentially simple, not inflammable, and soluble in water. See **CHEMISTRY**, p. 122, &c.

SALTIER, in heraldry, an ordinary in form of a St. Andrew's cross: which may be said to be composed of a bend dexter and sinister, crossing each other in the centre of the escutcheon. See Plate CXLVII fig. 15.

SALT-PETRE. See **NITRE**.

SALTSBURG, the capital of an archbishopric of the same name, in Bavaria, situated on the river Salza, seventy miles east of Munich: E. long. 13°, N. lat. 47° 45'.

SALVADORA, in botany, a genus of the tetrandria monogynia class. The calix has four segments; it has no corolla; the berry contains but one seed, furnished with an awn. There is one species, a native of India.

SALVAGE MONEY, a reward allowed by the civil and statute law, for the saving of ships or goods from the danger of the seas, pirates, or enemies.

Where any ship is in danger of being stranded, or driven on shore, justices of the peace are to command the constables to assemble as many persons as are necessary to preserve it; and on its being preserved by their means, the persons assisting therein shall in thirty days after be paid a reasonable reward for their salvage, otherwise the ship or goods shall remain in the custody of the officers of the customs as a security for the same.

SALVIA, in botany, a genus of the diandria monogynia class. The corolla is unequal; and the filaments fixed transversely to a pedicle. There are 32 species, two of them natives of Britain, *viz.* the pratensis, or meadow-clary; and the verbera, or wild-clary.

SALUTATION, the act of saluting, greeting, or paying respect and reverence to any one.

There is a great variety in the forms of salutation. The orientals salute by uncovering their feet, laying their hands on their breasts, &c. In Britain, we salute by uncovering the head, bending the body, &c. The pope makes no reverence to any mortal, except the emperor, to whom he stoops a very little, when he permits him to kiss his lips.

SALUZZO, a city of Italy, the capital of a marquise of the same name in Piedmont, seventeen miles south of Turin.

SAMARCAND, a city of Usbec Tartary, formerly its capital: E. long. 66°, N. lat. 40°.

SAMARIA, an ancient city of Palestine, in Asiatic Turkey, forty-five miles north of Jerusalem.

SAMARITANS, an ancient sect among the Jews, still subsisting in some parts of the Levant, under the same name.

Its origin was in the time of Rehoboam, under whose

reign the people of Israel were divided into two distinct kingdoms, that of Judah and that of Israel; when the capital of the latter being Samaria, the Israelites obtained the name of Samaritans.

They were anciently guilty of idolatry, and the rabbins pretend, that they worshipped the figure of a dove on mount Gerizim; but the present Samaritans, who are but few in number, are far from being idolaters. They celebrate the passover every year, on the fourteenth day of the first month, on mount Gerizim, and begin that feast with the sacrifice appointed for that purpose in Exodus: they keep the sabbath with all the rigour with which it is enjoined in the book of Exodus, none among them stirring out of doors but to the synagogue: they sacrifice nowhere but on mount Gerizim: they observe the feasts of expiation, tabernacles, harvest, &c. and never defer circumcision beyond the eighth day; they never marry their nieces, as the Jews do; have but one wife; and in fine, do nothing but what is commanded in the law.

SAMBALLAS, or **SAMBLAS ISLANDS**, several islands situated in the American ocean, near the coast of Darien, none of which are inhabited: E. long. 81°, N. lat. 40°.

SAMBUCUS, in botany, a genus of the pentandria trigynia class. The calix and corolla consist of five segments; and the berry contains three seeds. There are four species, two of them natives of Britain, *viz.* the nigra, or common elder; and the ebulus, or dwarf elder.

The inner green bark of this shrub is gently cathartic. **SAMIAN EARTH**, in the materia medica, the name of two species of marble used in medicine, *viz.* 1. The white kind, called by the ancients collyrium samium; being astrigent, and therefore good in diarrhæas dysenteries, and hæmorrhages; they also used it externally in inflammations of all kinds. 2. The brownish-white kind, called after samius, by Dioscorides: this also stands recommended as an astringent.

SAMOGITIA, a maritime province of Poland, bounded by Courland on the north, and by the Baltic on the west.

SAMOIDA, the most northerly province of Russia in Europe, situated on the frozen ocean, and the river Oby.

SAMOLUS, in botany, a genus of the pentandria monogynia class. The corolla is rotated; the stamina are fortified by scales; and the capsule has one cell. There is but one species, *viz.* the valerandi, or round-leaved water pimpernel, a native of Britain.

SAMOS, a fertile island of the Archipelago, thirty miles south of Smyrna: E. long. 27° 30', N. lat. 37° 30'.

SAMOTHRACIA, a small island in the Egean sea, near the coast of Thrace.

SAMPSEANS, in church-history, an ancient sect, who were properly neither Jews, Christians, nor Gentiles, though they took their name from the Hebrew word *se-mes*, sun; as though they worshipped that planet.

They acknowledged only one God; wash'd themselves often; and in almost every thing attached themselves to the religion of the Jews.

Books of SAMUEL, two canonical books of the Old Testament, so called as being usually ascribed to the prophet Samuel.

The books of Samuel, and the books of Kings, are a continued history of the reigns of the Kings of Israel and Judah; for which reason the books of Samuel are like-

wife styled the first and second books of Kings. Since the first twenty-four chapters contain all that relates to the history of Samuel, and the latter part of the first book, and all the second, include the relation of events that happened after the death of that prophet, it has been supposed that Samuel was author only of the first twenty-four chapters, and that the prophets Gad and Nathan finished the work. The first book of Samuel comprehends the transactions under the government of Eli, and Samuel; and under Saul, the first king; and also the acts of David, whilst he lived under Saul; and is supposed to include the space of a hundred and one years. The second book contains the history of about forty years, and is wholly spent in relating the transactions of king David's reign.

SAMYDA, in botany, a genus of the decandria monogynia class. The calyx consists of five coloured leaves; it has no corolla; and the berry has three valves, and one cell. There are five species, none of them natives of Britain.

SANCTIFICATION, the act of sanctifying, or rendering a thing holy.

The reformed divines define sanctification to be an act of God's grace, by which a person's desires and affections are alienated from the world, and by which he is made to die to sin, and to live to righteousness; or, in other words, to feel an abhorrence of all vice, and a love of virtue and religion.

SANCTION, the authority given to a judicial act, by which it becomes legal and authentic.

SANCTUARY, among the Jews, also called *Sanctum sanctorum*, or Holy of holies, was the holiest and most retired part of the temple of Jerusalem, in which the ark of the covenant was preserved, and into which none but the high priest was allowed to enter, and that only once a year, to intercede for the people. Some distinguish the sanctuary from the *sanctum sanctorum*, and maintain that the whole temple was called the sanctuary.

To try and examine any thing by the weight of the sanctuary, is to examine it by a just and equal scale: because, among the Jews, it was the custom of the priests to keep stone weights, to serve as standards for regulating all weights by, though these were not at all different from the royal, or profane weights.

Sanctuary, in the Romish church, is also used for that part of the church in which the altar is placed, encompassed with a rail or balustrade.

SANCTUARY, in our ancient customs, is the same as a sylum. See **ASYLUM**.

SAND, in natural history, a genus of fossils, the characters of which are, that they are found in minute concretions; forming together a kind of powder, the genuine particles of which are all of a tendency to one determinate shape, and appear regular, though more or less complex concretions; not to be dissolved or disunited by water, or formed into a coherent mass by means of it, but retaining their figure in it; transparent, vitrifiable by extreme heat, and not dissoluble in, nor effervescing with, acids. Sands are subject to be variously blended both with homogeneous and heterogeneous substances, as that of talcs, &c. and hence, as well as from their various colours, are subdivided into a number of species.

SAND-BAGS, in the art of war, are bags filled with earth or sand, holding each about a cubic foot: their use is to

raise parapets in haste, or to repair what is beaten down.

SANDECK, a town of little Poland, thirty-five miles south-east of Cracow.

SANDEEL, *ammodytes*, in ichthyology. See **AMMODYTES**.

SANDAL, in antiquity, a rich kind of slipper worn on the feet by the Greek and Roman ladies, made of gold, silk, or other precious stuff, consisting of a sole, with a hollow at one extreme to embrace the ankle, but leaving the upper part of the foot bare.

Sandal, is also used for a shoe or slipper worn by the pope, and other Romish prelates, when they officiate. It is also the name of a sort of slipper worn by several congregations of reformed monks. This last consists of no more than a mere leathern sole, fastened with latches or buckles, all the rest of the foot being left bare. The capuchins wear sandals; the recolects, clogs: the former are of leather, and the latter of wood.

SANDARACH, in natural history, a very beautiful native fossil, though too often confounded with the common facitious red arsenic, and with the red matter formed by melting the common yellow orpiment.

It is a pure substance, of a very even and regular structure, is throughout of that colour which our dyers term an orange-scarlet, and is considerably transparent even in the thickest pieces. But though, with respect to colour, it has the advantage of cinnabar while in the mass, it is vastly inferior to it when both are reduced to powders. It is moderately hard, and remarkably heavy, and, when exposed to a moderate heat, melts and flows like oil: if set on fire, it burns very briskly.

It is found in Saxony and Bohemia, in the copper and silver mines; and is sold to the painters, who find it a very fine and valuable red: but its virtues or qualities in medicine, are no more ascertained at this time, than those of the yellow orpiment.

Gum-SANDARACH, is a dry and hard resin, usually met with in loose granules, of the bigness of a pea, a horse bean, or larger; of a pale whitish yellow, transparent, and of a resinous smell, brittle, very inflammable, of an acrid and aromatic taste, and diffusing a very pleasant smell when burning. It is produced from a species of the juniper.

It flows only from these trees in hot countries; but the natives promote its discharge by making incisions in the bark.

Sandarach is good in diarrhoeas, and in hæmorrhages. The varnish-makers make a kind of varnish of it by dissolving it in oil of turpentine or linseed, or in spirit of wine.

SANDIVER, a whitish salt, continually cast up from the metal, as it is called, whereof glass is made; and, swimming on its surface, is skimmed off.

Sandiver is also plentifully thrown out in the eruptions of volcanoes; some is of a fine white, and others tinged bluish or yellowish.

Sandiver is detergent, and good for foulnesses of the skin. It is also used by gilders of iron.

SANDIX, a kind of minium, or red-lead, made of ceruse, but much inferior to the true minium.

SANDWICH, one of the cinque-ports, in Kent, ten miles east of Canterbury: it sends two members to parliament, and gives the title of Earl to the noble family of Montague.

SANGUI-

SANGUIFICATION, in the animal œconomy, the conversion of chyle into true blood. See **CHYLE**.

SANGUINARIA, blood-wort, in botany, a genus of the polyandria monogynia class. The corolla consists of eight petals, and the calix of two leaves; the pod is oval, with one cell. There is but one species, a native of America.

SANGUINE, in general, something abounding with, or resembling blood. See **BLOOD**.

SANGUIS. See **BLOOD**.

SANGUISORBA, in botany, a genus of the tetrandria monogynia class. The calix has two leaves; and the germs are situate between the calix and corolla. There are three species, only one of them, *viz.* the officinalis, or burnet, a native of Britain, the leaves of which are mildly astringent.

SANHEDRIM, among the Jews, the great council of the nation, consisting of seventy senators, taken partly from among the priests and levites, and partly out of the inferior judges, who formed what was called the lesser sanhedrim. The room they met in was a rotunda, half of which was built without the temple, and half within. The nasi, or president of the sanhedrim, sat upon a throne, with his deputy on his right hand, his sub-deputy on his left, and the other senators ranged in order on each side.

The authority of this council was very extensive: for they decided such causes as were brought before them by way of appeal from the inferior courts; and the king, the high-priests, and prophets, were under the jurisdiction of this tribunal. They had the right of judging in capital cases, and sentence of death might not be pronounced in any other place; for which reason the Jews were forced to quit this hall, when the power of life and death was taken out of their hands, forty years before the destruction of the temple, and three years before the death of Christ.

There were several inferior sanhedrims in Palestine, each of which consisted of twenty-three persons; all these depended on the great sanhedrim of Jerusalem.

SANICULA, in botany, a genus of the pentandria digynia class. The umbellæ are thick; the fruit is rough; and the flowers of the disk are abortive. The species are three, only one of them, *viz.* the europæa, or fanicle, is a native of Britain. The leaves are supposed to be vulnerary.

SANIDIUM, in natural history, the name of a genus of fossils, of the class of the selenitæ, but neither of the rhomboidal nor columnar kinds, nor any other way distinguishable by its external figure, being made up of several plain flat plates.

SANIES in medicine, a ferous putrid matter, issuing from wounds; it differs from pus, which is thicker and whiter.

SANQUHAR, a borough-town of Scotland, in the county of Nithsdale, twenty-one miles north of Dumfries.

SANTA CLARA, an island in the Pacific Ocean, situated in the bay of Guayaquil: W. long. 80°, S. lat. 3° 15'.

SANTA CRUZ, a port town on the north side of the island of Cuba, in North America: W. long. 85° 30', N. lat. 22° 30'.

SANTA FE, the capital of New Mexico: W. long. 109°, N. lat. 36°.

SANTA FE DE BAGO, the capital of Terra Firma, in South America: W. long. 74°, N. lat. 4° 30'.

SANTA MARIA, a town of Terra Firma, in the province of Darien, situated on a river of the same name, a little east of the bay of Panama: W. long. 80°, N. lat. 7° 40'.

SANTALUM, in botany, a genus of the octandria monogynia class. The corolla consists of one petal; the stamina lie upon the tube; and the stigma is simple; and the fruit is a berry. There is but one species, a native of India. The wood is reckoned to be attenuant and cordial.

SANTILLANA, a city and port-town of Spain, the capital of the eastern Asturias, situated on the bay of Biscay: W. long. 5°, and N. lat. 43° 35'.

SANIGOLINA, a genus of the syngenesia polygamia æqualis class. The receptacle is paleaceous; the pappus is very short; and the calix is hemispherical and imbricated. The species are four, none of them natives of Britain.

SANTORINI, an island of the Archipelago, thirty-five miles in circumference: E. long. 25° 35', N. lat. 36° 10'.

SAONE, a river of France, which rises in Lorrain, and falls into the Rhone at Lyons.

SAP, a juice furnished by the earth, and changed into the plant. See **AGRICULTURE**, p. 45.

SAPHENA, in anatomy. See **ANATOMY**, p. 243.

SAPIENZA, an island and cape in the mediterranean sea, on the south-west point of the Morea, E. long. 21° 15', N. lat. 36° 45'.

SAPPIC, in poetry, a kind of verse much used by the Greeks and Latins, denominated from the inventress Sappho. The Sapphic verse consists of five feet, whereof the first, fourth, and fifth are trochees, the second a spondee, and the third a dactyl.

SAPINDUS, in botany, a genus of the octandria digynia class. The calix consists of four leaves; and the corolla of four petals; and there are three round, connate, ventricose capsules. The species are three, none of them natives of Britain.

SAPO. See **SOAP**.

SAPONARIA, in botany, a genus of the decandria digynia class. The calix consists of one leaf, and the corolla of five clawed petals; and the capsule is oblong, with one cell. There are six species, only one of them, *viz.* the officinalis, or soap-wort, a native of Britain. The root of this species is supposed to be aperient, corroborant, and sudorific.

SAPPHIRE, a pellucid gem, which, in its finest state, is extremely beautiful and valuable, and second only to the diamond in lustre, hardness, and price. Its proper colour is a pure blue; in the finest specimens it is of the deepest azure, and in others varies into palefens in shades of all degrees, between that and a pure crystal brightness and water, without the least tinge of colour, but with a lustre much superior to the crystal. They are distinguished into four sorts, *viz.* the blue sapphire, the white sapphire, the water sapphire, and the milk sapphire.

The gem known to us by this name is extremely different from the sapphire of the ancients, which was only a semi-opaque stone, of a deep blue, veined with white, and spotted with small gold-coloured spangles, in the form of stars, and was only a more beautiful kind of the lapis lazuli: but our sapphire they have described under the name of beryllus aeroides, or the sky blue beryl.

The finest sapphires in the world are brought from the kingdom

kingdom of Pegu in the East Indies, where some are found perfectly colourless, and others of all the shades of blue; these are all found in the pebble form. We have very fine sapphires also, partly pebble, partly crystal-shaped, from Bishnagar. Conanor, Calicut, and the island of Ceylon: these also are of all the shades of blue. And in Ceylon there are sometimes found a sort of bastard gems, of a mixed nature between the sapphire and ruby. The occidental are from Silesia, Bohemia, and many other parts of Europe; but though these are often very beautiful stones, they are greatly inferior, both in lustre and hardness, to the oriental.

SAPPHIRINE WATER, in the materia medica, also called blue eye-water, is thus prepared: Pour a pint of lime-water, made strong and fresh, into a copper-vessel, add to it a dram of crude sal armoniac, and throw in some filings or small pieces of copper, and let it stand till it has acquired a beautiful colour.

This is used as an eye-water; as also to deterge old ulcers: and sometimes it is mixed with other things in injections in gonorrhoeas.

SARABAITES, a sort of monks among the ancient christians, who did not resort to the wilderness as others did, but lived publicly in cities. Two or three of them usually dwelt together, but they had no rule or government; they however observed very strict fasts; wore loose sleeves, wide stockings, coarse clothes, frequently sighted, and always bitterly inveighed against the clergy.

SARABAND, a musical composition in triple time, the motions of which are slow and serious.

SARACENS, the inhabitants of Arabia; so called from the word *sara*, which signifies a desert, as the greatest part of Arabia is: and this being the country of Mahomet, his disciples were called Saracens.

SARAGOSSA, the capital of the province of Arragon in Spain: W. long. $1^{\circ} 15'$, and N. lat. $41^{\circ} 32'$.

SARCASM, in rhetoric, a keen bitter expression which has the true point of satire, by which the orator scoffs and insults his enemy: such was that of the Jews to our Saviour, "He saved others, himself he cannot save."

SARCOCELE, in surgery, a spurious rupture, or hernia, wherein the testicle is considerably tumified or indurated, like a scirrhus, or much enlarged by a fleshy excrescence, which is frequently attended with acute pains, and sometimes ulceration; so as to degenerate at last into a cancerous disposition. See **SURGERY**.

SARCOCOLLA, in pharmacy, a gum-resin, which approaches greatly to the nature of the simple gums.

It is brought to us from Persia and Arabia, in small granules moderately heavy, and of a whitish, brownish, or reddish colour, very friable, of a faintish disagreeable smell, and of an acrid and nauseous taste.

Hoffman absolutely condemns the internal use of it. However, it is recommended in ophthalmias, and deflections of a sharp matter upon the eyes; and is generally ordered to be dissolved in milk for this purpose.

SARCOLOGY is that part of anatomy which treats of the soft parts, viz. the muscles, intestines, arteries, veins, nerves, and fat. See **ANATOMY**.

SARCOMA, in surgery, denotes any fleshy excrescence.

SARCOPHAGOUS MEDICINES, in surgery, &c. are those which eat away proud flesh, and otherwise called caustics. See **CAUSTICS**.

SARCOTICS, in surgery, medicines which generate flesh in wounds.

SARDINIA, an island of the Mediterranean, situated between 8° and 10° E. long. and between 39° and 41° N. lat. It is about one hundred and forty miles long, and sixty broad; and gives the title of king to the duke of Savoy, under whose dominion it is.

SARDIS, the ancient capital of Lydia, in Asia, now in ruins.

SARDONYX, in natural history, a genus of semi-pellucid gems, of the onyx structure, zoned or tabulated, and composed of the matter of the onyx variegated with that of the red or yellow carnelian. See **CARNELIAN** and **ONYX**.

SARGUS, in ichthyology. See **SPARUS**.

SARK, a little island between Guernsey and Jersey, subject to Great Britain.

SAROTHTA, in botany, a genus of the pentandria trigynia class. The calix consists of five segments, and the corolla of five petals; the capsule is coloured, and has three cells and one valve. There is but one species, a native of Virginia.

SARSAPARILLA, in botany. See **SMILAX**.

SARTORIUS, in anatomy. See **ANATOMY**, p. 207.

SARUM, or **OLD SARUM**, a borough-town of Wiltshire, situated a little north of Salisbury. It sends two members to parliament.

SASSAFRAS, in botany. See **LAURUS**.

The wood is imported in large straight blocks: it is said to be warm, aperient, and corroborant; and frequently employed, with good success, for purifying and sweetening the blood and juices; for which purpose an infusion, in the way of tea, is a very pleasant drink: its oil is very fragrant, and possesses most of the virtues of the wood.

SATELLITE in astronomy, the same with a secondary planet, or moon. See **ASTRONOMY**.

SATRAPA or **SATRAPES**, in Persian antiquity, denotes an admiral; but more commonly the governor of a province.

SATTIN, a glossy kind of silk stuff, the warp of which is very fine, and stands out so as to cover the coarser woof.

SATTINET, a slight thin kind of sattin, commonly striped, and chiefly used by the ladies for summer night-gowns.

SATURANTS, in pharmacy. See **ABSORBENTS**.

SATURATION, in chemistry, is the impregnating an acid with an alkali, or *vice versa*, till either will receive no more, and the mixture will become neutral.

SATURDAY the seventh or last day of the week, so called from the idol Seater, worshipped on this day by the ancient Saxons, and thought to be the same as the Saturn of the Latins.

SATUREIA, in botany, a genus of the didynamia gymnospermia class. The lacinae of the corolla are nearly equal; and the stamina are approximate. The species are nine, none of them natives of Britain.

The leaves of summer savory are very pungent, warm, and aromatic; and afford, in distillation with water, a subtle essential oil. Both are esteemed good in crudities of the stomach, asthma, and menstrual obstructions.

SATURN, in astronomy. See **ASTRONOMY**, p. 442.

SATURN,

SATURN, in chemistry, &c. an appellation given to lead.

See *CHEMISTRY*, p. 84, 136

SATURN, in heraldry, denotes the black colour, in blazoning the arms of sovereign princes.

SATURNALIA, in Roman antiquity, a festival observed about the middle of December, in honour of the god Saturn, whom Lucan introduces giving an account of the ceremonies observed on this occasion thus: "During my whole reign, which lasts but for one week, no public business is done; there is nothing but drinking, singing, playing, creating imaginary kings, placing servants with their masters at table, &c. There shall be no disputes, reproaches &c. but the rich and poor, masters and slaves, shall be equal." &c.

On this festival the Romans sacrificed bare-headed, contrary to their custom at other sacrifices.

SATURNINE, an appellation given to persons of a melancholy disposition, as being supposed under the influence of the planet Saturn.

SATYRE, in the heathen mythology, a fabulous kind of demi-god, or rural deity, of the ancient Romans, represented with goat's feet, and sharp pricked up ears.

SATYR, or **SATIRE**, in matters of literature, a discourse or poem, exposing the vices and follies of mankind.

The chief satyrists among the ancients are Horace, Juvenal, and Persius; those among the moderns, Regnier, and Boileau, in French; and Dryden, Oldham, Rochester, Buckingham, Pope, Young, &c. among the English.

SATYRIUM, a genus of the gynandria diandria class. The nectarium resembles a scrotum, placed behind the flower. The species are eight, 4 of them natives of Britain.

SAVANNA, a town and river of Georgia, in North-America: W. long. 81° 20', N. lat. 32°.

SAUCISSE, or **SAUSAGE**, in the military art, a long train of powder, sewed up in a roll of pitched cloth, about two inches in diameter, serving to fire fire to mines.

SAUCISSON, in fortification, a mass of large branches of trees bound together; and differing only from a fascine, as this is composed of small branches of twigs.

Saucissons are employed to cover the men, and to make epaulements

SAVE, a large river of Germany which rising in Carinthia, runs east through Carniola and Croatia, and dividing Sclavonia from Turkey, discharges itself into the Danube at Belgrade.

SAVIN, in botany. See *JUNIPERUS*.

SAVIOUR, an appellation peculiarly given to Jesus Christ, as being the true Messiah, and Saviour of the world.

Order of St SAVIOUR, a religious order in the Romish church, founded by St Bridget, about the year 1345; and so called from its being pretended that our Saviour himself dictated to the foundress its constitutions and rules.

According to the constitutions, this order is principally founded for religious women who pay a particular honour to the holy virgin: but there are some monks of the order, to administer the sacraments, and spiritual assistance to the nuns.

SAUMUR, a city of France, in the province of Orleans, and duchy of Anjou; twenty-four miles east of Anjou.

SAUNDERS. See *SANTALUM*.

SAVOLAXIA, a subdivision of Finland, in Russia, situated between Cajania, Kexholm, Carelia, and Bothnia.

SAVORY, in botany. See *SATUREIA*.

SAVOUR. See *TASTE*.

SAVOY, a duchy, situated between France and Italy, on the west side of the Alps; bounded by the lake and territory of Geneva, on the north; by Switzerland and Piedmont, on the east; by another part of Piedmont and Dauphine, on the south; and by Franche Compté and Dauphine, on the west.

SAUVAGESIA, in botany, a genus of the pentandria monogynia class. The calix consists of five leaves, and the corolla of five fimbriated petals; the nectarium has five leaves, lying alternately between the petals; and the capsule has one cell. There is but one species, a native of Jamaica

SAW, an instrument which serves to cut into pieces several solid matters; as wood, stone, ivory, &c.

The best saws are of tempered steel ground bright and smooth: those of iron are only hammer hardened; hence, the first, besides their being stiffer, are likewise found smoother than the last. They are known to be well hammered by the stiff bending of the blade; and to be well and evenly ground, by their bending equally in a bow.

SAW-FISH. See *SGUALUS*.

SAXIFRAGA, in botany, a genus of the decandria digynia class. The calix consists of five segments, and the corolla of five petals; the capsule has a double beak and one cell. The species are 38, nine of them natives of Britain

The tuberosities at the root of the granulata or white-flowered saxifrage are kept in the shops, under the name of saxifrage-seeds; they are diuretic and attenuant; and therefore good in nephritic cases and obstructions of the menfes and viscera.

SAXONY, the name of two circles of the German empire, distinguished by the epithets Upper and Lower. The circle of Upper Saxony comprehends the duchy of Saxony, the marquissates of Misnia, Lusatia, and Brandenburg, and the duchies of Pomerania, Sax Hall, Sax Altemburg, Sax Merzburg, and Sax Naumburg. The circle of Lower Saxony comprehends the duchies of Mecklenburg, Holstein, Lawenburg, Lunenburg, Zell, Bremen, Brunswic, Hanover, and Magdeburg; the principalities of Verden and Halberstadt, and the bishoprick of Hildesheim.

SAY, or **SAVE**, in commerce, a kind of serge or woollen stuff, much used abroad for linings, and by the religious for shirts: with us it is used for aprons by several sorts of artificers, being usually dyed green.

SCABIOSA, in botany, a plant of the tetrandria monogynia class. The common calix consists of many leaves, and the proper one is double; the receptacle is paleaceous. The species are 25, three of them natives of Britain, viz. the succisa, or devil's bit; the arvensis, or common field scabious; and the columbaria, or lesser field scabious.

SCAFFOLD, among builders, an assemblage of planks and boards sustained by tressels and pieces of wood fixed in the wall; whereon masons, brick-layers, &c. stand to work in building high walls, &c. and plasterers in plastering ceilings, &c.

Scaffold also denotes a timber-work raised in the manner of an amphitheatre, for the more commodious viewing any shew or ceremony: it is also used for a little stage, raised in some public place, whereon to behold criminals.

SCAGEN, a promontory of North Jutland, at the entrance of the Scagerrac sea, or passage out of the ocean into the Baltic sea: E. lon. 10° , N. lat. 58° .

SCALADO, or SCALADE, in the art of war, a furious assault made on the wall or rampart of a city, or other fortified place, by means of ladders, without carrying on works in form to secure the men.

SCALE, a mathematical instrument, consisting of several lines drawn on wood, brass, silver, &c. and variously divided, according to the purposes it is intended to serve; whence it acquires various denominations, as the plain scale, diagonal scale, plotting scale. See GEOMETRY.

SCALE, in music, is a denomination given to the arrangement of the six syllables invented by Guido Aretine, *ut, re, mi, fa, sol, la*, called also gammut. See MUSIC.

SCALENE, or SCALENOUS TRIANGLE, *scalenum*, in geometry, a triangle whose sides and angles are unequal. See GEOMETRY.

SCALENUS, in anatomy. See ANATOMY, p. 214.

SCALPEL, in surgery, a kind of knife used in anatomical dissections and operations in surgery.

SCALPER, or SCALPING-IRON, a surgeon's instrument used for scraping foul carious bones.

SCALPRA DENTALIA, instruments used by the surgeons to take off those black, livid, or yellow crusts, which infest the teeth, and not only loosen and destroy them, but taint the breath.

SCAMMONY, a concreted vegetable juice of a species of convolvulus, partly of the resin, and partly of the gum-kind.

The Aleppo scammony is of a spongy texture, light and friable: it is of a faint disagreeable smell, and its taste is bitterish, very nauseous, and acrimonious. The Symrna scammony is considerably hard and heavy, of a black colour, of a much stronger smell and taste than the former, otherwise it much resembles it.

Scammony is in great esteem and frequent use. It is an ingredient in many compositions of the shops; and these are prescribed, with other cathartics, for purging off ferous humours. It is in general, however, a better purge for robust people than for those of more delicate constitutions; though, with the correctives with which it is joined, it is given with safety and success to children.

SCANDALUM MAGNATUM, in law, is a defamatory speech or writing to the injury of a person of dignity; for which a writ that bears the same name is granted for the recovery of damages.

SCANDeroon, a port-town of Aleppo, in Asiatic Turkey, situated on the coast of the Lesser Asia: E. long. 36° , N. lat. $37^{\circ} 15'$.

SCANDINAVIA, a large country which consisted of Sweden, Denmark, and Norway, which were sometimes under the government of one prince; but is now under the dominion of Sweden and Denmark.

SCANDIX, in botany, a genus of the pentandria digynia class. The corolla is of an irregular shape; the fruit is subuloid; the petals are entire; and the stamules of the

disc are generally males. There are eight species, two of them natives of Britain, *viz.* the peckin, shepherds' needle, or venus's comb; and the onthrificus, or small hemlock stervill.

SCANNING, in poetry, the measuring of a verse by feet, in order to see whether or no the quantities be duly observed.

The term is chiefly used in regard to the Greek and Latin verses. Thus an hexameter verse is scanned, by resolving it into six feet; a pentameter, by resolving it into five feet, &c.

SCAPE-GOAT, in Jewish antiquity, the goat which was set at liberty on the great day of expiation.

Spencer is of opinion, that the scape-goat was called Azazel, because it was sent to Azazel, *i. e.* the devil; the reasons of which ceremony, he takes to be these: 1. That the goat, loaded with the sins of the people, and sent to Azazel, might denote the miserable condition of the sinners. 2. The goat was sent thus loaded to the demons, to shew that they were impure, and to deter the people from worshipping them. 3. That the goat sent to Azazel sufficiently expiating the sins of the Israelites, they might the more willingly abtain from the expiatory sacrifices of the heathens.

SCAPHOIDES, or os naviculare. See ANATOMY, p. 186.

SCAPULA, in anatomy. See ANATOMY, p. 176.

SCAPULAR, in anatomy, a name given to two pair of arteries and as many veins. See ANATOMY, Part III. and IV.

SCAPULAR, or SCAPULARY, a part of the habit of several religious orders in the church of Rome, worn over the gown, as a badge of peculiar veneration for the blessed Virgin. It consists of two narrow breadths or slips of cloth, covering the back and the breast, and hanging down to the feet.

The devotees of the scapulary celebrate its festival on the 16th of July.

SCARABÆUS, the BEETLE, in zoology, a genus of insects, of the coleoptera order: the antennæ of the beetles are of a clavated figure, and fissile longitudinally, and their legs are frequently dentated. There are 87 species.

SCARBOROUGH, a borough and port town of Yorkshire, thirty-seven miles north-east of York.

It sends two members to parliament, and is famous for a medicinal spring, which has been the subject of great contentions and disputes among the physical people; all allowing it considerable virtues, but some attributing them to one ingredient, others to another.

SCARIFICATION, in surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping instrument. See SURGERY.

SCARLET, a beautiful bright red colour.

In painting in water-colours, minium mixed with a little vermilion produces a good scarlet: but if a flower in a print is to be painted of a scarlet-colour, the lights as well as the shades should be covered with minium, and the shaded parts finished with carmine, which will produce an admirable scarlet.

SCARP, in fortification, is the the interior talus, or slope of the ditch next the place, at the foot of the rampart.

SCARP, in heraldry, the scarf which military commanders wear for ornament.

It is borne somewhat like a battoon snifter, but is broader than it, and is continued out to the edges of the field: whereas the battoon is cut off at each end. See Plate CXLVII. fig. 16.

SCARPANIO, an island in the Mediterranean, twenty miles south-west of Rhodes: E. long. 27°, N. lat. 36°.

SCARUS, in ichthyology. See **LABRUS**.

SCAVENGERS, two officers annually chosen in every parish in London and its suburbs by the church-wardens, constables, and other inhabitants, to hire persons called rakers, with carts, to clean the streets, and carry away the dirt and filth, with the ashes and dust from every house.

SCENE, in its primary sense, denoted a theatre, or the place where dramatic pieces and other public shews were exhibited: for it does not appear that the ancient poets were at all acquainted with the modern way of changing the scenes in the different parts of the play, in order to raise the idea of the persons represented by the actors being in different places.

The original scene for acting of plays was as simple as the representations themselves: it consisted only of a plain plot of ground proper for the occasion, which was in some degree shaded by the neighbouring trees, whose branches were made to meet together, and their vacancies supplied with boards, sticks, and the like; and to complete the shelter, these were sometimes covered with skins, and sometimes with only the branches of other trees newly cut down, and full of leaves. Afterwards more artificial scenes or scenical representations were introduced, and paintings used instead of the objects themselves. Scenes were then of three sorts; tragic, comic, and satyric. The tragic scene represented stately magnificent edifices, with decorations of pillars, statues, and other things suitable to the palaces of kings: the comic exhibited private houses with balconies and windows, in imitation of common buildings: and the satyric was the representation of groves, mountains, dens, and other appearances; and these decorations either turned on pivots, or slid along grooves, as those in our theatres.

Scene is also a part or division of a dramatic poem. Thus plays are divided into acts, and acts are again subdivided into scenes; in which sense the scene is properly the persons present at, or concerned in, the action on the stage at such a time: whenever, therefore, a new actor appears, or an old one disappears, the action is changed into other hands; and therefore a new scene then commences.

SCENIC GAMES, among the ancients, were entertainments exhibited on the scena or theatre, including plays, dancing, and other theatrical performances.

SCENOGRAPHY, in perspective, the representation of a body on a perspective plane; or, a description thereof in all its dimensions, such as it appears to the eye. See **PERSPECTIVE**.

SCEPTEK, a kind of royal staff, or battoon, borne by kings on solemn occasions, as an ensign of command and authority.

SCPTICISM, the doctrines and opinions of the sceptics, whose distinguishing tenet was that all things are uncertain and incomprehensible, and that the mind is never to assent to any thing, but to remain in perpetual doubt and suspense. This doctrine was also called *pyrrhonism*,

from the name of its author. See **PYRRHONIANS**.

SCHAFFHOUSE, the capital of the canton of Schaffhouse, one of the most northern cantons of Switzerland: E. long. 8° 46', N. lat. 47° 42'.

SCHALHOLT, the capital of Iceland, subject to Denmark: W. long. 19°, N. lat. 64° 30'.

SCHAMACHIA, a city of Persia, in the province of Chirvan, situated on the west side of the Caspian sea, in E. long. 50°, N. lat. 41°.

SCHELD, a river which rises in the confines of Picardy, and runs north-east by Cambrai, Valenciennes, Tournay, Oudenarde, &c. and receiving the Lis at Ghent, runs east by Dendermond, and then north to Antwerp: below which city it divides into two branches; one called the *Wester-Scheld*, which separates Flanders from Zealand, and discharges itself into the sea near Flushing: and the other called the *Oster-scheld*, which runs by Bergen-op-zoom, and afterwards between the islands Beveland and Schowen, and a little below falls into the sea.

SCHELLING, an island of Holland, at the entrance of the Zuyder sea, between Flie Island and Ameland: E. long. 5° 20', N. lat. 53° 34'.

SCHEMNITZ, capital of the mine towns in Upper Hungary, sixty miles north-east of Presburg.

SCHENECTIDA, a fortress of New-York, in America, situated on Hudson's River, in the province of Albany, a hundred miles north of New York city.

SCHETTLAND, about forty islands, which constitute part of the country of Orkney, or the Orkades, in Scotland, valuable on account of the herring-fishery on their shores: situated between 1° east and 2° west longitude, and between 61° and 62° of north latitude.

SCHIRAS, or **SHERAS**, a city of Persia, in the province of Fars, 180 miles south of Isfahan; reckoned the second city in that kingdom.

SCHISM, a separation, or breaking off from communion with any church; on account of some disagreement in matters of faith or discipline.

SCHOENUS, in botany, a genus of the triandria monogynia class. The glumæ are paleaceous, and have but one valve; it has no corolla, and but one round seed. The species are 13, five of them natives of Britain.

SCHOLASTIC, something belonging to the schools. See **SCHOOL**.

SCHOLIAST, a grammarian, who writes scholia, that is, notes, glosses, &c. upon ancient authors, who have written in the learned languages. See the next article.

SCHOLIUM, a note, annotation, or remark, occasionally made on some passage, proposition, or the like. This term is much used in geometry, and other parts of mathematics, where, after demonstrating a proposition, it is customary to point out how it might be done some other way, or to give some advice, or precaution, in order to prevent mistakes, or add some particular use, or application thereof.

SCHOOL, a public place, wherein the languages, or arts and sciences are taught. Thus we say, grammar-school, writing-school, &c.

SCHWALBACH, a town of Germany, in the circle of the Upper Rhine and in the territory of the Wetteraw, and county of Nassau, eight miles north of Mentz.

SCHWALBEA, in botany, a genus of the didymia angiospermia class. The calix consists of four segments, the

the superior tube being least, and the lowest largest.

There is but one species, a native of America.

SCHWARTSBURG, a town of Germany, in the circle of Upper Saxony, and landgrave of Thuringia, eight miles south-east of Gotha.

SCHWARTZENBURG, a town of Germany, in the circle of Franconia, twenty miles east of Wurtzburg.

SCHWATS, a town of Germany, in the county of Tyrol, situated on the river Inn, twenty miles north-east of Innsbruck.

SCHWEIDNITZ, a town of Bohemia, in the duchy of Silesia, capital of a duchy of the same name, situated twenty six miles south of Breslaw.

SCHWEINFURT, an imperial city of Germany, in the circle of Franconia, and bishopric of Wurtzburg, situated on the river Maine: in E. long. $10^{\circ} 15'$, N. lat. $50^{\circ} 15'$.

SCIÆNA, in ichthyology, a genus belonging to the order of thoracici. The membrane of the gills has six rays; the opercula and whole head are scaly. There are five species.

SCIARRI, in natural history, the matter which runs down in burning torrents from the craters of volcanos, and which probably contains mineral and metallic particles, it being ponderous and hard.

Some of the sciarrs are coarse, and others fine and polished on the surface; some of them are black, others grey, others reddish, and others of the colour of iron, and many of them have coverings of pure sulphur over their whole surface. They seem to be the result of many sorts of minerals melted together.

SCIATICA. See **MEDICINE**, p. 128.

SCIENCE, in philosophy, denotes any doctrine, deduced from self-evident and certain principles, by a regular demonstration.

SCILLA, the **SQUILL**, in botany, a genus of the hexandria monogynia class. The corolla consists of six open, deciduous petals; and the filaments resemble threads. There are eight species, two of them natives of Britain, viz. the bifolia, or vernal star-hyacinth; and the autumnalis, or lesser autumnal star-hyacinth.

The middle part of the root of the scilla maritima, a native of Spain, is only used in medicine: the apothecaries cut the root perpendicularly in two; and separating the heart and the outer parts, they expose the others to dry. This root is extremely acrid, attenuant, and dissolvent: it is apt to prove emetic in whatever form it is given; but this may be prevented, by adding a few grains of cinnamon to it; it then becomes a powerful medicine in all obstructions of the viscera; it promotes urine and the menses, and cuts the tough phlegm which almost chokes in asthma and many other disorders of the breast.

SCILLY, a cluster of islands and rocks, situated in the Atlantic ocean: W. long. 7° , N. lat. 50° .

SCIO, an island of Turkey, in the Archipelago, situated in E. long. 27° , N. lat. $38^{\circ} 15'$.

SCIOPTIC, a sphere, or globe of wood, with a circular hole or perforation, wherein a lens is placed. It is so fitted, that, like the eye of an animal, it may be turned round every way, to be used in making experiments of the darkened room.

SIRO, an island of Turkey, in the Archipelago, situated E. long. 25° , N. lat. $38^{\circ} 15'$.

SCIRPUS, in botany, a genus of the triandria monogynia class. The glumes are paleaceous and imbricated; it has no corolla, and but one beardless seed. The species are 27, ten of which are natives of Britain.

SCIRRHUS, in surgery and medicine, a hard tumour of any part of the body, void of pain, arising from the inspissation and induration of the fluids contained in a gland; though it may appear in any other part, especially in the fat, being one of the ways wherein an inflammation terminates. See **MEDICINE** and **SURGERY**.

SCIURUS the **SQUIRREL**, a genus of quadrupeds belonging to the order of glires. It has two fore-teeth in each jaw, the superior ones shaped like wedges, and the inferior ones compressed. There are eleven species. The vulgaris, or common squirrel, which is a native of most southern parts of Europe, has a pencil of hairs on the top of the ears, four toes on the fore-feet, and five on the hind ones: In the summer, it is of a reddish colour, with a white belly; in the winter, it is of a bluish ash-colour. The squirrel is a very active animal; it feeds upon nuts, berries, &c. which it carries to its mouth by the fore-feet: It lays up its superfluous food in holes; and makes a round nest of moss.

SCLAREA, in botany. See **SALVIA**.

SCLAVONIA, a province subject to the house of Austria, and bounded on the north-east by the rivers Drave and Danube, which separate it from Hungary; being about two hundred miles long, and sixty broad.

It takes its name from the Scavi, an ancient people of European Scythia; from whom is likewise derived the Sclavonic language, which is said to be the most extensive language in the world, except the Arabic; as being the common mother of the Russian, Hungarian, Polish, Bulgarian, Carinthian, Bohemian, &c. languages.

SCLERANTHUS, in botany, a genus of the decandria digynia class. The calix consists of one leaf; it has no corolla; and the seeds are two, inclosed in the calix. There are three species, two of them natives of Britain, viz. the annuus, german knot-grass, or annual knawel; and the perennis, or perennial knawel.

SCLEROTICA, in anatomy. See **ANATOMY**, p. 289. **SCLEROTICS**, medicines proper to harden and consolidate the flesh of the parts to which they are applied; as purslain, house-leek, flea-wort, garden night-shade, &c.

SCOLAPAX, in ornithology, a genus belonging to the order of gallix. The beak is cylindrical, obtuse, and longer than the head; the nostrils are linear; the face is covered; and the feet have four toes. There are 18 species.

SCOLOPENDRA, in zoology, a genus of insects belonging to the order of aptera. The feet are very numerous, being as many on each side as there are joints in the body; the antennæ are setaceous; there are two jointed pappi; and the body is depressed. There are eleven species.

SCOLYMUS, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is paleaceous; the calix is imbricated and prickly; and it has no pappus. There are two species, both natives of Italy.

SCOMBER, in ichthyology, a genus belonging to the order of thoracici. The head is smooth and compressed; and there are seven rays in the gill-membrane. The species are ten.

SCONE,

SCONE, or **Scoon**, a town of Scotland, near Perth, remarkable for being the place where the kings of Scotland were crowned.

SCOPARIA, in botany, a genus of the tetrandria monogynia class. The calix consists of four segments; the corolla is rotated, with four segments; and the capsule has one cell, and two valves, containing many seeds. There are two species, none of them natives of Britain.

SCOPER, or **SCUPER-HOLES**, in a ship, are holes made through the planks, close to the deck, to carry off the water that comes from the pump.

SCORBUTUS, the **SCURVY**. See **MEDICINE**, p. 106.

SCORDIUM. See **TEUTURIUM**.

SCORIA, or **DROSS**, among metallurgists, is the remains of metals in fusion; or, more determinately speaking, is that mass which is produced by melting metals and ores, and when cold is brittle, and not dissoluble in water; being properly a kind of glass.

SCORIFICATION, in metallurgy, is the art of reducing a body, either entirely, or in part, into scoria.

SCORPENA, in ichthyology, a genus belonging to the order of thoracici. The head is large and sharp; the eyes are near each other; there are teeth in the jaws, palate and fauces; and there are seven rays in the membrane of the gill. The species are three.

SCORPIO, in zoology, a genus of insects belonging to the order of aptera. It has eight feet, besides two frontal claws; the eyes are eight in number, three on each side of the thorax, and two on the back; it has two claw-shaped palpi, a long jointed tail, with a pointed weapon at the extremity; it has likewise two combs situate betwixt the breast and abdomen. There are six species, all natives of southern climates.

SCORPIO, in astronomy. See **ASTRONOMY**, p. 487.

SCORPIURUS, in botany, a genus of the diadelphica decandria class. The pedicel is cylindrical, revolute, and intercepted with isthmus. There are four species, none of them natives of Britain.

SCORZONERA, in botany, a genus of the syngenesia polygamia equalis class. The receptacle is naked; the pappus is plumose; and the calix is imbricated with scales membranaceous at the edges. There are 11 species, none of them natives of Britain.

SCOT, a customary contribution laid upon all subjects according to their abilities. Whoever were assessed to any contribution, though not by equal portions, were said to pay foot and lot.

SCOTIA, in architecture, a semicircular cavity or channel between the torus, in the bases of columns. See **ARCHITECTURE**.

SCOTISTS, a sect of school-divines and philosophers, thus called after their founder J. Duns Scotus, a Scotch cardinal, who maintained the immaculate conception of the virgin, or that she was born without original sin, in opposition to Thomas Aquinas and the Thomists.

SCOTLAND, exclusive of the islands, is situated between 1° and 6° W. long, and between 54° 30' and 58° 30' N. lat. being about three hundred miles long from north to south, and from fifty to one hundred and fifty miles broad, from east to west.

Since the union with England, Scotland is divided into thirty-three shires, or counties, which all together send only thirty knights to parliament, by reason the shires of

Bute and Cathness chuse only alternately, or every other parliament, in their turns; as do those of Cromarty and Nairn, Clackmannan and Kinross.

The royal boroughs of Scotland are sixty-five, but so classed as to send only fifteen burghs to parliament.

NEW SCOTLAND, *Nova Scotia*, one of the British colonies in North America, is situated between 62° and 72° W. long, and between 43° and 51° N. lat. being bounded by the river of St. Lawrence on the north and north-west; by the bay of St. Lawrence, and the Atlantic Ocean, on the east; by the same ocean, and New-England, on the south; and by Canada, on the west.

SCOTOMIA, in medicine, a dizziness or swimming in the head, wherein the animal spirits are so worried about, that external objects seem to turn round.

SCRATCH PANS, in the English salt-works, a name given to certain leaden pans, which are usually made about a foot and half long, a foot broad, and three inches deep, and have a bow, or circular handle of iron, by which they may be drawn out with a hook, when the liquor in the pan is boiling.

The use of these pans is to receive a calcareous earth, of the nature of that which incrusts our tea kettles, which separates from the water in boiling; this substance they call *scratch*; and these pans, being placed at the corners of the salt pan, where the heat is least violent, catch it as it subsides there.

SCREW, one of the six mechanical powers. See **MECHANICS**, p. 49.

SCRIBE, an officer among the Jews whose business was to write; of which there were three kinds: the first and principal of which were the scribes of the law, whose office was to write and interpret scripture; these were in great credit and esteem among the Jews, and had even the precedence of the priests and sacrificers, and their decisions were received with almost the same respect as the law of God itself: the second kind, properly called scribes of the people, were a sort of magistrates; and the third were public notaries, or secretaries of the council; which were the least considerable.

The scribes, among the Romans, wrote out decrees, or acts, and made out authentic copies of them.

SCRIBING, in joinery, &c. is a term used when one side of a piece of stuff is to be fitted to another that is irregular.

SCRIPTURE, an appellation given, by way of eminence, to the sacred and inspired writings of the Bible. See **BIBLE**.

SCROPHULA, in medicine. See **MEDICINE**, p. 137, &c.

SCROPHULARIA, in botany, a genus of the didynamia angiospermia class. The calix has five segments; the corolla is somewhat globular; and the capsule has two cells. There are 14 species, four of them natives of Britain, viz. the nodosa, or knobby-rooted figwort; the aquatica, or water figwort; the scorodonia, or balm-leaved figwort; and the vernalis, or yellow figwort.

SCROTUM, in anatomy. See **ANATOMY**, p. 271.

SCRUPI, in natural history, fossils, formed into large detached masses without crusts, and composed of a variously debased crystalline matter.

SCRUPLE, a weight equal to the third part of a dram, or to twenty grains.

SCRUTINY, a strict examination of any thing.

SCULPTURE, an art by which, in taking away, or adding to matter, all sorts of figures are formed by the hand, either in the stone, wood, wax, or metal. In its full latitude it signifies both the art of working in creux, properly called engraving; and of working in relief, which is more strictly called sculpture.

The first works in sculpture were with clay, not only in making statues, but in forming models; and to this day a sculptor never undertakes any thing considerable, without forming a model, either in clay or wax. In making figures of these materials, they begin and finish their work with their hands, using only three or four pieces of wood, which are roundish at one end, and at the other flat, with a sort of claws and teeth, which are to smooth and scratch the work. For waxen models to every pound of wax add half a pound colophony: some add turpentine, and melt it together with oil of olives; more or less of the latter being used as they would have the matter harder or softer: some also add a little vermilion, to give it a colour: this is wrought and moulded with the fingers like clay.

For sculpture in wood, which we properly call carving, the first thing required is to chuse wood proper for the work the sculptor is to perform. If it be any thing large, and that requires a great deal of strength and solidity, the hardest and most durable wood is to be chosen; and for smaller works and ornaments, the softer wood is used; but it must be such, however, as is firm and close: for a large work, though it be only a single figure, it is better to make use of several pieces of wood, or bits of board, glued together, than of one whole piece, which is more liable to crack: for a thick piece of wood may not be dried to the heart, however it may appear on the outside.

In sculpture in marble and other stone, the first thing to be done is to saw out a block of marble, of the bigness of the work to be performed; and this being done, the superfluities are to be taken off by a fluted point and a heavy mallet; thus bringing it near the measures required, the sculptor reduces it still nearer with a finer tool, called a dog's tooth, it having two points, but one not so sharp as the other. After this he makes use of his gradine, which is a flat cutting tool, with three teeth; he then takes off, with a smooth chissel, the scratches the gradine left on the marble, and uses it with dexterity and delicacy, to give softness and tenderness to his figure; till at length, taking rasps of different degrees of fineness, the work is gradually rendered fit for polishing. To polish the work, the sculptor uses pumice-stone and smalt; then he goes over it with tripoli; and when he would give it more lustre, rubs it with leather and straw ashes. There are several other tools used by sculptors, adapted to the different parts of the work, and the nature of the stone they make use of. As the models of clay shrink as they grow dry, whenever sculptors undertake a considerable piece of work, they only use the model for making a mould of plaster or stucco, in which is formed a figure of the same matter, which serves them thenceforth for a model, and by which they adjust all their measures and proportions. To proceed the more regularly, on the head of the model they place an immovable circle divided into degrees, with a moveable rule or index, fixed in the centre of the circle, and divided also into e-

qual parts: from the end of the rule hangs a line with a plummet, which serves to take all the points, to be transferred thence to the block of marble, from whose top hangs another plummet, like that of the model. But there are some excellent sculptors who disapprove of this method; urging, that the smallest motion of the model changes their measures, for which reason they chuse rather to take all their measures with the compasses.

SCUM, properly denotes the impurities which a liquor, by boiling, casts up to the surface.

The term *scum* is also used for what is more properly called the scoria of metals.

SCURVY, in medicine. See **MEDICINE**, p. 106.

SCURVY GRASS, in botany. See **COCHLEARIA**.

SCUTELLARIA, in botany, a genus of the didynamia gymnosperma class. The calix is entire on the edge, is shut after the flowering, and operculated. The species are 13, two of them natives of Britain, *viz.* the galericulata, or hooded willow-herb; and the minor, or lesser hooded willow herb.

SCUTIFORME os. in anatomy, the same with rotula. See **ANATOMY** p. 185.

SCUTIFORMIS CARTILAGO, in anatomy, the same with the thyroid cartilage. See **ANATOMY**, p. 300.

SCUTTLES, in a ship, square holes cut in the deck, big enough to let in the body of a man, serving to let people down into any room below upon occasion, or from one deck to another.

SCYTHIA. The northern parts of Europe and Asia were anciently so called, which afterwards obtained the name of Tartary.

SEA. is frequently used for that vast tract of water encompassing the whole earth; but is more properly a part or division of these waters, and is better defined a lesser embayment of water, which lieth before and washeth the coasts of some particular countries from whence it is generally denominated, as the Irish sea, the Mediterranean sea, the Arabian sea, &c.

What proportion the superficies of the sea bears to that of the land is not precisely known, though it is said to be somewhat more than two thirds. As the waters of the earth must necessarily rise to the surface thereof, as being specifically lighter than the earth, it was necessary there should be large cavities therein for receptacles to contain them; otherwise they would have overspread all the superficies of the earth, and so have rendered it utterly uninhabitable for terrestrial animals. For the centre of the earth being the common centre of gravity, and the nature of fluids being such that they equally yield to equal powers, and the power of attraction being every where equal at equal distances from the centre, it follows, that the superficial parts of the water will every where conform themselves to an equidistant situation from the centre, and consequently will form the surface of a sphere so far as they extend. Hence, that the sea seems higher than the earth or land, results from the fallacy of vision, whereby all objects, and the parts of land as well as sea, the farther they are off from us, the higher they appear; the reason of all which is plain from optics: for it is well known, that the denser any medium is through which we behold objects, the greater is the refraction, or the more their images appear above the horizontal level; also the greater quantity of the medium the rays pass through, the

the more will they be bent from their first direction: on both these accounts the appearances of things remote, and on the sea, will be somewhat above the horizon, and the more so as they are the more remote.

With regard to the depth or profundity of the sea, Vauvenus affirms, that it is in some places unfathomable, and in other places very various, being in certain places ३०० ४ ५ ६ ७ ८ ९ १० २० ४० ६० English miles, in other places deeper, and much less in bays than in oceans. In general, the depths of the sea bear a great analogy to the height of mountains on the land, so far as is hitherto discovered.

There are two principal reasons why the sea doth not increase by means of rivers, &c. falling every where into it. The first is, because waters return from the sea by subterranean cavities and aqueducts, through various parts of the earth. Secondly, because the quantity of vapours raised from the sea, and falling on the land, only cause a circulation, but no increase of water. It hath been found by calculation, that in a summer's day there may be raised in vapours, from the M-diterranean sea. 5280000000 tons of water; and yet this sea receiveth not, from all its nine great rivers, above 1927000000 tons per day, which is but a third part of what is exhaled in vapours.

With regard to the faltness of the sea-water, it is very rationally judg'd to arise from great multitudes both of mines and mountains of salt, dispersed here and there in the depths of the sea. Dr Halley supposes that it is probable the greatest part of the sea salt, and of all salt lakes, as the Caspian sea, the Dead sea, the lake of Mexico, and the Titicaca in Peru, is derived from the waters of the rivers which they receive : and since this sort of lakes has no exit or discharge, but by the exhalation of vapours ; and also since these vapours are entirely fresh, or devoid of such particles ; it is certain the faltness of the sea and such lakes must, from time to time increase, and therefore the faltness at this time is greater than at any time heretofore. He further adds, that if, by experiments made in different ages, we could find the different quantity of salt which the same quantity of water (taken up in the same place, and in all other the same circumstances) would afford, it would be easy from thence, by rules of proportion, to find the age of the world very nearly, or the time wherein it has been acquiring its present faltness.

With regard to the use of this falt property of sea-water, it is observed, that the faltness of the sea preserves its waters pure and sweet, which otherwise would corrupt and think like a filthy lake, and consequently that none of myriads of creature that now live there n could then have a being. From thence also the sea-water becomes much heavier, and therefore ships of greater size and quantity may be used thereon. Salt water also doth not freeze so soon as fresh water, whence the seas are more free for navigation. We have lately had published a dissertation, by Dr Ruissel, concerning the medical uses of sea-water in diseases of the glands, &c. wherein the author premises some observations upon the nature of sea-water, considered as impregnated with particles of all the bodies it passes over, such as sub marine plants, fish, salts, minerals, &c. and saturated with their several effluvia, to enrich it, and keep it from putrefaction : hence this fluid is supposed to contract a soapiness, and the whole collection, being pervaded by the sulphurous steams passing through it, to

constitute what we call sea water, the confessed distinguishing characteristics of which are saltness, bitterness, nitrosity, and unctuality: whence the author concludes, that it may be justly expected to contribute signally to the improvement of phytic. The cases in which our author informs us we are to expect advantage from sea water, are, 1. In all recent obstructions of the glands of the intestines and mesentery. 2. All recent obstructions of the pulmonary glands, and those of the viscera, which frequently produce consumptions. 3. All recent glandular swellings of the neck, or other parts. 4. Recent tumours of the joints, if they are not suppurated, or become scirrhus, or cancerous, and have not carious bones for their cause. 5. Recent defluxions upon the glands of the eye-lids. 6. All defecations of the skin, from an erysipelas, to a lepra. 7. Diseases of the glands of the nose, with their usual companion a thickness of the lip. 8. Obstructions of the kidneys, where there is no inflammation, and the stone not large. 9. In recent obstructions of the liver this method will be proper, where it prevents constipations of the belly, and assists other medicines directed in icteric cases. The same remedy is said to be of signal service in the bronchocele; and is likewise recommended for the prevention of those bilious colics that so frequently affect our mariners.

To make sea-water fresh is a thing long and much wanted, for the advantage of navigation and commerce ; a method for doing which has been long ago invented by Mr Hutton, and the secret published in the Philoſ. Tranſact. It is performed by precipitating the water with oil of tartar, and then diſtilling it. But Mr Appleby's proceſs, which was relerred by the lords of the admiralty to the college of phyſicians, and communicated to the royal ſociety, with ſome experiments therewith, on Feb. 8, 1753, appears to be more ſucceſſful, and is performed thus : Into twenty gallons of ſea-water put fix ounces of a fixed alkali prepared with quick lime as ſtrong as lapis infernalis, and fix ounces of bones calcined to a whitenefs, and finely powdered; with a ſlow fire, draw off, in a common ſtill fifteen gallons. Mr Appleby conceives that the alkali here employed is the beſt adapted to prevent the bituminous matter in ſea water from riſing by heat in diſtillation.

In the year 1755, a method of procuring any quantity of fresh water at sea was published by Dr Butler; together with a method also of preserving fresh water entirely pure, sweet, and wholesome, during the longest voyage, and in the warmest climates. The method more expressly recommended by the doctor for making sea-water fresh is to put a measured wine-quart of the strongest soap leys to fifteen gallons of sea-water; which being distilled, he assures us, will generally yield twelve gallons of fresh water. The above quantity of soap leys, we are told, will bear a repetition of the same quantity of water four or five times.

This method of Dr Butler was tried, by order of the lords of the admiralty, at the same time with Mr Appleby's : but the latter, being found to be performed with a less quantity of fuel, was preferred.

In order to keep fresh water sweet, Dr Butler directs to take of fine, clear, white pearl-ashes, a quarter of a pound avoirdupoise. and put into one hundred gallons of fresh water; observing this proportion to a greater or less quantity.

quantity, and stop up your cask as usual, till you have occasion to broach it.

For the ebbing and flowing of the sea, see *ASTRONOMY*, p. 473.

SEAMEN, such as are referred to serve the king, or other persons, at sea, who may not depart without license, &c. Seamen fighting, quarrelling, or making any disturbance, may be punished by the commissioners of the navy with fine and imprisonment. Registered seamen are exempted from serving in any parish office &c. and are allowed bounty-money besides their pay. By the law of merchants, the seamen of a vessel are accountable to the master or commander, and the master to the owners, and the owners to the merchants, for damage sustained either by negligence or otherwise. Where a seaman is hired for a voyage, and he deserts it before it is ended, he shall lose his wages; and in case a ship be lost by a tempest, or in a storm, the seamen lose their wages, as well as the owners their freight.

SEAFORD, a port-town of Sussex, situated on the English channel, seven miles south of Lewes. It sends two members to parliament.

SEAL, a punchoon, or piece of metal, or other matter, usually either round or oval, whereon are engraven the arms, device, &c. of some prince, state, community, magistrate or private person, often with a legend or subscription, the impression whereof in wax serves to make acts, instruments, &c. authentic.

SEAL is also used for the wax or lead, and the impression thereon, affixed to the thing sealed.

SEAL, in Scots law. See *LAW*, Tit. xii. 25.

SEALER, an officer in chancery appointed by the lord chancellor or keeper of the great seal to seal the writs and instruments there made in his presence.

SEALING, in architecture, the fixing a piece of wood or iron in a wall with plaster, mortar, cement, lead, and other solid binding. For staples, hinges and joints, plaster is very proper.

SEALING-WAX. See *WAX*.

SEAM or **SEME** of corn, is a measure of eight bushels.

SEAM of glass, the quantity of 100 pound or 24 stones each five pounds weight. The seam of wood is an horse-load.

SEAR CLOTH, or **CERE-CLOTH**, in surgery, a form of external remedy somewhat harder than an unguent, yet softer than an emplaster, though it is frequently used both for the one and the other. The sear-cloth is always supposed to have wax in its composition, which distinguishes and even denominates it. In effect, when a liniment or unguent has wax enough in it, it does not differ from a sear-cloth.

SEASIN, in a ship, the name of a rope by which the boat rides by the ship's side when in harbour, &c.

SEASONS, in cosmography, certain portions or quarters of the year, distinguished by the signs which the earth then enters, or by the meridian altitudes of the sun, consequent on which are different temperatures of the air, different works in tillage, &c. The year is divided into four seasons: spring, summer, autumn, and winter. See *ASTRONOMY*, p. 546.

St. SEBASTIAN, a port-town of Spain, in the province of Biscay, and territory of Guipúzcoa: situated in W. long. 1° 50'. N. lat. 43° 35'.

SECALE, **Rye**, in botany, a genus of the triandria digy-

nia class. The involucre consists of two leaves, and contains two flowers. There are four species, only one of them, viz. the villolum, or wood rye-grass, a native of Britain. For the cerealia, or common rye cultivated in our fields, see *AGRICULTURE*, p. 61.

SECANT, in geometry, is a line that cuts another, or divides it into two parts.

SECEDERS, a sect of P. esbyterians, who dissented from the established church of Scotland in the year 1723. The following circumstance gave rise to this sect. Mess. Basking, Wilton Moncreiff, and Fisher, ministers of the church of Scotland, oblatinately refused, for several years, to obey the decisions of the General Assembly with regard to the settlement of ministers agreeably to the law of patronage: For this open contempt of authority, the Assembly, after many and repeated admonitions, were at last obliged to eject them from their respective charges. These four clergymen, when they saw matters carried this length, immediately complained of persecution, protested uncommon sanctity and austerity of manners; and cried out that the church was over-run with various errors, such as, a compliance with the law of patronage, the tenderness of the assembly to Professors Simson and Campbell, who were accused of Arrian and Arianian heresies; and a multitude of practical deviations from the covenanted reformation of Scotland: They even inveighed against the conduct of the government for their ready admission of malignant and wicked men into places of trust in the army and state, for the loose and unlimited restoration of Charles II. to the throne, for the restoration of prelacy in England, which had been solemnly abjured; for restoring the superstitious Christmas vacance; for the repeal of the penal laws against witches, &c. &c. These things, joined to the popular talents of some of the above ministers, alarmed the minds of many well-meaning people, and in a few years procured a numerous train of followers. Elated with this unexpected success, they soon split into two parties. The chief point of contest among the leaders of this sect was concerning the lawfulness of what is called the burghers-oath; and hence the one party have ever since been called *Burghers*, and the other *Antiburghers*. This division naturally weakened their cause, and diminished their number, which still seems to be upon the decline.

SECOMIÆ, in natural history, the name of a genus of fossils, of the class of the septaria, the characters of which are; that they are bodies of a dusky hue, divided by septa, or partitions of a sparry matter, into several more or less regular portions, of a moderately firm texture, not giving fire with steel, but fermenting with acid menstrua and easily calcining.

The septaria of this genus are, of all others, the most common, and are what have been known by the title expressive, or mistaken names of the waxen vein, or ludus helmontii. We have many species of these bodies common among us. Of the whitish or brownish kinds we have thirteen; of the yellowish five; and of the ferruginous ones, four.

SECOND, in geometry, chronology, &c. the sixtieth part of a prime or minute, whether of a degree, or of an hour. **Second**, in music, one of the musical intervals; being only the difference between any sound and the next nearest sound, whether above or below it.

SECON-

SECONDARY, in general, something that acts as second, or in subordination to another.

SECRETARY, an officer who by his master's orders writes letters, dispatches, and other instruments, which he renders authentic by his signet. Of these there are several kinds; *as*, 1. Secretaries of state, who are officers that have under their management and direction the most important affairs of the kingdom, and are obliged constantly to attend on the king: they receive and dispatch whatever comes to their hands, either from the crown, the church, the army, private grants, pardons, dispensations, &c. as likewise petitions to the sovereign; which when read, are returned to them; all which they dispatch according to the king's direction. They have authority to commit persons for treason, and other offences against the state, as conservators of the peace at common law, or as justices of the peace throughout the kingdom. They are members of the privy-council, which is seldom or never held without one of them being present; and as to the business and correspondence in all parts of this kingdom, it is managed by either of the secretaries without any distinction: but with respect to foreign affairs, the business is divided into two provinces, or departments, the southern and the northern, comprehending all the kingdoms and states that have any intercourse with Great Britain; each secretary receiving all letters and addresses from, and making all dispatches to, the several princes and states comprehended in his province. Ireland and the Plantations are under the direction of the elder secretary, who has the southern province, which also comprehends France, Italy, Switzerland, Spain, Portugal, and Turkey: the northern province includes the Low Countries, Germany, Denmark, Sweden, Poland, and Muscovy. Each of the secretaries have an apartment in all the royal houses, both for their own accommodation and their officers; they have also a table at the king's charge, or else board-wages. The two secretaries of state have each two under secretaries, and one chief clerk, with an uncertain number of other clerks and translators, all wholly depending on them. To the secretaries of state belong the custody of that seal properly called the signet, and the direction of two other offices, one called the paper-office, and the other the signet-office. 2. Secretary of an embassy, a person attending an ambassador for writing dispatches relating to the negotiation. There is a great difference between the secretary of an embassy, and the ambassador's secretary; the last being a domestic or menial of the ambassador, and the first a servant or minister of the prince. 3. The secretary of war, an officer of the war-office, who has two chief clerks under him, the last of which is the secretary's messenger. There are also secretaries in most of the other offices.

SECRETION, the separation of some fluid from the blood by means of the glands.

In the bodies of animals we observe a great number of juices of different natures. *viz* the blood, lymph, saliva, stomach liquor, intestinal juices, pancreatic juice, bile, urine, &c. and the blood is the general source of all. See **BLOOD**, **LYMPH**, **SALIVA**, &c.

SECT, a collective term, comprehending all such as follow the doctrines and opinions of some famous divine, philosopher, &c.

SECTION in general, denotes a part of a divided thing,

or the division itself. Such, particularly, are the subdivisions of a chapter; called also paragraphs and articles: the mark of a section is §.

SECTION, in geometry denotes a side or surface appearing of a body or figure cut by another; or the place where lines, planes, &c. cut each other.

SECTOR, in geometry, is a part of a circle comprehended between two radii and the arch; or it is a mixed triangle, formed by two radii and the arch of a circle.

SECTOR is also a mathematical instrument, of great use in finding the proportion between quantities of the same kind, as between lines and lines, surfaces and surfaces, &c. for which reason the French call it the compass of proportion.

The great advantage of the sector above common scale, &c. is, that it is adapted to all radii, and all scales. For, by the line of chords, sines, tangents, &c. on the sector, we have lines of chords, sines, tangents, &c. adapted to any radius betwixt the length and breadth of the sector, when opened.

The sector is founded on the fourth proposition of the sixth book of Euclid, where it is demonstrated, that similar triangles have their homologous sides proportional. **SECULAR**, something that is temporal; in which sense, the word stands opposed to ecclesiastical: thus we say, secular power, secular jurisdiction, &c.

SECULAR GAMES, *ludi seculares*, in antiquity, solemn games held among the Romans once in an age. These games lasted three days and as many nights, during which time sacrifices were performed, theatrical shews exhibited, with combats, sports, &c. in the circus. The occasion of these games, according to Valerius Maximus, was to stop the progress of a plague. The first who had them celebrated at Rome was Valerius Publicola, the first consul created after the expulsion of the kings. The ceremonies to be observed therein were found prescribed in one of the books of the Sibyls. At the time of the celebration of the secular games, heralds were sent throughout all the empire, to intimate that every one might come and see those solemnities which he never yet had seen, nor was ever to see again. Authors are not agreed as to the number of years wherein these games returned, partly because the quantity of an age or seculum among the ancients is not known, and partly on other accounts; some will have it that they were held every hundred years, and that the seculum or age was our century.

SECULARIZATION, the act of converting a regular person, place, or benefice, into a secular one.

SECUNDINES, in anatomy, the several coats or membranes wherein the foetus is wrapped up in the mother's womb, as the chorion and amnios, with the placenta, &c. See **MIDWIFERY**.

SECURIDACA, in botany, a genus of the diadelphia decandria class. The calix consists of three leaves; the corolla is papilionaceous, with a vexillum; and the pod is oval, and contains one seed. There are two species, both natives of America.

SECUTORES, in antiquity, a kind of gladiators among the Romans, who fought against the retiarii. The secutores were armed with a sword and a buckler, to keep off the net or noose of their antagonists, and they wore a calk on their head.

This was also a name given to such gladiators as took the place of those killed in the combat, or who fought the conqueror.

SEDAN, a town of Champagne, in France, situated on the river Maes : in E. long. $4^{\circ} 45'$. N. lat. $49^{\circ} 46'$.

SEDERUNT, in Scots law. See **LAW**, Tit. i. 4.

SEDIMENT, the settlement or dregs of any thing, or that gross heavy part of a fluid body which, upon resting, sinks to the bottom of the vessel.

SEDITION, in Scots law. See **LAW**, Tit. xxxiii. 13.

SEDR, or **SEDRS**, the high priest of the sect of Ali among the Persians. The sedr is appointed by the emperor of Persia, who usually confers the dignity on his nearest relation. The jurisdiction of the sedr extends over all effects destined for pious purposes, over all mosques, hospitals, colleges, sepulchres, and monasteries. He disposes of all ecclesiastical employments, and nominates all the superiors of religious houses. His decisions in matters of religion are received as so many infallible oracles ; he judges of all criminal matters in his own house without appeal. His authority is balanced by that of the muditehid, or first theologue of the empire.

SEDUM, in botany, a genus of the decandria pentagynia class. The calix consists of five segments, and the corolla of five petals ; it has five nectariferous scales at the base of the germen, and five capsules. There are 19 species, nine of them natives of Britain, all orpines and house-leeks.

SEED, in physiology, a substance prepared by nature for the reproduction and conservation of the species both in animals and plants. See **GENERATION**, and **AGRICULTURE**, p. 40.

SEEDLINGS, among gardeners, denote such roots of gilliflowers, &c. as come from seed sown. Also the young tender shoots of any plants that are newly sown.

SEEDY, in the brandy trade, a term used by the dealers, to denote a fault that is found in several parcels of French brandy, which renders them unsaleable. The French suppose that these brandies obtain the flavour which they express by this name from weeds that grow among the vines from whence the wine of which this brandy is made was pressed.

SEEING, the act of perceiving objects by the organ of sight ; or it is the sense we have of external objects by means of the eye. See **OPTICS**.

SEELING, in the manege. A horse is said to feel when he begins to have white eye brows, that is, when there grows on that part about the breadth of a farthing of white hairs, mixed with those of his natural colour, which is a mark of old age. It is said, that a horse never feels till he is fourteen years old, and always does before he is sixteen years.

SEELING, at sea, is used in the same sense nearly with heeling : when a ship lies down constantly, or steadily on one side, the seamen say she heels ; and they call it feeling when she tumbles violently and suddenly, by reason of the sea forsaking her, as they call it, that is, the waves leaving her for a time in a bowling sea.

SEGEDIN, a city of Upper Hungary, situated on the river Teyssle, in E. long. 21° . N. lat. $46^{\circ} 21'$.

SEGESWAE, a city of Transylvania, situated E. lon. 24° . N. lat. $47^{\circ} 25'$.

SEGMENT of a circle, in geometry, that part of the circle contained between a chord and an arch of the same circle.

SEGOVIA, a city of Manila, the largest of the Philippine islands, situated in E. long. 119° . N. lat. $18^{\circ} 30'$.

This is also a name of a city of Spain, in the province of Old Castile, situated W. long. $4^{\circ} 35'$. N. lat. 41° .

SEGRA, a river of Spain, which rising in the north of Catalonia, and running south-west, discharges itself into the Ebro, at Miquenena.

SEGREANT, is the herald's word for a griffon, when drawn in a leaping posture, and displaying his wings as if ready to fly.

SEGUE, in the Italian music, is often found before *aria*, *alleluja*, *amen*, &c. to shew that those portions or parts are to be sung immediately after the last note of that part over which it is writ ; but if these words *si piace*, or *ad libitum*, are joined therewith, it signifies, that these portions may be sung or not, at pleasure.

SEGURA, a town of Portugal, in the province of Beira, ten miles north-west of Alcantara. This is also the name of a town in Spain, in the province of New Castile, and territory of La Mancha, situated among the mountains of Segura ; W. long. $2^{\circ} 50'$. N. lat. $38^{\circ} 25'$.

SEJANT, a term used in heraldry, when a lion, or other beast, is drawn, in an escutcheon, sitting like a cat, with his fore-feet strait.

SEIZURE, in commerce, an arrest of some merchandize, moveable, or other matter, either in consequence of some law, or of some express order of the sovereign.

SEISIN, in Scots law. See **LAW**, Tit. x. 16.

SELAGO, in botany, a genus of the didymia angiospermia class of plants. The calix has five segments ; the tube of the corolla is capillary ; and there is but one seed. The species are eight, none of them natives of Britain.

SELBY, a town of Yorkshire, situated ten miles south of York.

SELENDERS, in the manege, are chops, or mangy fores, in the bending of a horse's hough, as the malenders are in the knees. See **FARRIER**.

SELENITÆ, **MOON STONE**, in natural history, a class of fossils, naturally and essentially simple ; not inflammable nor soluble in water ; composed of slender filaments, ranged into fine and even thin flakes, and those disposed into regular figures, in the different genera, approaching to a rhomboide, a hexangular column, or a rectangled inequilateral parallelogram ; fissile like the talcs, but that not only horizontally, but perpendicularly also ; flexible in a small degree, but not at all elastic ; not fermenting with acid menstrua, and readily calcining in the fire.

SELENOGRAPHY, a branch of cosmography, which describes the moon and all the parts and appearances thereof, as geography does those of the earth.

SELEUCIDÆ, in chronology. *Æra* of the Seleucids, or the Syro-macedonian æra, is a computation of time commencing from the establishment of the Seleucidæ, a race of Greek kings, who reigned as successors of Alexander the Great in Syria, as the Ptolomies did in Egypt. This æra we find expressed in the book of the Maccabees, and on a great number of Greek medals struck by the cities of Syria, &c. The Rabbins call it the æra of contracts ; and the Arabs, Therik dilmarnain, that is, the æra of the two horns. According to the best accounts, the first year

year of this æra falls in the year 311 before Christ, being twelve years after Alexander's death.

SELINGENSKOY, a town of Asiatic Muscovy, in the province of Siberia, situated on the road from Tobolski to China, on the river Selinga: in E. long. 65°, N. lat. 50°.

SELINUM, in botany, a genus of the pentandria digynia class. The fruit is somewhat oval, and striated in the middle; the involucrem is reflected; and the petals are equal and cordate. There are four species, none of them natives of Britain.

SELKIRK, a borough town of Scotland, in the county of Tweedale, situated 32 miles south of Edinburgh.

SELLA TURCICA. See **ANATOMY**, p. 149.

SELTZER WATER, the name of a mineral water of Germany, which arises near Neider Seltz, and is now used in England and many other countries. We call it feltz, or saltzer water; and the physicians prescribe it in many cases, as feurries, spasmodic affections, and in consumptions; in the last case, mixing it with asses milk.

SEMIOTICA, that part of medicine which considers the signs or indications of health and diseases, and enables the physician to judge what is, was, or will be, the state, degree, order, and effect, of health or sickness.

SEMIENDRIA, a town of European Turkey, in the province of Servia, situated on the Danube, thirty miles south-east of Belgrade.

SEMENTINEÆ FERIÆ, in antiquity, feasts held annually among the Romans, to obtain of the gods a plentiful harvest. They were celebrated in the temple of Tellus, where solemn sacrifices were offered to Tellus and Ceres. These feasts were held about seed-time, usually in the month of January; for Macrobius observes, they were moveable feasts.

SEMI, a word borrowed from the Latin, signifying *half*, but only used in composition with other words, as in the following articles.

SEMI-CIRCLE, in geometry, half a circle, or that figure comprehended between the diameter of a circle and half the circumference.

SEMI-COLON, in grammar, one of the points or stops used to distinguish the several members of sentences from each other. See **PUNCTUATION**.

The mark or character of the semi-colon is (;) and has its name as being somewhat of less effect than a colon, or as demanding a shorter pause.

SEMI-CUPIUM, in medicine, an half bath, wherein the patient is only placed up to the navel.

SEMI-DIAMETER, half the diameter, or a right line drawn from the centre of a circle, or sphere, to its circumference; being the same with what is otherwise called the radius.

SEMI-FLOSCULUS, in botany, a term used to express the flowers of the syngenesia class. These semiflosculus are petals, hollow in their lower part, but in their upper flat, and continued in the shape of a tongue.

SEMIGALLIA, the eastern division of the duchy of Courland in Poland.

SEMI-INTEROSSEUS INDICIS, in anatomy. See **ANATOMY**, p. 204.

SEMI-LUNAR VALVES, in anatomy. See **ANATOMY**, p. 178.

SEMI-MEMBRANOSUS, in anatomy. See **ANATOMY**, p. 208.

SEMI-PELAGIANS, in church history, a branch of the Pe-

lagians, so called because they pretended to keep a medium between the Pelagians and the orthodox.

SEMI-TONE, in music, one of the degrees or concinnous intervals of concords.

SEMINAL, something belonging to the semen or seed.

SEMINARY, a kind of college, or school, where youth are instructed in the ceremonies, &c. of the sacred ministry, of which there are many abroad; it being ordained by the council of Trent, that there be a seminary belonging to each cathedral, under the direction of the bishop.

SEMINATION, denotes the manner, or act, of shedding and dispersing the seeds of plants. See **AGRICULTURE**, p. 59.

SEMI-NERVOSUS, in anatomy. See **ANATOMY**, p. 208.

SEMI, in Roman antiquity, the half of an *as*. See **AS**.

SEMI-SPINALIS, in anatomy. See **ANATOMY**, p. 218.

SEMPERVIVUM, in botany, a genus of the dodecandria dodecagynia class. The calix consists of twelve segments, and the corolla of twelve petals; and there are twelve capsules containing many seeds.

SENA, in botany. See **CASSIA**.

Sena leaves are much used for their purgative virtue; but are apt to gripe, unless given with proper correctives, as coriander, aniseed, ginger, raisins, and salt of tartar, which are added to the infusion of the leaves occasionally.

SENATE, in general, is an assembly, or council, of senators; that is, of the principal inhabitants of a state, who have a share in the government.

The senate of ancient Rome is, of all others, the most celebrated: it exercised no contentious jurisdiction, but appointed judges, either from among the senators or knights, to determine processes: it also appointed governors of provinces, and disposed of the revenues of the commonwealth, &c. Yet did not the whole sovereign power reside in the senate, since it could not elect magistrates, make laws, or decide of war or peace; in all which cases the senate was obliged to consult the people.

According to Dr Middleton, the constant and regular supply of the senate was from the annual magistrates; who, by virtue of their several offices, acquired a right to sit and vote in that assembly: the usual gradation of these offices being that of *quæstor*, *tribune* of the people, *ædile*, *prætor*, and *consul*.

The senate always met of course on the first of January, for the inauguration of the new consuls; and in all months universally, there were three days, *viz.* the kalends, nones, and ides, on which it regularly met: but it always met on extraordinary occasions, when called together by consul, tribune, or dictator.

SENATOR, in general, denotes a member of some senate.

SENATUS AUCTORITAS, a vote of the Roman senate, drawn up in the same form with a decree, but without its force, as having been hindered from passing into a decree by some of the tribunes of the people.

SENATUS-CONSULTUM, a decree of the Roman senate, pronounced on some question or point of law; which, when passed, made a part of the Roman law.

SENECIO, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is naked; the pappus is simple; and the calix is cylindrical, and caliculated.

There are 40 species, eight of them natives of Britain.

SENEGA, or **SENEGAL**, a river of Negroland, in Africa, which

which falls into the Atlantic ocean, in 16° N. lat. whence the gum-senega is imported.

SENESCHAL, a term anciently used for steward or major-domo.

SENS, a town of Champagne, in France, situated on the river Yonne, sixty miles south-east of Paris.

SENSATION, in philosophy, the art of perceiving external objects, by means of the senses.

SENSE, a faculty of the soul, whereby it perceives external objects, by means of the impressions they make on certain organs of the body. These organs of sensation are commonly reckoned five, *viz.* the eye, whereby we see objects; the ear, which enables us to hear sounds; the nose, by which we receive the ideas of different smells; the palate, by which we judge of tastes; and the cutis, or skin, which enables us to feel the different forms, hardness, or softness of bodies. See **ANATOMY**, p. 289, 293, 295, 303; **OPTICS**, *passim*; and **PNEUMATICS**.

SENSITIVE PLANT, in botany. See **MIMOSA**.

SENSORIUM COMMUNE, the same with the brain. See **ANATOMY**, p. 285.

SENCE, in Scots law. See **LAW**, Tit. xxxii 1, &c.

SENTENCE, in grammar, a period or set of words, comprehending some perfect sense or sentiment of the mind.

SENTIMENTS, properly signifies the feelings excited in our minds by means of the senses.

SENTINEL, in military affairs, is a private soldier, placed in some post, to watch any approach of the enemy, to prevent surprises, and to stop such as would pass without order, or discovering who they are.

SEPARATION of Husband and Wife, in Scots law. See **LAW**, Tit. vi. 13.

SEPARATISTS, an appellation given to dissenters, from their setting up a separate church from the established one.

SEPIA, in zoology, a genus belonging to the order of vermes mollusca. There are eight brachia interspersed on the interior side, with little, round, serrated cups, by the contraction of which the animal lays fast hold of any thing: Besides these eight arms, it has two tentacula longer than the arms, and frequently pedunculated. The mouth is situate in the centre of the arms; and is horny and hooked, like the bill of a hawk. The eyes are below the tentacula, towards the body of the animal. The body is fleshy, and received into a sheath as far as the breast. There are five species. The officialis, or cuttlefish, emits a black matter when attacked, which hides it from the view of the enemy. The loligo, has a subulated cylindrical body, with a rhomboidal tail. It is sometimes found on the coasts of the frith of Forth, especially after great storms. The other species are mostly found in the Mediterranean sea.

SEPS, in zoology. See **LACERTA**.

SEPTARIÆ, in natural history, a large class of fossils, commonly known by the names of ludus Helmontii and waxen veins.

They are defined to be fossils not inflammable, nor soluble in water; of a moderately firm texture, and dusky hue, divided by several septa or thin partitions, and composed of a sparry matter greatly debased by earth, not giving fire with steel, fermenting with acids, and in great part dissolved by them, and calcining in a moderate fire.

Of this class there are two distinct orders of bodies; and under those, six genera. The septariæ of the first order are those which are usually found in large masses, of a simple uniform construction, but divided by large septa either into larger and more irregular portions, or into smaller and more equal ones, called talc. The genera of this order are four: 1. Those divided by septa of spar, called *ecomæ*. 2. Those divided by septa of earthy matter, called *gastrophragmia*. 3. Those divided by septa of the matter of the pyrites, called *pyntercia*. And 4. Those divided by septa of spar, with an admixture of crystal, called *diagastrophragmia*.

Those of the second order are such as are usually found in smaller masses, of a crusted structure, formed by various incrustations round a central nucleus, and divided by very thin septa. Of this order are only two genera: 1. Those with a short roundish nucleus, inclosed within the body of the mass; And, 2. Those with a long nucleus, standing out beyond the ends of the mass.

SEPTEMBER, the ninth month of the year, consisting of only thirty days: it took its name as being the seventh month, reckoning from March, with which the Romans began their year.

SEPTENTRIO, in astronomy, a constellation more usually called *ursa minor*.

In cosmography, the term *septentrio* denotes the same with north: and hence, *septentrional* is applied to anything belonging to the north, as *septentrional signs*, *parallels*, &c.

SEPTIZON, in Roman antiquity, a celebrated mausoleum, built by Septimus Severus, in the tenth region of the city of Rome: it was so called from *septem* and *zona*, by reason it consisted of seven stories, each of which was surrounded by a row of columns.

SEPTUAGESIMA, in the calendar, denotes the third Sunday before Lent, or before quadragesima Sunday; supposed by some to take its name from its being about seventy days before Easter.

SEPTUAGINT, the name given to a Greek version of the books of the Old Testament. See **BIBLE**.

SEPTUM, in anatomy, an inclosure, or partition, a term applied to several parts of the body which serve to separate one part from another.

SEPULCHRE, a tomb, or place destined for the interment of the dead. This term is chiefly used in speaking of the burying places of the ancients, those of the moderns being usually called *tombs*.

Sepulchres were held sacred and inviolable, and the care taken of them has always been held a religious duty, grounded on the fear of God, and the belief of the soul's immortality. Those who have searched or violated them have been thought odious by all nations, and were always severely punished.

The Egyptians called sepulchres, eternal houses; in contradistinction to their ordinary houses or palaces, which they called *inns*, on account of their short stay in the one, in comparison of their long abode in the other.

Regular canons of St SEPULCHRE, a religious order, formerly instituted at Jerusalem, in honour to the holy sepulchre, or the tomb of Jesus Christ.

Many of these canons were brought from the Holy Land into Europe, particularly into France by Lewis the younger; into Poland, by Jaxa a Polish gentleman. and into

into Flanders, by the counts thereof; many also came into England. This order was however suppressed by pope Innocent VIII. who gave its revenues and effects to that of our Lady of Bethlehem: which also becoming extinct, they were bestowed on the knights of St John of Jerusalem. But the suppression did not take effect in Poland, where they still subsist, as also in several provinces of Germany. These canons follow the rule of St. Augustine.

Knights of the holy SEPULCHRE, a military order, established in Palestine about the year 1114.

The knights of this order in Flanders chose Philip II. king of Spain, for their master in 1558, and afterwards his son; but the grand master of the order of Malta prevailed on the last to resign: and when afterwards the duke of Nevers assumed the same quality in France, the same grand master, by his interest and credit, procured a like renunciation of him, and a confirmation of the union of this order to that of Malta.

SEQUELS, in Scots law. See *LAW*, Tit. xvi. 12.

SEQUESTRATION, in Scots law. See *LAW*, Tit. xix. 10. and xx. 12.

SEQUIN, a gold-coin, struck at Venice, and in several parts of the grand seignor's dominions.

SERAGLIO a Persian word, which signifies the palace of a prince or lord; in which sense the houses of the ambassadors of England, France, &c. are, at Constantinople, called their seraglios. But the term seraglio is used, by way of eminence, for the palace of the grand seignor at Constantinople, where he keeps his court, in which his concubines are lodged, and where the youth are trained up for the principal posts of the empire. It is in form of a triangle, about two miles round, at the end of the promontory Chryfoceras, now called the Seraglio-point: the buildings extend to the top of the hill, and from thence there are gardens that reach to the sea. The outward appearance is not very beautiful, the architecture being irregular, consisting of separate edifices, in the manner of pavilions and domes. The old seraglio is the palace where the grand seignor's old mistresses are kept.

The ladies of the haram, which is the part allotted to the women, is a collection of young beautiful girls, who, on their admission, are committed to the charge of some old lady, and taught musick, dancing, and other accomplishments. These frequently play and dance before the grand seignor while others entertain him with their conversation. Besides these ladies, there are a great many black eunuchs, and female slaves, in the seraglio, whose business it is to guard and wait upon them.

SERAPH, or *SERAPHIM*, a spirit of the highest rank in the hierarchy of angels: who are thus called from their being supposed to be most inflamed with divine love, by their nearer and more immediate attendance at the throne of God, and to communicate their fervour to the remoter and inferior orders.

SERAPHIC, burning or inflamed with love or zeal, like a seraphim: thus St. Bonaventure calls the seraphic doctor, from his abundant zeal and fervour.

SERAPIAS in botany, a genus of the gynandria-diandria class. The nectarium is oval and gibbous, with an oval lip. There are five species; two of them natives of Britain, viz. the latifolia, or broad leaved bastard hellebore; and the lingifolia, or white-flowered bastard hellebore.

SERENADE, a kind of concert given in the night, by a lover to his mistress, under her window. These sometimes only consist of instrumental musick, but at other times voices are added: the musick and song composed for these occasions are also called serenades.

SERENE a title of honour given to several princes, and to the principal magistrates of republics. The king of England, the republic and the doge of Venice, and the children of the king of Spain, are called Most Serene: and when the pope, or the sacred college, write to the emperor, to kings, or the doge, they give them no other title: in like manner the emperor gives no other title to any king, except to the king of France.

SERGE, a woollen stuff manufactured in a loom, of which there are various kinds, denominated either from their different qualities, or from the places where they are wrought; the most considerable of which is the London serge, which is highly valued abroad, and of which a manufacture has been for some years carried on in France.

SERGEANT, or *SERGEANT at law*, or *of the coif*, is the highest degree taken at the common law, as that of doctor is of the civil law; and as these are supposed to be most learned and experienced in the practice of the courts, there is one court appointed for them to plead in by themselves, which is the common-pleas, where the common law of England is most strictly observed; but they are not restrained from pleading in any other court, where the judges, who cannot have that honour till they have taken the degree of serjeant at law, call them brothers.

SERGEANT at arms, or *mace*, an officer appointed to attend the person of the king; to arrest traitors, and such persons of quality as offend; and to attend the lord high steward when sitting in judgment on a traitor.

The number of these officers is by statute limited to that of thirty.

SERGEANT, in war, is an inferior officer in a company of foot, or troop of dragoons, armed with an halbard, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, straiten, and form ranks, files, &c.

SERICUM. See *SILK*.

SERIES, in general, denotes a continued succession of things in the same order, and having the same relation or connection with each other: in this sense we say, a series of emperors, kings, bishops, &c.

SERIES, in mathematicks, is a number of terms, whether of numbers or quantities, increasing or decreasing in a given proportion. See *ALGEBRA*, p. 88.

SERIPHIMUM, in botany, a genus of the syngenesia monogyna class. The calix is imbricated; the corolla consists of one irregular petal; and there is a single oblong seed below the corolla. There are three species, none of them natives of Britain.

SEROSITY, in medicine, denotes an over-abundance of serum.

SERPA, a town of Portugal, in the province of Alentejo, situated on the east-side of the river Guadiana, in W. long. 8° 20', N. lat. 37° 45'.

SERPENS, in astronomy. See *ASTRONOMY*, p. 487.

SERPENT, in zoology. See *COLUMBER*, *BOA*, *ANGUIS*, *CÆCILIA*, *AMPHISBÆNA*, *CROTALUS*.

SERPENTARIA SNAKE-ROOT, the name of a species of aristolochia, or birthwort, with auriculated leaves.

The Virginian snake-root obtained its name, as being accented a specific against venomous bites: but whatever truth there may be in that, it is undoubtedly an excellent diuretic, diaphoretic, and alexipharmic medicine, and consequently good in inflammatory and malignant fevers: it is also a powerful antiseptic, and its dose is from four to ten or fifteen grains in powder.

SERPENTARIUS, in astronomy. See ASTRONOMY, p. 487.

SERPENTINE, in general, denotes any thing that resembles a serpent: hence, the worm or pipe of a still, twisted in a spiral manner, is termed a serpentine worm.

SERRATED, in general, something indented, or notched, in the manner of a saw; a term much used in the description of the leaves of plants.

SERRATULA, in botany, a genus of the syngenesia polygamia æqualis class. The calix is somewhat cylindrical, imbricated, and blunt. There are 16 species three of them natives of Britain, *viz.* the tinctoria, or saw-wort; the alpina, or mountain saw-wort; and the arvensis, or corn saw-wort.

SERRATUS, in anatomy, a name given to several muscles, from their resemblance to a saw. See ANATOMY, Part II.

SERVANT, a term or relation signifying a person who owes and pays a limited obedience for a certain time, to another in quality of master. See LAW, Tit. vii. 34.

SERVETISTS, a name given to the modern antitrinitarians, from their being supposed to be the followers of Michael Servetus, who, in the year 1599, was burnt at Geneva, together with his books.

SERVIA, a province of European Turkey, bounded by the Save and the Danube, on the north; by Bulgaria, on the east; by Albania and Macedonia, on the south; and by Bosnia and Dalmatia, on the west.

SERVICE OF HEIRS, in Scots law. See LAW, Tit. xxvii. 22, &c.

SERVITES, a religious order in the church of Rome, founded about the year 1233, by seven Florentine merchants, who, with the approbation of the bishop of Florence, renounced the world, and lived together in a religious community on mount Senar, two leagues from that city.

SERVITOR, in the university of Oxford, a student who attends on another for his maintenance and learning.

SERVITUDE, in Scots law. See LAW, Tit. xvi. 1, &c.

SERUM, a thin, transparent, saltish liquor, which makes a considerable part in the mafs of blood. See BLOOD.

SESAMOIDAÏSSA, in anatomy. See ANATOMY, p. 188.

SESAMUM, in botany, a genus of the didynamia angiospermia class. The calix consists of five segments; the corolla is campanulated, with five segments; the stigma is lanceolated; and the capsule has four cells. There are two species, both natives of India.

The seeds of this plant, upon expression, yield a larger quantity of oil than almost any other known vegetable; among the Indians, they are used as food.

SESELL, in botany, a genus of the pentandria digynia class. The umbellæ are globular; the involucre consists of many leaves; and the fruit is oval and striated. There are 13 species, only one of them, *viz.* the caruifolia, or meadow-saxifrage, a native of Britain.

SESQUI, a Latin particle, signifying a whole and a half, which joined with *altera, terna, quarta*, &c. is much used in the Italian music to express a kind of ratios, particularly several pieces of triples.

SESSILE, among botanists. See BOTANY, p. 541.

SESSION, in general, denotes each sitting or assembly of a council, &c.

SESSION OF *parliament*, is the season or space from its meeting to its prorogation.

Court of SESSION, in Scots law. See LAW, Tit. iii. 4.

SESTERCE, a silver coin in use among the Romans. Some authors make two kinds of sesterces, the less called *sestertius*, in the masculine gender; and the great one, called *sestertium*, in the neuter; the latter containing a thousand of the other.

Others will have any such distinction of great and little sesterces unknown to the Romans: *Sestertius*, say they, was an adjective, and signified *as sestertius*, or two asses and an half; and when used plurally, as in *quinquaginta sestertium*, *sestertia*, it was only by way of abbreviation, and there was always understood *millia*, or thousand.

SESTOS, a noted fortress of European Turkey, situated at the entrance of the Hellespont or Dardanelles, twenty-four miles south-west of Gallipoli.

SET, or SETS, a term used by the farmers and gardeners to express the young plants of the white thorn and other shrubs, with which they use to raise their quick or quick-set hedge.

SETHIANS, in church-history, christian heretics, so called because they paid divine worship to Seth, whom they looked upon to be Jesus Christ the son of God, but who was made by a third divinity, and substituted in the room of the two families of Abel and Cain, which had been destroyed by the deluge. These heretics appeared in Egypt in the second century; and as they were addicted to all sorts of debauchery, they did not want for followers, and continued in Egypt about two hundred years.

SETON, in surgery, a few horse-hairs, small threads, or large packthread, drawn through the skin, chiefly the neck, by means of a large needle or probe, with a view to restore or preserve health by a discharge of matter.

SETTE, a vessel very common in the Mediterranean, with one deck, and a very long and sharp prow; they carry some two masts, some three, without topmasts. Their yard and sails are all like the mizen; the least of them are of sixty tons burden: they serve to transport cannon and provision for ships of war and the like.

SETTING, in astronomy, the withdrawing a star or planet, or its sinking below the horizon.

SETTING, in the sea language. To set the land or the sun by the compass, is to observe how the land bears on any point of the compass, or on what point of the compass the sun is. Also when two ships sail in sight of one another, to mark on what point the chased bears, is termed setting the chase by the compass.

SETTING, among sportsmen, a term used to express the manner of taking partridges by means of a dog peculiarly trained to that purpose.

SETTLE, a market-town of the west riding of Yorkshire, situated forty-five miles west of York.

SEVENTH, in music, an interval called by the Greeks *heptachordon*. See MUSIC.

SEVE-

- SEVERANCE**, in law, the singling or separating of two or more joined in one writ.
- St. SEVERINO**, a city of Naples, in the province of Calabria, situated east longitude $17^{\circ} 30'$, north lat. $39^{\circ} 16'$. This is also the name of a town in the pope's territories and marquise of Ancona, situated twenty miles south-east of Loretto.
- SEVERN**, a river of South-Britain, which rising in Montgomeryshire, runs east till it enters Shropshire; and having passed by Shrewsbury turns south, and discharges itself into the Bristol channel.
- SEVILLE**, a city of Spain, capital of the province of Andalusia, situated on the river Guadalquivir: in W. long. 6° , N. lat. $37^{\circ} 15'$.
- SEWER**, in the household, an officer who comes in before the meat of a king or noblemen, to place and range it on the table.
- SEWER** is also a passage or gutter made to carry water into the sea or a river, whereby to preserve the land, &c. from inundations and other annoyances.
- SEX**, something in the body which distinguishes male from female.
- SEXAGENARY**, something relating to the number sixty: thus sexagenary or sexagesimal arithmetick, is a method of computation proceeding by sixties. See **ARITHMETICK**, p. 418.
- SEXAGESIMA**, the second Sunday before Lent, or the next to Shrove Sunday, so called as being about the sixtieth day before Easter.
- SEXAGESIMALS**. See **ARITHMETICK**, p. 418.
- SEXTANS**, a sixth part of certain things. The Romans having divided their *as* into twelve ounces, or *uncia*, the sixth part of that, or two ounces, was the sextans. ~ Sextans was also a measure which contained two ounces of liquor, or two cyathi.
- SEXTANT**, in mathematics, denotes the sixth part of a circle, or an arch comprehending sixty degrees.
- The word sextant is more particularly used for an astronomical instrument made like a quadrant, excepting that its limb only comprehends sixty degrees.
- SEXTILE**, the position or aspect of two planets when at sixty degrees distance, or at the distance of two signs from one another.
- SEXTON**, a church-officer, whose business is to take care of the vessels, vestments, &c. belonging to the church, and to attend the minister, church-wardens, &c. at church.
- SEXTUPLE**, in music, denotes a mixed sort of triple which is beaten in double time. See **MUSIC**.
- SEXUALISTÆ**, among botanical writers, those who have established the classes of plants upon the differences of the sexes and parts of fructification in plants. according to the modern method, as Linnaeus, &c. See **BOTANY**, p. 643.
- SEYNE**, a river of France, which rising near Dijon, in Burgundy, runs north-west through Champagne and the isle of France, through Paris, &c. and crossing Normandy falls into the British channel between Havre-de-grace and Honfleur.
- SHAD**, in ichthyology. See **CLUPEA**.
- SHADOW**, in optics, a privation or diminution of light, by the interposition of any opaque body; or it is a plane where the light is either altogether obstructed, or greatly weakened, by the interposition of some opaque body between it and the luminary.
- SHADOW**, in painting, an imitation of a real shadow, effected by gradually heightening and darkening the colours of such figures as by their dispositions cannot receive any direct rays from the luminary that is supposed to enlighten the piece.
- SHAFT of a column**, in building, is the body thereof between the base and capital: so called from its straightness.
- SHAFT**, in mining, is the pit or hollow entrance into the mine.
- SHAFTSBURY**, a borough of Dorsetshire, twenty-five miles north-east of Dorchester; from whence the noble family of Cooper took the title of earl. It sends two members to parliament.
- SHAG**, in ornithology. See **PELICANUS**.
- SHAGREEN**, or **CHAGREEN**, in commerce, a kind of grained-leather, prepared, as is supposed, of the skin of a species of Iqualus, or hound-fish, called the shagreen, or shagrain: and much used in covering cases, books, &c.
- SHAKLES**, in a ship, are the rings with which the ports are shut fast, by lashing the port-bar to them. There also shakles put upon bilbow-bolts, for confining the men who have deserved corporal punishment.
- SHAMBLES**, among miners, a sort of niches, or landing places, left at such distances in the adits of mines, that the shovel-men may conveniently throw up the ore from shamble to shamble, till it comes to the top of the mine.
- SHAMMY**, or **CHAMOIS-LEATHER**, a kind of leather, dressed either in oil, or tanned; and much esteemed for its softness, pliancy, and being capable of bearing soap without hurt.
- The true shammy is prepared of the skin of the chamois-goat. See **CAPRA**.
- SHANK** in the menage, that part of a horse's fore-leg which lies between the knee and the fetlock.
- SHANKER**, or **CHANCER**, in medicine. See **MEDICINE**, p. 132.
- SHANNON**, the largest river in Ireland, which rising in the county of Lestrim, runs southwards, dividing the provinces of Leinster and Connaught; and then turning south-west, runs through the province of Munster; and passing by the city of Limerick, afterwards falls into the western or Atlantic ocean.
- SHARE of a plough**, that part which cuts the ground, the extremity forwards being covered with a sharp-pointed iron, called the point of the share; and the end of the wood behind, the tail of the share. See **AGRICULTURE**, p. 54.
- SHASTIER**, or **SHASTRAM**, a sacred book, containing the religion of the Baniyas: it consists of three tracts; the first of which contains their moral law; the second, the ceremonial; and the third delivers the peculiar observances for each tribe of Indians.
- SHEAT of a plough**, a part passing through the beam, and fastened to the share. See **AGRICULTURE**, p. 54.
- SHEATHING**, in the sea-language, is the casing that part of a ship which is to be under water, with fir board of an inch thick; first laying hair and tar, mixed together, under the boards, and then nailing them on, in order to prevent worms from eating the ship's bottom.
- SHEATS**, in a ship, are ropes bent to the clews of the sails;

fails; serving, in the lower fails, to haul aft the clews of the fail; but, in top-fails, they serve to haul home the clew of the fail close to the yard-arm.

SHEEP, in zoology. See **Ovis**.

SHEERING, in the sea-language. When a ship is not steered steadily, they say the sheers, or goes sheering; or when at anchor she goes in and out, by means of the current of the tide, they also say she sheers.

SHEERS, in a ship, are two masts set across at the upper end of each other; a contrivance generally used for setting or taking out the masts of a ship, where there is no hulk to do that office.

SHEFFIELD, a market-town of Yorkshire, 33 miles south-west of York.

SHEFFORD, a market-town of Bedfordshire, seven miles south-west of Bedford.

SHEFFNEL, a market-town of Shropshire, fourteen miles east of Shrewsbury.

SHEIK, an officer in the mosques of Egypt, whose business is the same with that of the imams of Constantinople.

SHEIK-BELLET, in the Turkish affairs, a magistrate, answering to the mayor of a city with us.

SHEILDS, a port-town of the bishopric of Durham, situated at the mouth of the river Tyne, eight miles east of Newcastle.

SHEKEL, in Jewish antiquity, an ancient coin, worth 2s. 3½d. sterling.

SHELF, among miners, the same with what they otherwise call fast ground, or fast country; being that part of the internal structure of the earth, which they find lying even, and in an orderly manner, and evidently having retained its primitive form and situation.

SHELL, in natural history, a hard, and as it were stony covering, with which certain animals are defended, and thence called shell-fish.

As to the formation of a shell, it is now generally allowed to be formed by a viscous fluid composed of glue, and several sandy particles of an exquisite fineness, which are transmitted through an infinite number of little channels to the pores where it transpires, condenses, and hardens. When the animal increases in bulk, and the extremity of her body is not sufficiently covered, it continues to evacuate and build in the same manner, finishing or repairing her habitation. This viscid matter is proved, by undeniable experiments, to arise from the body of animals, and not from the shell, as some have imagined.

Fossil SHELLS, those found buried at great depths in earth, and often immersed in the hardest stones. These fossil shells, as well as those found lying on the sea-shore, make an excellent manure, especially for cold clayey lands; upon which it does not produce nearly so great an effect for the two first years, as it does in the succeeding ones; the reason of which is, that it is not then sufficiently mixed, but in succeeding time it breaks itself into a number of very small particles, and these all become intimately blended with the molecules of earth, and produce their effect more properly.

SHELTIE, a small but strong kind of horse, so called from Shetland, or Zetland, where they are produced.

SHEPPY, an island at the mouth of the river Medway, making part of the county of Kent.

SHERARDIA, in botany, a genus of plants belonging

to the tetrandria monogynia class. The corolla consists of one funnel-shaped petal; and there are two seeds having three teeth. The species are three, only one of them, viz. the arvensis, or little field-madder, a native of Britain.

SHERBORN, a market-town, twelve miles south-west of York.

SHERBRO, a fort at the mouth of the river Sherbro, in Guinea, formerly in the possession of the English.

SHERENESS, a fort on the north-west part of the isle of Sheppey, located at the mouth of the river Medway, to defend its entrance.

SHERIFF, an officer in each county of England, nominated by the king, invested with a judicial and ministerial power, and who takes place of every nobleman in the county during the time of his office.

SHERIFF, in Scots law. See **LAW**, Tit. iv. 1.

SHEW-BREAD, among the Hebrews, the name given to those loaves of bread which the priests placed every sabbath day upon the golden table in the sanctuary. The shew-bread consisted of twelve loaves, according to the number of the tribes; these were served up hot on the sabbath day, and at the same time the stale ones which had been exposed all the week were taken away. It was not lawful for any one to eat of those loaves but the priests only: this offering was accompanied with salt and frankincense, which was burnt upon the table at the time they set on fresh loaves.

SHIELD an ancient weapon of defence, in the form of a light buckler, borne on the arm, to turn off lances, darts, &c.

SHIELD, in heraldry, the escutcheon or field on which the bearings of coats of arms are placed. See **ESCUTCHEON**.

SHILLING an English silver coin. See **MONEY**.

SHIP, a general name for all large vessels with sails, fit for navigation on the sea; except galleys, which go with oars, and smack sails. See **NAVIGATION**.

A ship is undoubtedly the noblest machine that ever was invented; and consists of so many parts, that it would require a whole volume to describe it minutely. However, we shall endeavour to satisfy the reader the more fully on this head, as it is an article of the utmost importance. And first, to give an idea of the several parts and members of a ship, both external and internal, with their respective names in the sea-language; in Plate CXLV II. is represented a ship of war of the first rate, with rigging, &c. at anchor: Where A is the cat-head; B, the fore-chains; C, the main chains; D, the mizen-chains; E, the entering part; F, the ha'se holes; G, the poop lanterns; H, the che'st-tree; I, the head; K, the stern.

L, The bowprit. 1, 2, Yard and fail. 3, Gammoning. 4, horse. 5, Bob stay. 6, Sprit-fail sheets. 7, Pendants. 8, Braces and pendants. 9, Halliards. 10, Lifts. 11, Clew-lines. 12, Sprit-fail horses. 13, Bunt-lines. 14, Standing lifts. 15, Sprit fail top. 16, Flying jib boom. 17, Flying jib stay and fail. 18, Halliards. 19, Sheets. 20, Ho'se.

M, The sprit-fail top-mast. 21, Shrouds. 22, 23, Yard and fail. 24, Sheet. 25, Lifts. 26, Braces and pendants. 27, Cap. 28, Jack-staff. 29, Truck. 30, Jack flag.

N, The fore-mast. 31, Runner and tackle. 32, 33, Shrouds. 34, Laniards. 35, Stay and laniard. 36, Preventer.

Preventer stay and laniard. 37, Woodling the mast. 38, Yard and sail. 39, Horfes. 40, Top. 41, Crow-foot. 42, Jeers. 43, Yard tackles. 44, Lifts. 45, Braces and pendants. 46, Sheets. 47, Fore tacks. 48, Bow-lines and bridles. 49, Fore bunt-lines. 50, Fore leech lines. 51, Fore top rops. 52, Puttock shrouds.

O, The fore top mast. 53, 54, Shrouds and laniards. 55, Yard and sail. 56, Stay and fail. 57, Runner. 58, Back stays. 59, Halliards. 60, Lifts. 61, Braces and pendants. 62, Horfes. 63, Clew-lines. 64, Bow-lines and bridles. 65, Reef-tackles. 66, Sheets. 67, Bunt-lines. 68, Crofs trees. 69, Cap.

P, The fore top gallant mast. 70, 71, Shrouds and laniards. 72, Yard and sail. 73, Back stays. 74, Stay. 75, Lifts. 76, Clew lines. 77, Braces and pendants. 78, Bow-lines and bridles. 79, Flag staff. 80, Truck. 81, Flag-staff stay. 82, Flag of lord high admiral.

Q, The main mast. 83, 84, Shrouds. 85, Laniards. 86, Runner and tackle. 87, Pendant of the gornet. 88, Guy of ditto. 89, Sail of ditto. 90, Stay. 91, Preventer stay. 92, Stay tackle. 93, Woodling the mast. 94, Jeers. 95, Yard tackles. 96, Lifts. 97, Braces and pendants. 98, Horfes. 99, Sheets. 100, Tacks. 101, Bow-lines and bridles. 102, Crow foot. 103, Top rope. 104, Top. 105, Bunt-lines. 106, Leech-lines. 107, Yard and fail.

R, The main top mast. 108, 109, Shrouds and laniards. 110, Yard and fail. 111, Puttock shrouds. 112, Back stays. 113, Stay. 114, Stay fail and stay halliards. 115, Runners. 116, Halliards. 117, Lifts. 118, Clew-lines. 119, Braces and pendants. 120, Horfes. 121, Sheets. 122, Bow-lines and bridles. 123, Bunt-lines. 124, Reef tackles. 125, Crofs trees. 126, Cap.

S, The main top gallant mast. 127, 128, Shrouds and laniards. 129, Yard and fail. 130, Back stays. 131, Stay. 132, Stay fail and halliards. 133, Lifts. 134, Braces and pendants. 135, Bow-lines and bridles. 136, Clew-lines. 137, Flag staff. 138, Truck. 139, Flag staff stay. 140, Flag stand.

T, The mizzen mast. 141, 142, Shrouds and laniards. 143, Pendants and burtons. 144, Yard and fail. 145, Crow foot. 146, Sheet. 147, Pendant lines. 148, Peck brails. 149, Stay fail. 150, Stay. 151, Derric and spann. 152, Top. 153, Crofs jack yard. 154, Crofs jack lifts. 155, Crofs-jack braces. 156, Crofs jack slings.

V, The mizzen top mast. 157, 158, Shrouds and laniards. 159, Yard and fail. 160, Back stays. 161, Stay. 162, Halliards. 163, Lifts. 164, Braces and pendants. 165, Bow lines and bridles. 166, Sheets. 167, Clew-lines. 168, Stay fail. 169, Crofs trees. 170, Cap. 171, Flag staff. 172, Flag staff stay. 173, Truck. 174, Flag union. 175, Ensign staff. 176, Truck. 177, Ensign. 178, Poop ladder. 179, Bower cable.

Thus we have pointed out the external parts, masts, rigging, &c. an account of all which may be seen under their respective articles MAST, HULL, ROPE, RUDDER, &c.

In Plate CXLIX. is represented the section of a first-VOL. III. N° 93.

rare ship of war, shewing the inside thereof: where A is the head; containing, 1, The stem. 2, The knee of the head, or cut water. 3, The lower and upper check. 4, The tail board. 5, The figure. 6, The gratings. 7, The brackets. 8, The false stem. 9, The breast hooks. 10, The haufe hole. 11, The bulk head, forward. 12, The cat-head. 13, The cat-book. 14, Necessary seats. 15, The manger within board. 16, The bowsprit.

B, Upon the forecattle. 17, The gratings. 18, The partners of the fore mast. 19, The gun wale. 20, The belfry. 21, The funnel for the smoke. 22, The gangway going off the forecattle. 23, The fore-cattle guns.

C In the forecattle. 24, The door of the bulk head, forward. 25, The officers cabins. 26, The first cafe. 27, The fore top fail sheet bits. 28, The beams. 29, The car lines.

D, The middle gun-deck forward. 30, The fore-jeer bits. 31, The oven and furnace of copper. 32, The captain's cook-room. 33, The ladder, or way up into the forecattle.

E The lower gun-deck forward. 34, The knees fore and aft. 35, The spirketings, or the first streak next to each deck; the next under the beams being called clamps. 36, The beams of the middle gun deck, fore and aft. 37, The car-lines of the middle gun-deck, fore and aft. 38, The fore-bits. 39, The after, or main bits. 40, The hatchway to the gunner's and boat-swain's store-rooms. 41, The jeer capston.

F, The orlop. 42, 43, 44, The gunner's, boat-swain's, and carpenter's store-rooms. 45, The beams of the lower gun-deck. 46, 57, The pillars and the riders, fore and aft. 48, The bulk head of the store-rooms.

G, The hold. 49, 50, 51, The foot-hook rider, the floor-rider and the standirt, fore and aft. 52, The pillars. 53, The step of the fore mast. 54, The keelson, or false keel, and dead rising. 55, The dead wood.

H A midships in the hold. 56, The floor timbers. 57, The keel. 58, The well. 59, The chain pump. 60, The step of the main mast. 61, 62, Beams and car lines of the orlop, fore and aft.

I, The orlop a-midships. 63, The cable tire. 64, The main hatchway.

K, The lower gun-deck a-midships. 65, The ladder leading up to the middle gun-deck. 66, The lower tire or ports.

L, The middle gun-deck a-midships. 67, The middle tire ports. 68, The entering port. 69, The main jeer bits. 70, Twisted pillars or stantions. 71, The capston. 72, The gratings. 73, The ladder leading to the upper deck.

M, The upper gun-deck a-midships. 74, The main top-fail sheet bits. 75, The upper partners of the main mast. 76, The gallows on which spare top-masts, &c. are laid. 77, The fore sheet blocks. 78, The rennets. 79, The gun wale. 80, The upper gratings. 81, The drift brackets. 82, The pifs dale. 83, The capston pall.

N, Aft the main mast. 84, The gang-way off the quarter-deck. 85, The bulkhead of the coach. 86, The stair-case down to the middle gun-deck. 87, The beams

of the upper deck. 88, The gratings about the main-mast. 89, The coach, or council-chamber. 90, The stair-case up to the quarter-deck.

O, The quarter-deck. 91, The beams. 92, The carlines. 93, The partners of the mizzen mast. 94, The gangway up to the poop. 95, The bulk-head of the cud-dy.

P, The poop. 96, The trumpeter's cabin. 97, The taffarel.

Q, The captain-lieutenant's cabin.

R, The cuddy, usually divided for the master and secretary's officers.

S, The state-room, out of which is made the bed-chamber, and other conveniences for the commander in chief. 98, The entrance into the gallery. 99, The bulk-head of the great cabin. 100, The stern-lights and after galleries.

T, The ward-room, allotted for the lieutenants and land-officers. 101, The lower gallery. 102, The steerage and bulk-head of the ward-room. 103, The whip-staff, commanding the tillar. 104, The after stair-case down to the lower gun-deck.

V, Several officers cabins abaft the main-mast, where the soldiers generally keep guard.

W, The gun-room. 105, The tillar commanding the rudder. 106, The rudder. 107, The stern-post. 108, The tillar-transom. 109, The several transoms, viz. 1, 2, 3, 4, 5. 110, The gun-room ports, or stern chase. 111, The bread-room scuttle, out of the gun-room. 112, The main capton. 112, The main capton. 113, The pall of the capton. 114, The partner. 115, The bulk-head of the bread room.

X, The bread-room. Y, The steward's room, where all provisions are weighed and served out. Z, The cock-pit, where are subdivisions for the purser, the surgeon, and his mates.

AA, The platform, or orlop, where provision is made for the wounded in time of service. 116, The hold abaft the main-mast. 117, The step of the mizen mast. 118, The keelson, or false keel. 119, The dead-wood, or riving.

Different kinds of SHIPS. All ships at first were of the same form, whatever uses they were designed for; but the various ends of navigation, some of which were better answered by one form, some by another, soon gave occasion to build and fit out ships, not only different in bigness, but also in their construction and rigging: and as trade gave occasion to the fitting out large fleets of different kinds of merchant-ships; so ships of war became necessary, to preserve them to their just proprietors.

SHIPS OF WAR have three masts, and a bowsprit, and are sailed with square sails; the other parts being as described above, and represented in Plate CXLVIII. They are divided into several orders, called *rates*; that is, their degree or distinction as to magnitude, burden, &c. The rate is usually accounted by the length and breadth of the gun-deck, the number of tons, and the number of men and guns the vessel carries. There are six rates, viz.

A common first-rate man of war has its gun-deck from 159 to 178 feet in length, and from 44 to 51 broad. It contains from 1313 to 2000 tons; has from 706 to 1000 men, and carries from 96 to 100 guns. But one of the most considerable first-rate ships was that built at Woolich

in 1701; the dimensions whereof are as follow: The length, 210 feet; number of guns, 110; number of men, 1250; number of tons, 2300; draught of water, 22 feet; the mainmast in length 54 yards, depth 19; main mast in length 39 feet, in diameter 38 inches; weight of the anchor 82 Cwt. 1 qr. 14 lb; cable in length 200 yards, diameter 22 inches.—The expence of building a common first rate, with guns, tackling, and rigging is computed at 60,000 *l.* sterling.

Second rate ships have their gun-decks from 153 to 165 feet long, and from 41 to 46 broad: they contain from 1086 to 1482 tons; and carry from 524 to 640 men, and from 84 to 90 guns.

Third rates have their gun-decks from 140 to 150 feet in length, from 37 42 feet broad: they contain from 871 to 1262 tons; carry from 389 to 476 men, and from 64 to 80 guns.

Fourth rates are in length on the gun-decks from 118 to 146 feet, and from 29 to 38 broad: they contain from 448 to 915 tons; carry from 226 to 346 men, and from 48 to 60 guns.

Fifth rates have their gun-decks from 100 to 120 feet long, and from 24 to 31 broad: they contain from 259 to 542 tons; and carry from 145 to 190 men, and from 26 to 44 guns.

Sixth rates have their gun-decks from 87 to 95 feet long, and from 22 to 25 broad: they contain from 152 to 256 tons; carry from 40 to 110 men, and from 16 to 24 guns.

It is to be observed, that the new-built ships are much larger, as well as better, than the old ones of the same rate; whence the double numbers all along; the larger of which express the proportions of the new built ships, as the less those of the old ones.

MERCHANT SHIPS are estimated by their burden; that is, by the number of tons they bear, each ton reckoned at 2000 lb weight; this estimate being made by gauging the hold, which is the proper place of loading.

Besides those mentioned above, there are other forms: as, 1. The bilander, (Plate CXLIX. fig. 2.) which has rigging and sails not unlike a hoy, only broader and flatter: bilanders are seldom above twenty-four tons, and can lie nearer the wind than a vessel with cross-sails can do. 2. Bomb-vessels, (*ibid.* fig. 3.) have sometimes three masts, and square sails, as represented; but they are also frequently ketch-fashion, with one mast and a mizen. 3. Brigantines (*ibid.* fig. 4.) are now disused; but had two masts, and square sails. 4. Hag-boats (*ibid.* fig. 5.) are masted and sailed ship-fashion, but are built in the form of the Dutch fly-boat. 5. Hoys (*ibid.* fig. 6.) are fitted with one mast and a sprit-sail; whose yards stand fore and aft like a mizen, so that it can lie near the wind. 6. Hulks (*ibid.* fig. 7.) are generally old ships cut down to the gun-deck, and fitted with a large wheel, for men to go in when careening: it has also several capstons fixed on its deck, for setting ships masts. 7. Ketches (*ibid.* fig. 8.) are fitted with two masts; and their main-mast and top mast stand square as those of ships do, but their fore-mast and jibbs as those of hoys do. 8. Lighters (*ibid.* fig. 9.) are vessels made use of for laying down or shifting the moorings, for bringing ashore or carrying on board ships cables, anchors, &c. 9. Pinks (*ibid.* fig. 10.)

fail with three masts, ship-fashion; but are round sterned, with a small projection above the rudder. 10 Punts (*ibid.* fig. 11.) are built square, and used about the docks for fetching clay and other services as the master shipwright wants them for. 11. Shallop (*ibid.* fig. 12.) is a small light vessel, with only a small main and fore mast, and lugg sails, to haul up and let down on occasion. 12. Sloops (*ibid.* fig. 13.) have only one mast, with shoulder-of-mutton, square, lugg, and smack sails. 13. Smacks (*ibid.* fig. 14.) are transporting vessels, with one mast, and an half sprit-fail. 14. Yachts (*ibid.* fig. 15.) have only one mast, with an half sprit or smack fail, and sometimes ketch-fashion.

The most celebrated ships of antiquity are those of Ptolemy Philopater. One was 280 cubits long, 38 broad, and 48 high, each cubit being 1 English foot $5\frac{1}{2}$ inches, and carried 400 rowers, 400 sailors and 3000 soldiers. Another which the same prince made to sail on the Nile, we are told, was half a stadium long. Yet these were nothing in comparison with Hiero's ship, built under the direction of Archimedes; on the structure whereof Mochion wrote a whole volume. There was wood enough employed in it to make 50 galleys: it had all the variety of apartments of a palace; such as banqueting-rooms, galleries, gardens, fish ponds, stables, mills, baths, and a temple to Venus. It was encompassed with an iron rampart, eight towers, with walls and bulwarks, furnished with machines of war; particularly one, which threw a stone of 300 pounds, or a dart 12 cubits long, the space of half a mile, with many other particulars related by Athenæus.

Construction of SHIPS. Naval architecture may be divided into three principal parts: 1. To give the ship such a figure and proportion as may suit the service she is designed for. 2. To find the true form of all the pieces of timber that shall be necessary to compose such a solid. 3. To make proper accommodations for guns, ammunition, provisions, and apartments for all the officers, and likewise room for the cargo.

As to the first part, the length of the keel, greatest breadth, depth in the hold, height between decks and in the wale, and sometimes the height and breadth of the wing-transom, in ships for the merchants service, are agreed on by contract; and from these dimensions the builder forms a draught suitable to the trade the ship is designed for. The first thing that is generally done, is to lay down the keel, the stem, and stern-post, upon the sheer-plane, or plane supposed to pass through the middle line of the keel, stem, and stern-post, cutting the ship in two halves lengthwise. They next determine the proper station of the mid-ship timber, where a perpendicular is erected, and is generally about two thirds of the keel before the stern-post: on this line the given depth of the hold is set off, from the upper side of the keel; to obtain which point, the thickness of all the timber and plank must be added to the height agreed on. This being fixed, will enable us to determine the upper-height of the extreme or greatest breadth of the ship; which, sometimes, is that very point; and from the same place the lower height of the breadth must be determined. The two main heights of the breadth lines, which nearly unite abaft and afore, are next determined. The height of the breadth-line of the top-timber is next formed; being

limited in the midship by contract, but afore and aft only by the judgment and fancy of the artist. If a square stern is designed, the breadth at the wing-transom is limited, being generally about two thirds of the greatest breadth. The artist next fixes the breadth of the top timber, and then describes the two half-breadth lines. After these are formed the places where the several timbers are fixed: and for forming the midship-frame, radii are assumed at pleasure, till the sweeps are made to please the fancy and judgment of the artist. When this midship-frame is formed, a pattern or mould is made to fit exactly to the curve, and the dead-rising, or water-line; and by this and a hollow mould, all the timbers are formed, as far as the rising line, which is parallel to the lower height of the breadth-line.

We come next to consider the upper-works, or all that is above water, called the dead-work: and here the ship must be narrower, by which means she will strain less by working the guns, and the main-fail will be easier trimmed, as the shrouds spread less than they would otherwise do. But though these advantages are gained by narrowing a ship above water, yet great care must be taken not to narrow her too much, lest there should not be sufficient room upon the upper deck for the guns to recoil. The security of the masts should likewise be considered, which require sufficient breadth to spread the shrouds: though this may be assisted by enlarging the breadth of the channels.

Principal qualities belonging to SHIPS. A ship of war should carry her lower tier of guns four or five feet above water; a ship for the merchants service should stow the cargo well; and both of them should be made to go well, carry a good fail, steer well, and lie-to easily in the sea. 1. To make a ship carry a good fail, Mr Du Hamel recommends a flat floor-timber, and somewhat long, or the lower futtock pretty round; also a straight upper futtock, and the top timber to throw the breadth out aloft; and at any rate, to carry her main-breadth as high as the lower-deck; for if the rigging be well adapted to such a body, and the upper-works heightened as much as possible so as all to concur to lower the centre of gravity, there will be no room to doubt of her carrying a good fail. 2. To make a ship steer well, and answer the least motion of the helm, the fashion-pieces should be well formed, the tuck carried pretty high, and the midship-frame carried pretty forward; also there should be a considerable greater draught of water abaft than afore, a great rake forward, and none abaft, and a snug quarter-deck and fore-castle: all these will make a ship steer well. But to make her feel the least motion of her helm, it will be necessary to regard her masts; for a ship that goes well, will certainly steer well. 3. To make a ship carry her guns well out of the water, is effected by a long floor-timber, and not of great rising, a very full midship-frame, and low tuck, with light upper-works. 4. To make a ship go smoothly through the water, without pitching hard, her keel should be long, her floor long and not rising high afore or aft; the area or space contained in the fore-body should also be duly proportioned to that of the after-body, according to the respective weights they are to carry. 5. To make a ship keep a good wind, she should have a good length by the keel, not too broad, but pretty deep in the hold; which will make her floor-timber

timber short, and rising great. As such a ship will meet with great resistance in the water going over the broad side, and but little when going a-head, she will not fall much to the leeward. Now some ship-builders imagine, that it is impossible to make a ship carry her guns well, carry a good sail, and be a prime sailer at the same time; because it requires a very full bottom to gain the two first qualities, and a sharp-bottomed ship best answers the latter; but when it is considered, that a full ship will carry a great deal more sail than a sharp one, a good artist may lo form the body as to have all these three good qualities united, and likewise steer well; for which purpose, Mr Du Hamel recommends somewhat more in length than has been commonly practised.

SHIPTON, a market-town, twenty-four miles south-east of Worcester.

SHIRE, in geography, signifies the same as county; being originally derived from a Saxon word which signifies *to divide*.

SHIVERS, in the sea language, names given to the little rollers or round wheels of pulleys.

SHOAD, among miners, denotes a train of metalline stones, serving to direct them in the discovery of mines.

SHOAL, in the sea-language, denotes a place where the water is shallow.

SHOE, a covering for the foot, usually made of leather, by the company of cordwainers.

SHOE for an anchor, in a ship, the place for the anchor to rest, and fixed to receive the stock, &c. so as to prevent the sheets, tacks, and other running rigging, from galling, or being entangled with the blocks.

SHORE, a place washed by the sea, or by some large river, Count Marigli divides the sea-shore into three portions: the first of which is that tract of land which the sea just reaches in storms and high tides, but which it never covers; the second part of the shore is that which is covered in high tides and storms, but is dry at other times; and the third is the descent from this, which is always covered with water.

SHOREHAM, a borough and port town of Sussex, twenty-five miles east of Chichester. It sends two members to parliament.

SHORT-HAND WRITING.

AS STENOGRAPHY, or the Art of SHORT-HAND WRITING, when well understood, and rendered familiar by practice, is attended with many valuable consequences, we shall, without attempting to enumerate

the infinite variety of systems that have been published, furnish our readers with that system which appears to be the most easy, beautiful, and expeditious, and at the same time calculated for general use.

P A R T I.

THE Alphabet being the foundation upon which the perfection of the art depends, great care must be taken to establish it in the best manner. All the simple sounds must be represented by the shortest marks possible. We must, therefore, not only reject the complex marks established by custom in our common alphabet, but also those letters themselves whose sounds may always be signified by others; and simple marks must be provided for such simple sounds as are by custom represented by two letters a piece: for which reason, it is necessary to examine the alphabet, and to fix the number of characters, before we proceed to investigate the marks which are to represent them. First, then, let us consider what number of consonants may be requisite. We shall afterwards treat of the vowels, which are to be represented by points or dots.

The consonants, according to our usual reckoning, are, *b, c, d, f, g, h, j, k, l, m, n, p, q, r, s, t, v, w, x, y, z*. But custom differs from nature in inserting the letters *c, q, w, x, y*, and in omitting *sh, zh, th, dh, ch*: for *c* having always either the sound of *k* or *s*, *q* that of *ko*, *w* of *oo*, *x* of *ks*, and *y* of *i*; in an alphabet according to nature none of these could have found a place; and *sh, zh, th, dh, ch*, representing single consonantal sounds as much as *ph* does, whose power is that of *f*, ought all to have been denoted by single characters, as most of them are in the alphabets of other languages.

The natural alphabet, therefore, might have been taken

for our short-hand one, rejecting the superfluous letters *c, q, w, x, y*, and inserting in their stead *sh, zh, th, dh, ch*: but having some marks that were not conveniently applicable to any other purpose, and it being a compendium to represent two letters by a single character, as in the *q* and *x*, and some ease to the reader to retain at the beginning of words the *w* and *y*, to which he has been long accustomed; we shall, totally rejecting the *c*, appropriate distinct marks to denote *q, x, w, y*, when they are initial letters; not scrupling however in other situations, if it prove more convenient, to denote them by *k, ks, oo, and i*, respectively.

Zh never had any particular mark to signify it by; and custom has, for a long period of time, ceased to make any distinction in writing between the *th* and *dh*: and as the adherence to nature in making nice distinctions, where custom has not, would be so far, in this case, from serving any valuable purpose of short-hand, that it would rather, on the contrary, render the learning to write and read it more difficult, we have, in pursuance of our plan, complied with custom in dropping the *zh*, and marking the sounds both of *th* and *dh* by the same character.

S and *z* bear the same relation to each other, that the *th* and *dh* do; and the sound of *z* in our customary way of writing is very frequently expressed by *s*, except in cases when it occurs at the beginning of words, which happen but very seldom. These considerations induce us to secure the great convenience which arises from signifying both *s*

and *z* by one mark. And, for a like reason, we shall make one mark representative both of *f* and *v*. The sense of the place will easily discover, to a man tolerably acquainted with English, which of the two it must there represent; and the reader will be taught, when the characters are appropriated to the consonants, how, in most cases, entirely to remove any little ambiguity that possibly might arise from it. Our alphabet will then consist of the following consonants, *viz.* *b, d, [f v], g, h, j, k, l, m, n, p, q, r, [z], t, w, x, y, ch, sh, th.*

The number of our consonants being thus settled, and the reasons for fixing upon that number being given; the next business must be, to invent as many simple marks, easy to be made and distinguished from each other, as are necessarily required to represent them. They must be simple, if brevity be consulted; and they must be easily distinguishable from each other, to avoid the confusion arising from mistaking one letter for another.

Nature affords us four straight lines, sufficiently distinguishable from each other, by their horizontal, perpendicular, and inclined position, to execute our design by; (see Plate CL. N^o 1.) but it affords only these four. In this scarcity of straight lines, recourse must be had to curved ones for a further supply. The four straight lines bent in the following manner, that is to say, the horizontal upwards and downwards, the perpendicular and inclined ones to the right and left, will each of them furnish two more very good short-hand marks; *ibid.* N^o 2.

The number of marks thus increased still falls short of supplying our wants. The best expedient to remedy this defect, is the addition of a little twirl to the beginning of as many of the foregoing marks as there will be occasion for. It is easily and quickly made, when the marks are formed separately; and the twirled marks are joined to preceding ones in as little time as the plain ones. N^o 3. 4.

A sufficient number of proper marks being thus obtained, it remains that each of them be appropriated to the particular consonant which it is to represent. Easy as this may seem, it is, however, a point of the greatest nicety: and demands, not only the most careful consideration, but also the most assiduous application to continual trials and alterations. A short-hand alphabet may have all its characters simple, easy, and distinguishable, when separately formed; and yet not be a perfect one. To merit that title, it is further requisite, that they be so contrived and adjusted, that all the consonants occurring in any word may be easily, beautifully, and interlinely joined together, betwixt two given parallel lines, without taking off the pen. Experience has taught quick writers even of long-hand, that the joining all the letters of a word together contributes much to dispatch, though they are obliged to make little additional strokes for that purpose.

Let us then consider, to what particular consonant each of our marks is to be appropriated; and begin with the four straight lines.

The first of these lines, *viz.* the horizontal as it goes straight forwards, can never exceed the limits of the given parallels: whatever part it begins from; and therefore; in a short-hand formed for lineal beauty, it must be appropriated to that consonant which, of all others, occurs the oftener, and challenges, of right, the most commodious character for beauty and dispatch. Now the consonant that occurs the most frequently in our language (and perhaps in

most others) is the *s*; which has a property, peculiar to itself, of mixing with other consonants before or after it, without the intervention of a vowel. The plural number of most of our substantives, and the third person singular of our verbs, are formed by it; which must occasion the most frequent repetition of it; so that, being undoubtedly the commonest of all our consonants, it must of necessity be denoted by the horizontal straight line.

The second straight line, or perpendicular, is also a very easy mark, and, separately made, even preferable to the other; but as, in union with others, it may endanger our descending below the line, it must therefore be allotted to a common consonant, and one also that will the least occasion us to run that hazard. Now the *t* has, in fact, these and other properties that entitle it to this perpendicular straight line.

The third straight line, by its peculiar inclination, is adapted to a very easy and convenient joining with other characters; because our customary method of inclining the letters, in common writing, teaches us to form it with equal readiness upwards or downwards; as the keeping the previous or following marks within the prescribed parallels shall require. The consonant, therefore, that claims this character is the *r*, which makes for many of our double consonants (as we call them) and adds any other single one to follow it immediately. The straight line then which slopes downwards to the left, is *r*.

The last line of the four straight ones, by its direction or slope to the right, is awkward to make (and therefore never is made) upwards, like the foregoing, to which it unites the most readily. Its properties, upon trial, suit best with the occurrence of the consonants *f* or *v*.

The twirl being formed to the left hand in these four marks, (N^o 5.) disqualifies them from an easy junction with any preceding consonant. They must then, for that reason, be assigned to such consonants as occur the seldomest in the middle or at the end of words, or to such as may be otherwise signified when they do occur in such situations. Now the *h*, or *j*, are rarely to be met with in the middle of words, unless immediately preceded by some preposition, as *inhabit, reject*, &c. in which case, the reader will be taught hereafter how to write them: and when *x* and *y* are not at the beginning of words, they may be expressed by *kt*, and the dot for the vowel *i* respectively. The properties of these four letters agreeing well with those of the four marks, luckily point out a use for four easy characters, which could not however have been conveniently allotted to any other consonants: and the following appropriation of them, upon trial, is found to be the most commodious. *viz.* the first for *h*, the second for *j*, the third for *x*, and the fourth for *y*.

K is a very common consonant; and the frequency of its occurrence will be much increased by its being made so often representative of the rejected *ch*, and *ch* of *sch* a character, therefore, which is not only easy to be made, but which will also join readily with all the rest, without running either above or below the line, must be appropriated to it. The horizontal straight line, with the additional twirl, will, for these reasons, be the most commodious. But as the distinguishing the *k* and *g*, at the beginning of words especially, will, in some degree, facilitate the reading; the horizontal straight line with the twirl above is made for *k*, with the twirl below for *g*, when they are initial letters.

In all other cases, these two marks are used promiscuously for *k* or *g*, whenever a more easy, beautiful junction may by that means be obtained; the one joining evidently much better with the characters which are written upwards, the other with those downwards.

But to give a detail of all the reasons for the appropriation of each particular mark to each consonant, would prove tedious. Most of them cannot escape the observation of an attentive practitioner as he goes along. It will, therefore, be sufficient to assure the reader, that no pains was spared to adjust the alphabet to the utmost nicety, by such an exact attention to continual trials and amendments as was necessary to ascertain the preference of the disposition of the characters in it to any other that could possibly have been pitched upon amongst that almost infinite variety into which they might have been thrown; and that, if he has the curiosity to make the experiment, he will find, that no change can be made in the allotment of the marks, but what will be attended with considerable disadvantage.

Two marks are allotted to *b*; (see Table of the Alphabet, Plate CL.) The first of these marks is the best when separately formed, but does not join well with the *l* or *r*. For similar reasons, some other of the consonants have more than one mark allotted to them.

One or other of the two marks appointed for *w* is always to be used when it is an initial letter; in other situations we scruple not to express it by a dot in the *o* or *ou* place, writing *pour* for *power*; especially if it joins not well with the preceding consonant, or no great ambiguity arises thereby.

The marks being thus adjusted to the particular consonants which they are to represent, let us see how any precedent, subsequent, or intermediate vowel may be affixed to any of these consonants, as occasion shall require.

In separate letters there is no difficulty, there being five distinguishable places for any given vowel or point, either preceding or following the consonant: reckoning, therefore, the vowels *a, e, i, o, u*, according to the established number and sequence, *a* is to be placed at the beginning of the consonant, *e* at the end of the first quarter, *i* at the end of the second quarter, that is the middle, *o* at the end of the third quarter, and *u* at the end of the consonant itself.

In the perpendicular and inclined letters, the vowels which precede are placed upon the left hand; those which follow, upon the right; because we write from left to right; as for example, *at, et, it, ot, ut; ta, te, ti, to, tu*. N° 6.

In the horizontal letters, the vowels which precede are placed above; those which follow, below; because we write from top to bottom; as, *ar, er, ir, or, ur; fa, fe, fi, fo, fu*. N° 7.

In the semicircular letters, the vowels *a, e, o, u*, are placed upon the left hand, the *i* above when they precede, and the contrary when they follow, agreeably to the two foregoing remarks; as, *am, em, im, om, um; ma, me, mi, mo, mu*. N° 8.

A vowel between two consonants may be referred to either, and therefore seems to have two places: but in letters which form an angle when joined, this is the case of *i* only; for *a* and *e* can only be placed immediately after the first consonant, *o* and *u* only before the last; lest *a* and *e*, if placed before the last, should, in the narrow part of the angle, be confounded with *u* and *o* after the first; as, *sat, ret, rit, rot, rut*. N° 9.

This twofold place of *i* may be of use in distinguishing,

when thought necessary, the short *i* from the long one, by making it short when placed immediately after the first consonant, long when before the second; as *quit, quite*, N° 10.

The great difficulty of learning the true pronunciation of our language, occasioned chiefly by our perplexed, various, and confused way of spelling, has been always matter of much complaint with all foreigners who have attempted to learn it. But this absurd irregularity is by far the most remarkable, in the customary management, or rather mismanagement of the vowels. It is hardly possible to give a rule for them, against which the exceptions will not be almost as numerous as the agreeing instances. How frequently do we put two, nay sometimes three vowels, to express the sound of one only? What, for example, has the *e* and *a* to do in the word *beauty*? The short-hand writer, however, is not embarrassed with any of these difficulties. He, totally disregarding the common way of spelling, is to insert only such letters as are pronounced; and must consequently write the word *beauty* thus, *buty*. But the insertion of more vowels than are necessary to the sound is not the only instance of irregularity to be met with;—there being more than five vowel-sounds in our language; and custom, having allotted only five letters to signify them all by, often makes one vowel express two or three different ones, nay, even diphthongs or combinations of vowels. We therefore, taking the advantage which custom in this case affords us, shall extend the power of our dots or points to the same degree. The fairness and propriety of doing this will more fully appear upon a particular examination of all the vowels in their order.

And first, in common writing, the letter *a* has three powers, viz. that of *a*, of *ai* or *ay*, and of *au* or *aw*; as in the words *father, fable, fall, or amen. able, altar*; which are pronounced all one as if they had been written *fathar, faible, faul, or amen, aible, aultar*: so that we are fairly authorised to extend the power of our vowel or point to the same degree in all other instances.

The vowel *e* sometimes expresses singly the sound that two of them are often made for, as in, *he, me, we*; where its sound is the same as that of two *e*'s, as in *fee, tree, agree, &c.* We are therefore free to use one *e* in this case, whenever it suits our purpose, as well as for *ea, ey, ai, eo*; for of what use is the latter of these vowels in *pea, prey, heifer, people*, but to puzzle children and foreigners?

The same irregularity and confusion is observable in the customary management of the other vowels, *i, o, and u*; they each of them singly expressing several different sounds, which also are denoted at other times by several different combinations of them. The vowel *i*, for instance, when it is short, is sounded in English as *ee*, agreeable to the pronunciation of it in most foreign languages; when long, it has always the sound of a diphthong, or combination of the two vowel-sounds, (which we might express by the open *a* or *au*, and the short *i* or *ee*;) which sound or diphthong is also sometimes expressed by *ai*, as *fill, file, foil, fin, fine, join*.

In like manner, the vowel *o* has several different sounds; as in the words *pol, pole do*: the sound of the *o* in *pole*, is sometimes expressed by *ow*, as *few*; sometimes by *wo*, as *sword*; sometimes by *oa*, as *foal*; its sound in *do*, by *oo*, *wo*, and *ough*, as *too, two, through*.

And lastly, the sound of *u* (which is always really a diphthong,

thong, expressible by the combination of the two vowel sounds *ee* and *oo*) is denoted in a great variety of ways in our common spelling, viz by *u, ue, eu, ew, ieu, iew, ugh, eau, you*; as in the words *tune, due, sew, adieu, view, hugh, beauty, you*. We are therefore certainly at liberty to represent all these by a point, in the place of the vowel *u*; and thus not only all the single vowels, but all the combinations of them, are expressible by the shortest and easiest of all marks, viz. a dot in the place of the vowel of nearest sound.

We will now proceed to examine what further use we can make of these marks or letters for the purposes of short-hand. And as numeral figures exhibit to us a kind of short-hand with which every one is acquainted, an allusion to them will perhaps explain what we have to say hereupon.

Observe, then, the figures by which the words or numbers, one, five, four, six, are expressed in the Roman characters, which are likewise some of those which we make use of; I, V, IV, VI. Here we see the figure I is considered in three different situations, as standing by itself, close before, and close after another figure; and has accordingly three different powers, of numeration, subtraction, and addition. When it stands by itself, its name and power is one; when it is close to, or belongs to another figure, it loses its name, yet retains something relative to its power, by lessening or increasing that other figure by one; and both together concur to signify but one word or number, vulgarly expressed by the single figure of 4 or 6.

To apply this to short-hand; let the same character |, being our letter *t*, have also its three distinct powers, viz.

First, When it stands by itself, let it express the commonest word or particle in our language the initial consonant of which is a *t*: let the name therefore of this character, for instance, be *the*; a word which we have such perpetual occasion to write.

Secondly, When it is placed close before any other characters, let it stand for the commonest preposition, or leading part of a word, that begins with the same consonant; which in this case will be *trans*.

And thirdly, When close at the end of other marks, let it signify the commonest ending or termination, of which the first (or only) consonant likewise is *t*, viz. *ity*.

From this easy and regular alignment of a threefold power or signification to a consonant, a threefold advantage naturally follows. 1st. By allotting to every mark standing by itself, a name, viz. that of the commonest word or particle of which it is the first, we shall have a number of words, one or other of them perpetually occurring, dispatched by the single characters of the alphabet, which otherwise, when single, would stand for nothing.

2^{dly}. The prepositional part of a word being described by its leading consonant in close situation, but unjoined to the following part of it, secures alike the beauty and the brevity of the characters in many cases wherein it could not otherwise be maintained; and also renders arbitrary marks needless and superfluous; there being no sort of occasion for complicated notches where the simple letter determines precisely enough the preposition wanted.

3^{dly}. As it does likewise the termination, by its near approach to the end of characters; when, by the mutual help of each other, they describe a word sufficiently to distinguish it from all others.

Thus, in the instance here alluded to, the same straight

lines, and the same situation of them, by which four different numbers are expressed in numeral short-hand, are those by which we should, in literal short-hand, express occasionally four such words as the letters and similar use of them just hinted at would describe, viz. in the numeral I *one*, V *five*, IV *four*, VI *six*; in the literal I *the*, V *fr*, IV *transfr*, VI *frity*.

For though the initial and final power of a consonant could not, indeed, be expressed in this manner by a bad alphabet, and a piecemeal huddling of its characters up and down, to denote the vowel's places; yet, in a well contrived one, where consonants of shorter words fall easily, by one continued stroke, into each other, a break in those of longer ones may be so descriptive of their initial or final syllables, as often to express the whole with a conciseness which many shorter words may not admit of. Every consonant, then, may denote, according to its single, previous, or final situation, a common word, preposition, or termination.

But the horizontal straight line may be made from the top, middle, or bottom of the said horizontal space, that is, from the place of *a, i, o, u*: since, then, these vowels before an *s* make the three common words *as, is, us*, it may as well stand for them all, in their several places, after this manner, *as, is, us*. N^o 10.

Trans is the only common preposition beginning with *t*: but there are three common ones that begin with *s*, viz. *super, circum*, (or, as we should write it according to nature, *fircum*) and *sub*, which the horizontal straight line may also stand for, at the top, middle, and bottom of the line; *circum* in the middle, because of its first vowel *i*: but if, for the like reason, *super* and *sub* were both written at the bottom, it might occasion an ambiguity; therefore we make *super* over *circum* and *sub* under it, because (in Latin) they signify *over* and *under*.

Again, the commonest termination in our language is *son* or *tion*; in pronunciation, *shon*. There are a thousand words, all in general borrowed from the Latin, which end in this manner, the greatest part of them of common use. Now let the letter *r* be drawn near to the end of any of these words, from the place of the vowel preceding the *son* or *tion*, and it will serve for any three final syllables whatever of the numerous words that afford this termination.

A few instances may suffice; as, *oration, repletion, attrition, promotion, effusion*, N^o 11. And also, when one or more consonants intervene between the vowel and termination *tion* or *son*, they are, by the rule, to be expressed by the *s*, drawn from the vowel's place; as, *attraction, attention, affliction, adoption, eruption*, N^o 12.

All the rest of the consonants are to be considered in the same threefold light, viz. as standing by themselves, as placed close before, or close after other marks; and must, accordingly, have a power of denoting some common word, preposition, or termination, in which that consonant is found. This is the general rule; but in practice there are few prepositions and terminations necessary or useful besides those set down in the alphabetical table. This rule is very convenient in some cases; as where the consonants of which the word is composed join not well together, or cannot be kept within the parallels; for instance, in *behold, inhabit, deposit*, N^o 13. and affords a great contraction in others, as *underwritten, diffinition, direction*, N^o 14. But here it is to be observed, that, in placing the termination, regard

is to be had to the vowel's place with respect to the line, and not to its place after the last consonant, (except that happens to be one or other of the three horizontal characters *s*, *k*, or *g*.) as in the above word *direction*: the *s* is drawn from the *e*'s place in the line, but it is in the *o*'s place with respect to the last consonant *r*, which appears evidently to have begun at the bottom of the line. But when *s*, *k*, or *g*, immediately precede the termination, regard is then to be had to the vowel's place after the letter: as *assumption*, *affection*, (N^o 15. first and second examples.) The plural number of the termination is denoted by adding a little *s*; as *verities*, *distinctions*, (*ibid.* third and fourth examples.)

Before the learner begins to write by the preceding alphabet, it may not be improper to premise a few observations upon the form and respective proportion of the letters, and the ways of joining the curved ones with the most ease and elegance.

First, All the perpendicular and inclined letters (that is, all the letters except *s*, *k*, *q*, *m*, *n*, *ch*, and *g*.) are made to touch two parallel lines, the distance of which is measured by the perpendicular (straight line *t*, as in N^o 16.; but, however, these letters are sometimes, for greater convenience, made of half size, and two of them included between the parallels, as in the seventh and eighth examples, N^o 16.

The letters *m*, *n*, *ch*, and *g*, are femicircles; the diameter of which is the *s*, and their radius or height is rather more than one third part of the *t*.

The letters formed from the three straight lines *t*, *r*, and *f*, are segments of larger circles, whose chords are the letters *t*, *r*, and *f*, respectively.

It must be observed, however, that it is not necessary, nor indeed scarce possible, that these proportions should be exactly kept, especially in quick writing; but they are given here, because the nearer they are kept to, the more beautiful the writing appears.

Secondly, When *m* and *n* are joined together, they are not each of them to be made complete; but a part is to be cut off from each of them; and in the same manner the inclined letters, when joined with *m* or *n*, are not made complete, but, running into one another, lose each a part, as N^o 17. So the rest of the curve line letters, when joined together, are made to run into one another smoothly, avoiding, by this means, that stopping of the pen which the making of any angle necessarily occasions; as for instance *nup* is not written, as in the first example N^o 18. but as in the second, part of the curved line being in common both to the *m* and *p*.

Thirdly, The twirl is always made at the beginning, never at the end of any letter; whenever, therefore, the six last characters (N^o 18.) occur, they must be supposed to have been begun from the bottom of the line.—The general rule is, That all perpendicular and inclined letters are to be begun from the top, and drawn downwards; but in all instances, in which the inclined letters (N^o 19.) will join better with the preceding or following marks if drawn upwards, they must be drawn in that direction, as in these words, N^o 20.

Fourthly, The initial or final vowels (the *e* mute excepted) are generally expressed, and the middle ones omitted, except in cases where there are many words consisting of the same consonants which might be liable to be taken for one another. But all words which have one consonant only (except those in the table of the alphabet, which are

expressed by the letter alone) must always have the proper vowel point expressed, as *by*, *to*, &c. because these little words are, as it were, the keys of the sentences in which they are found.

Fifthly, Few monosyllables beginning with a vowel are immediately followed with either *h* or *w*; for which reason, these characters, having a point before them, denote *ht* and *wt* respectively, with the proper vowel between them; as *hat*, *het*, *hit*, *hot*, *hut*, and *wat*, *wet*, *wit*, *wot*, *wut*, N^o 21.

Sixthly, As the horizontal letters *s*, *k*, *q* and the curved ones *m*, *n*, *ch*, and *g*, may be written at the top, or bottom, or any part of the line, the vowel following them may be expressed by their situation between the parallels; as *fan*, *fun*, *man*, *mun* N^o 22.

Seventhly, The first mark for the *th* in the table, not joining well with the mark for *r*, which, however, is very frequently combined with it; and the other *th*, being, by reason of our customary method of leaning the letters the contrary way in common writing, not so readily made; *t* may be put for *th*, when the adjoining letter is of half size only, as *thr*, *rth*, *thm*, *thn*, *thr*, N^o 23. In other cases, a letter of half size signifies that the adjoining one is to be resolved into two letters as *trr*, in the first example N^o 24.; for here the *r* being twice as long in proportion to the *t* as it ought to have been had only one *r* been designed, shows, that in this case the *r* of double length denotes *rr*; but, in the second example, the last character does not signify *ll*; for it cannot be resolved into *ll*; but it may into *lf*; for if you divide the last character into two halves, the lower is our mark for *f*: in like manner, the third example is *ft*.—When there is no other consonant to be joined to the inclined letters *f* or *r*, the lengthening of them by a greater inclination than usual denotes that they are to be resolved into two letters *rr*, *ff*, or *vv*, *fu*, or *vf*; as in the three first examples, N^o 25. *error*, *five*, *foffee*: but when two *t*'s form a word, as for example the word *taught*, or, as we should spell it, *taut*, this expedient cannot be used, without going either above or below the line, which is not to be done upon any account whatsoever. In this case a little break must be made in the *t*, to show that there are two *t*'s, N^o 25. This must be confessed to be not altogether regular, and conformable to our rules of joining the letters; and, had many instances occurred, their frequency would have furnished a full objection against our alphabet; but on the contrary, the repetition of the *t* forming fewer words than that of the other consonants, was one reason of appropriating the perpendicular line to the *t*, the word *taught* being the only one that often occurs in practice.

Eighthly, In some few instances, where a letter joins not well with the preceding one, as the *g* with any drawn downwards, the *ch* with any upwards, and the *j* with neither; we scruple not to borrow the opposite one, or some other of nearly the same sound, in its stead; writing instead of *voyage*, *voyach*; *figure*, for *figure*; *church*, for *church*; *natchelly*, for *majestly*; N^o 26. And when *n* happens to be at the bottom of the line and is followed by *d*; for the sake of easy joining, we write *p* instead of the *d*, as in the first example N^o 27 *fnp* for *fnnd*; and few words in our language ending in *np*, this can cause little ambiguity.

Ninthly, *Cm* and *cn* occurring very frequently, for the sake of dispatch we shorten the marks for *k* and *q*, when followed by *m* or *n*, as in the third and fifth examples, N^o 27:

N^o 27. These cannot be mistaken for *ch* and *g*, the twirl being on the contrary side.

Tenthly, The first mark, N^o 28. placed close after a word, denotes, that there is one syllable still wanting to complete the word; and *ing* being a very common final syllable, it is often so denoted: as, *being, writing*, No. 28.

Eleventhly, A point standing by itself has a power, as well as the consonant marks, of representing a common word. At the top of the line, it signifies the particle *a*; as, *a man*: in the middle *I*, or eye; as, *I will, his eye*: in the *o*'s place *o*; as, *O Lord*: at the bottom *you*; as, *you will*. N^o 29.

Twelfthly, The common way of writing numbers being very compendious, we generally use it when numbers occur. The comma, as it does not resemble any of our short-hand marks, may always be used; but when a full stop is thought necessary, the small circle after the examples, No. 29. may be used instead of the point.

To these rules it may be proper to add a few observations. In writing words (as before observed) we join all the consonants, that are wanted, together; to which, if they suffice to distinguish a word, it is needless to add any of its vowels. As for instance, to write the word *strife*, we join the four consonants of which it is composed into one continued mark or figure comprised within the due limits, as in N^o 30. first example: for if, without regarding the limits, we should make it as in example second, the letters would be the same indeed but the direction in this, and all similar cases, is evidently more inconvenient. When, therefore, there are different ways of joining the same letters together, we must accustom ourselves to the best, or most lineal. The sameness of the entire figure, as well as that of its composing letters, is worth the writer's while to maintain; and also facilitates mutual reading between the fellow-practisers of the same method. There is a kind of mechanism in the case, by which the attention, being less fatigued with any deviations of unusual appearance, easily apprehends the meaning of that which is more conformable to a standard.

Though the letters *strife* are abundantly descriptive of the word *strife*; yet if any one pleases, he may add the point for the vowel *i*, (as in the example, N^o 30.) to suggest the word to him at first, until he can read it readily without that assistance.

In single words, the chief difficulty is, to unlearn the unatural and perplexed method of spelling to which we have been long habituated. In this word *practice*, for example, the consonant *c* is pronounced as *k* in the first syllable, and as *f* in the second, and the vowel *e* has no pronunciation at all. But, being used to these difficulties, it is now become one to know the word by its true and genuine spelling according to our short-hand alphabet, viz. *praktis*.

It may highly perplex a careless writer of new characters, to decipher the true sense thereof; though it should be easy enough to know it, by a little application and practice. But what child would not sooner learn to read this same sentence, if, after being taught the use of his alphabet, he should have it thus written?—*It ma bili perpleks a karkles riter of nu ka rakters, to desiffer the tru sens thereof; tho it shud be efi enuf to kno it, bi a litt aplikafion and praktis*.

Instead, therefore, of scrupling to return from such customary rules as children are first initiated in, to a more just and alphabetical way of writing short-hand, men may easily

be taught, when ripened into some acquaintance with their mother-tongue, to reverse the liberties perpetually taken in long-hand: that is, instead of employing more letters than are precisely necessary to express the sound of words, they may make use of fewer, not only dismissing such as are needful to the sound, but such also as may be omitted, and yet leave the sense of the words easily discoverable. If they can tell what is wanting, it is all one as if it was there; the less expression there is, so much the better for the purposes of brevity, which justifies the greatest omissions, provided what is left be intelligible.

And though the omission of the vowels in the middle of words may, for a while at the first, make it difficult for a learner to read even his own writing without hesitation; yet that difficulty will certainly vanish, in proportion as the short-hand marks become familiar to him as it arises, not so much from that omission, as from the strange and unusual appearances which the characters make to his eye, and which, for that reason, do not suggest to him the consonants, for which they stand, so immediately, but that the attention of the mind is necessarily taken up in recollecting them one by one; whereas, did they appear so familiar and well known to him as all to be apprehended in one view, he would soon discover the word, though all the middle vowels were left out. If any one doubts this, he may soon convince himself, by writing in the common long-hand exactly the same letters which he had written before in the short-hand characters: and if he can read it with ease when so transcribed, he may be certain that a little custom will make the reading of short-hand every whit as easy to him.

And now, the way being sufficiently cleared before him, the learner, after he has, by repeated trials, acquired a facility of forming, with tolerable exactness, all the letters of the alphabet separately, and of remembering what particular consonant each of them represents, may proceed to join two or three of the marks together; writing at first only short words, and frequently trying different ways of joining the marks, in order to discover the best, and most elegant. Several of them being formed almost as easily upwards as downwards, he will find it convenient sometimes to begin from the top, sometimes from the bottom of the line, according to the nature of the mark which follows; and when two marks, which admit of being written downwards only, come together, the line must be divided between them, making each of them half the usual depth, as in examples first and second, N^o 31. and, in some very rare instances, he will be forced to make them three deep, as *spud*, (example third;) except he chuses to make use of the expedient of borrowing the *b*, a letter not very different in sound, writing *spud* for *spud*, as in the fourth example.

That the learner may proceed with the greater ease and certainty, we have given specimens of writing according to the above rules, (Plates CLI, CLII.) for his imitation. He ought to make himself fully master of the first specimen, by reading and copying it over and over with great care, until it becomes quite natural and familiar to him, before he proceeds to the second; and he ought in the same manner to make himself thoroughly acquainted with the second, before he proceeds to the third. Thus moving with slow, but sure steps, he will in a very few days find, that every difficulty has disappeared, and that nothing remains but to practise till the habit is acquired. If he has the curiosity to compare the number of strokes and dots in his first speci-

men in short-hand, which is the Lord's prayer, with those used when it is wrote in the common way, he will find, that the former contains only about 150, while the latter con-

tains near six times that number; which shews how much time and labour may be saved, even by the few simple rules already given.

P A R T II.

AN alphabet, formed upon the most just and natural plan, by which, with the help of a few general rules, all the words of the language to which it is particularly adapted, may be easily, neatly, and speedily written, will not be sufficient to satisfy the expectations of an inquisitive reader; who must be sensible, that however complete the alphabet may be, yet many compendious applications of it may be obtained by a proper inquiry into the nature of our language, and the abbreviations which it admits of. He will not be satisfied with being taught only how to express all the letters of a word by the shortest and easiest strokes, but will also require further instruction how to describe intelligibly words and sentences by as few of those strokes as possible. To investigate, from a few things given, many which are omitted, will be found no unpleasant nor unprofitable exercise of the learner's sagacity; and if the few be properly given, the sense of the passage, and a due attention to the idiom of our language, will render the discovery of the omissions more certain, and also less difficult, than the unexperienced can easily imagine.—Without some such rules of abbreviation, one end of short-hand, that of following a speaker, would scarcely be attainable.

Before the invention of the art of printing, the tediousness of writing all the words at full length put the copiers of books upon forming many ways of abbreviating them, as appears in all manuscripts. In those of the New Testament we find many principal words described by their initial and final letters only, with a dash over them. In Latin manuscripts, those terminations, by which the relations of words to one another are in that language usually expressed, were generally omitted: nor was there any need of writing them at length; for the principal word being given, of which the rest were governed in case, gender, and number, any reader who understood that language could easily supply those omissions. Our language, generally expressing those relations by little particles, does not indeed afford that particular mode of abbreviation. Upon a careful examination, however, it will be found capable of furnishing many others as useful and extensive.

But it will be proper, before we proceed further in this art of abbreviation, to advertise the learner, who is apt to be too eager to push forward, not to embarrass himself with it, till, by a competent practice of writing according to the rules laid down in the first part, he is become so well acquainted with the characters, as to be able to write and read them with as much ease as his own common hand. The best way to learn any art is to proceed by degrees, not venturing upon a second step before the first is perfectly mastered. And it is evident, that this method of proceeding is, on this occasion, particularly necessary: for though, in many sentences, the sense, and the particular construction of the words, may plainly enough point out such of them, as are described with unusual brevity; yet how shall an unpractised learner, unable to embrace in one view the words denoted by the preceding and following marks, determine what the intermediate contracted ones must needs be? But,

if he will have patience to abstain from this second part, until he can write readily, and read without hesitation whatever is written, according to the rules of the first, he may rest assured that he will meet with little more difficulty in reading words contracted than he did in those written more at length, provided that the rules of abbreviation be duly attended to. But, if the reader expects that we are to give him every particular manner of abbreviation which can possibly be invented, he will be disappointed. The principal and most useful rules are given; and it is left to the sagacity of the practiser, by observing the nature of these, and proceeding upon the same principles, to make such further advances as his occasions may require. It would be vain to pretend to have exhausted a subject which is as extensive as the language itself in which we write; and consequently may be carried further and further by every one, in proportion to his skill in the language, and his knowledge of the subject treated upon.

The learner has been already taught how to write all the consonants of any word by one continued mark, those words only excepted which may be more briefly described by the help of prepositions and terminations. He may now advance a step further, and join together such short words as are either represented by the letters of the alphabet alone; or such as, by their frequent occurrence, are become so familiar, as to be readily known, though denoted by their first consonants only. This will be found a greater saving of time than can easily be imagined; and must therefore, when dispatch is required, be done in all instances in which they may be joined neatly and without ambiguity.

RULE I. The different times and modes of the verbs are generally expressed, in the English language, by the help of other verbs, for that reason called auxiliary; as, *will, shall, have, had, can, could, may, must, be, &c.* These must, upon that account, occur very frequently; and, being signified by their first consonant, they may be joined to one another; as, *can be, will be, have or has been, to be, ought to be, must be*, Plate CLIII. N^o 1. and when the negative particle *not* intervenes, it may be denoted by its first consonant, and be joined with them; as, *cannot be*, N^o 2. *will not be, have not been, not to be, ought not to be*, N^o 3. When these joinings are, by a little practice, become easy to the learner, he may proceed further, and join the preceding pronouns to these auxiliary verbs; as, *he must be, he cannot be*, N^o 4. This occasion no ambiguity: for though he was taught in his alphabet, that these two marks (N^o 5.) denoted the former *have*, and the latter *had*; yet, when placed immediately before *must* and *can*, their situation shows that they cannot, in that case, signify *have* and *had*, those auxiliaries never admitting of such an arrangement. And further, as *w* and *h* are often dropped in common speech and writing, as *he'll for he will, we've for we have*; so they may, for the sake of joining, be omitted in short-hand; as, *he will, he will not be, they have been*. N^o 6.

RULE II. The learner was taught in the first part, That in

in writing all the consonants of which any word was composed, the beginnings of the marks which follow must always be joined to the ends of those which precede them: Whenever, therefore, they are joined in any other manner, it is to denote, that each particular mark signifies a whole word, and not a single letter: as for example, the particular way of joining the letters in the first example, N^o 7. is a sufficient indication that they were not intended to represent a word consisting of those two consonants, but two words: and the *n* in the middle of the line standing for *in*, and the *t* for *the*, in the may be written as in that example. So again, the second example, N^o 7. denotes two words; and the *s* being drawn from the place of the vowel *i*, shows the latter of them to be *is*: and though the straight perpendicular line usually represents the article *the*, yet, in that situation, it cannot possibly do so; for that article can never come immediately before a verb, but the pronouns very frequently do. *It* is may therefore be very commodiously written as in that second example; and *it is not to be*, as *it is*, since *it* may be written as in N^o 8. and by dropping *us*, as before, we may write *it's*, for *it was*, *it was not to be*, *it's to be*, for *it were to be*: *it seems to be*; as in N^o 9. for the *s* being drawn from the place of *e*, shows that it must be either *it is*—*to be*, or *it se*—*to be*; and *it seems to be* is so very common a phrase, that it will not give much trouble to the reader, though written in this concise manner.

RULE III. Points being the shortest of all marks, it would argue a great want of economy, as well as invention, not to make all the use of them that can be made consistently with the regularity of our system. The power of representing prepositions and terminations, which was allotted to the consonant marks, could not be given to the points: for, in that situation, they stand for the vowels; and all the distinguishable places, both before and after the consonant marks, are already taken up by the five vowels: but a point placed directly over or under the beginning or end of any of those marks, has as yet had no signification annexed to it. As for instance, in the second example, N^o 10. the point being so placed, that if the *t* was produced, it would pass through it, is very distinguishable from all the vowels. All derivative substantives may therefore be very conveniently represented by making the point stand for the substantive derived from the word at the end of which it is placed; as the two examples, N^o 10. signify *forget*, *forgetfulness*.—But as there are derivative adjectives and adverbs as well as substantives, it will be a great compendium to represent them also by points, distinguishable, by their situation, both from the substantive and the vowel points; which may be done by placing them in a line, which, if produced, would pass through the substantive point, and would also be perpendicular to the last consonant mark; and by making one placed before the substantive-point to signify the adjective, one after it to signify the adverb: As, *forgetful*, *forgetfulness*, *forgetfully*, N^o 11.; *reasonable*, *reasonableness*, *reasonably*, N^o 12.; *sufficient*, *sufficiency*, *sufficiently*, N^o 13.

RULE IV. Although the above described mode of abbreviation is very extensive, there being in our language a great number of long words derived from short ones; yet it is far from being the only use which may be made of these adjective, substantive, and adverb points. In all discourses whatever, there must be some principal words, which, ei-

ther by their more particular relation to the subject, or frequent occurrence, will be easily discoverable, however concisely written. If such words begin with a consonant, the first letter; if not the first vowel and consonant, with the adjective, substantive, or adverb point annexed, will suggest them immediately; and therefore will be, though a brief, yet a sufficient description of them. As for instance, if the following passage be transcribed out of a discourse upon the folly of worldly-mindedness, in common long-hand, after this manner, *Our blessed L—, born by his preaching and ex—, has fully shown us the vanity and folly of seeking for solid and lasting — in the possession of any of the goods of this present w—; every one must immediately see, that the words, described by their initial letters, are too plainly pointed out by the nature of the subject, and their accompanying epithets, to leave any room for doubt or mistake. In following a speaker, the same description of them in short-hand must therefore be allowed to be sufficient. But it may not be amiss to give another instance or two, with the short-hand characters for the abbreviated words; as, *Life and IMMORTALITY are brought to light by the GOSPEL*; or again, *The RESURRECTION of the dead, and a future state of REWARDS and PUNISHMENTS, are plainly and positively taught in the gospel*. In these instances, *immortality gospel, resurrection, rewards, and punishments*, may be wrote as in N^o 14. So in writing after pleaders, who frequently use the expression *with submission to your Lordship*, the words *submission* and *Lordship* may be wrote as in the first and second examples, N^o 15. and if the adjective *humble* be joined to *submission*, it may be denoted by its first consonant, and be joined to the substantive; and the words *humble submission* may be written as in the third example. This will be found a very useful compendium; for there are many substantives to which some particular adjectives are usually joined; as, *human nature, Christian religion, natural philosophy*, &c. Whenever, therefore, the subject treated of will lead to the discovery of the substantive, though denoted only by its first consonant, it will, at the same time, discover the adjoined adjective. This method may indeed appear, at first sight, to clash with the rule about derivative substantives; but it will seldom happen that the two consonants will compose any word from which another can be derived; or if it should, it would scarcely ever be such a one as would agree with the context.*

It will appear evidently, upon a little consideration of the nature of this mode of abbreviation, that no limits can be set to it, but that it may be more or less frequently used, in proportion to the knowledge, skill, and readiness of the writer, which will enable him to judge in what instances such liberties may be taken without occasioning ambiguity. And every writer may accustom himself to mark such words as most frequently occur in his own particular profession, by the initial letters, with the substantive, adjective, and adverb points respectively, which, through custom, will easily suggest those words to him at first sight. But it must not be understood that those marks necessarily imply those words, and no other: They may stand for any other beginning with the same letters, which the sense of the passages requires. It cannot therefore be expected that a list of them should be given here; but the following are some of those which are most commonly used: as, *God, happiness, heaven, Lord, always*, N^o 16.; *altogether, occasion, accordingly*, N^o 17.; *notwithstanding, opinion, perhaps, religion*,

religion, N° 18.; subject, together, world, N° 19.

RULE V. An attention to that property of the English language, of expelling the different connections, and relations of one thing to another, for the most part, by prepositions, which the Greek and Latin, and some modern languages, do by varying the terminations of the substantives, will point out a further application of the dot to the purposes of abbreviation: for as, in the Latin manuscripts, the root or body of the word being given, there was no necessity of writing the various terminations of the cases, since any reader who understood that language could himself supply the particular termination which the case required; so, in English, if the two related substantives be such as may be readily known, even when represented by their first consonants only, they may be joined together, placing a dot at the point of their junction, to show that they are both substantives; and the preposition connecting them may be omitted, for it may as certainly and as readily be supplied by the reader as the cases in Latin before mentioned. This consideration will therefore dictate the following rule, viz. That a dot placed at the point of concurrence of two consonant marks, as in N° 20. denotes two substantives, of which those marks are the first consonants; and also that the latter is governed of, or connected to, the former, by some preposition which is omitted.

As for example, in this sentence, *The sum or substance of all the commandments is contained in the two following, viz. the LOVE of God, and the love of our neighbour*: the words *love of God* may be wrote as in the last example: for as the particular situation of the dot denotes that both *L* and *G* are substantives, the article *the* before the first points out plainly enough the omitted preposition of; and the least degree of attention to the words which precede and follow the contracted mark will discover that it must be the *love of God*.

Or again, *The LOVE OF MONEY is the root of all evil; or, Seek ye first the KINGDOM OF GOD, and his righteousness*: these words *love of money*, and these other words *kingdom of God*, may be wrote as in N° 21.

The articles *a* or *the*, in this and in many of the following ways of abbreviation, may, for the sake of joining, be omitted, as in the following sentence, *Since the light of the gospel has shone upon the world, &c. the light of the gospel may be written as in N° 20.*

And further, though an adjective should precede either of the substantives, yet they may all three be represented by their first consonants joined together, with the dot always placed at the end of the first substantive. No difficulty can ever arise in distinguishing the adjective from the substantives. For, in the following sentence, *The great goodness of God is manifest in all his dealings with his creatures*; if these words, *great goodness of God*, be written as in N° 22. the dot placed at the end of the second mark shows that it must be the first substantive, the third must therefore denote the latter substantive, and the first consequently the adjective. In like manner, in the following sentence, *His Majesty the King of Great Britain*, the words *King of Great Britain* may be wrote as in the first example, N° 23. for the dot being placed at the end of the first mark, it is evident that the first must be a substantive; and a little attention to the usual arrangement of words in the English language suggests that the second must be an adjective, as adjectives generally precede the substantives to which they are related: there is therefore as much given as if it had been written in long-

hand thus, *His Majesty, the K— of G— B—*; which, in a discourse concerning him, would be sufficient to discover that the contracted words must be *King of Great Britain*.

If each of the substantives have an adjective joined to them, there can be no difficulty, for the first and third must be adjectives, except in some rare instances in which the common order is sometimes changed, and the last adjective is put after its substantive, as in this, *the great goodness of God Almighty*: in such cases, either the last adjective must be separated from the rest of the mark; or, if joined, it must have the adjective dot annexed; and *the great goodness of God Almighty* may be written as in the second example, N° 23.

This relation of substantives, which is expressed in Latin by the genitive case, in English by the preposition *of*, is by far the most common: but the rule is more extensive, and serves to express two substantives connected by any preposition whatsoever, as *for*, *in*, *with*, *after*, &c. provided that the context, or any particular words of the sentence, easily indicate not only the two substantives which are denoted by their first consonants, but also the preposition which ought to be inserted. As, for example, in this sentence, *Happy is it for us, if, convinced by experience of the vanity of putting our trust in man, we place all our confidence in God*, the three last words may be expressed as in the first example, N° 24. For the context plainly points out the two substantives; and the verb *place* marks evidently, that the omitted preposition cannot be *of*, but must be *in*.

In this sentence, *Our holy religion absolutely forbids all instances of revenge, our Saviour expressly commanding his disciples to return good for evil*;—*good for evil* may be written as in the second example; for the verb *return* shows plainly that it cannot be *good of evil*, but must be *good for evil*. It may, perhaps, be objected here, that *v* is not the first letter of the word *evil*: but it must be observed, that the words of the rule are That the dot denotes two substantives, of which those marks are the first consonants, not the first letters; and a word may sometimes be so pointed out by others which accompany it, as to be easily discoverable, though the initial vowel be omitted.

It may not be improper to add another example or two for the better understanding of this rule; as thus, *In this present state there is no such thing to be met with as pure unmixed pleasure or pain good or evil; hereb. low all things are mixed, pleasure with pain, good with evil*. The latter part of the sentence, *pleasure with pain, good with evil*, may be wrote as in the two first marks N° 25. for the word *mixed* requiring the preposition *with* after it, shows, that it cannot be *p— of p—*, *g— of v—*, but must be *p— with p—*, *g— with v—*.

Or, *He is now become quite blind, he cannot even distinguish light from darkness*. The last three words may be wrote as in the third mark, N° 25.

Or again, *If we consider, that without health we cannot enjoy any of those pleasures which riches can procure; what man, that estimates things according to their reality, rather than their appearance, would not prefer HEALTH to RICHES: or thus, if he had it in his option, would not rather chuse HEALTH THAN RICHES: or, would not chuse HEALTH BEFORE RICHES*. The three several expressions will be easily distinguished, though wrote all in the same manner, N° 26.

RULE VI. The substantive point, placed before a single consonant

consonant mark, denotes, that the substantive represented by it is to be repeated, with some intervening preposition, as *after, to, by*; as for example, *day after day, time to time*, N° 27.

RULE VII. The substantive, adjective, or adverb point, placed before two or more consonant marks joined together, denotes two or more substantives, adjectives, or adverbs respectively, of which those marks are the first consonants, and also that they are connected by a conjunction.

As for example, *Our blessed LORD and SAVIOUR Jesus Christ, by his DEATH and PASSION, made a sufficient SATISFACTION and ATONEMENT for the sins of the whole world;—Lord and Saviour, death and passion, satisfaction and atonement*, being wrote as in N° 28.

Or further, *The precepts both of NATURAL and REVEALED religion forbid us to do our neighbours any injury*; example first, N° 29. Here the point shows, that both *n* and *r* are adjectives; and the word *religion*, to which they are connected, will immediately suggest the words *natural* and *revealed*.

Or, to add one other instance, *What doth the Lord thy God require of thee but to live SOBERLY, RIGHTEOUSLY, AND GODLY, in this present world?* example second, N° 29. Here it appears, by the prefixed point, that *s, r, and g*, must all be adverbs, and consequently that there is nearly as much expressed as if the same sentence had been written in long-hand after this manner, viz. *What doth the Lord thy God require of thee, but to live s—ly, r—ly, and g—ly in this present world?* which surely would give very little trouble to fill up with the words *soberly, righteously, and godly*.

Thus any series of substantives, adjectives, or adverbs, may be expressed by their first consonants joined together with the proper point prefixed. But we must not indulge ourselves in doing this at all adventures. It is only to be done in such instances, wherein the commonness of the phrase, or the nature of the subject, points out the words signified by those letters; or when the words, so briefly described, are such, that no other can be inserted in their stead consistently with the sense of the passage.

When great dispatch is required, as in the case of following a speaker, all omissions are allowable, which can afterwards be supplied by a careful attention to the idiom of the language, and to the connection of the contracted words with those which precede or follow them. And it may not be improper to observe, that greater or less liberties of contracting may be taken, in proportion as the speaker is more or less accurate in his language. For it is certain, that any contractions, where the style is clear and regular, may be more easily decyphered, than where it is confused and embarrassed. It may happen, indeed, sometimes, that the words signified by such contractions will not occur at first sight: but a little thought will discover them; and the reader will find, that an attention of this sort will very agreeably and infensibly lead him into a more perfect knowledge of the idiom of his own language.

RULE VIII. Many long words may be, and frequently are, expressed in common writing by their first syllable only, with a mark to shew that something is wanting, as *mult—* for *multitude*, *cor—* for *correspondence*. So in short-hand, long words, especially those in which the marks for

the consonants will not join neatly, may be denoted by their first syllable, with as many points annexed as there are syllables wanting; as, *multitude, correspondence* &c. N° 30. And when great dispatch is required, the points may be omitted, especially if the words do not begin with prepositions; as, *signification, difficulty, negligence*, N° 31.

RULE IX. The power given to the consonant marks of representing prepositions and terminations, will enable us to write great numbers of long words after a very expeditious manner: for words beginning with prepositions may be denoted by their respective prepositions, together with the next consonant and vowel; and oftentimes with the next consonant only, adding to it the substantive, adjective, or adverb point, when necessary. As for instance, the first example, N° 32. expresses a word beginning with the two syllables *de-li*; and though there are many words which begin with those syllables, as *deliberate, deliver, delicious*, &c. yet if such a sentence as the following were to be written then, *He was not hasty in his resolution, but took time to deliberate about it*, the word *deliberate* would immediately occur to every one.

The trouble of inserting the vowel may, in many instances, be saved, by beginning the consonant from that point after the preposition in which that vowel should be placed; as in example second, N° 32. the *m* beginning from the *u*'s place after the *t* shows, that the next vowel after *m* is *u*; and the mark therefore is equivalent to *transmu—*, which is a sufficient description of the word *transmutation*.

A few examples more will sufficiently explain this rule: as, *recommend, recommendation, recommendatory*, N° 33. *refignation, resolution, consanguinity*, N° 34. *conveniently, superficially*, N° 35.

The participles may be abbreviated after the same manner, by adding, instead of the points, the termination *ing* or *ed* to the latter consonant mark; as *confi—ing* for *considering*, *confi—ed* for *considered*, N° 36.

Words beginning with double or treble prepositions may be written after the same manner; as, *misinformation, representation, misrepresentation*, N° 37. *incomprehensibility*, example first, N° 38. The prepositions must always be joined together; and, if two consonants begin the next syllable, the writing of them both will help to discover the remainder of the word; as *misunderstanding*, example second, N° 38.

It must appear plainly to every one, upon the least consideration, that the words in the foregoing instances are abbreviated. There can therefore be no danger of mistaking, for example, the mark N° 39. for some short word, such as *daily, duly*, &c. For, by our rule, the *d* disjoined always signifies the preposition *de*: nor can it be a word consisting of the preposition *de* and the syllable *li* or *ly* only; for, if such a word had occurred, it would have been sooner written by joining the marks together, as N° 40. This way of writing therefore shows, that the word begins with the preposition *de*; that the next syllable is *li*; and that there are some other syllable, or syllables, wanting to complete it. Nor can the consonants in those examples in which the vowels were omitted, be mistaken for terminations; as in this example, N° 41. the *k* cannot be supposed to represent the termination *ical*; since it would be absurd to think of describing any word by its preposition and termination only: for as the

Vol. III. N° 93.

2

7 L

†

same

* When one syllable only is wanting, a point cannot be used to express it; for a point so placed must denote a vowel.

same preposition and termination are common to great numbers of words, they alone can never give a good description of any particular one.

This way of reasoning pursued will lead to the discovery of an easy and short method of denoting the words *self* and *selves*, which so frequently follow the pronouns. For, if a disjoined mark loses its power of representing a termination, by being placed close after a preposition, the — must certainly lose that of representing *from* or *tion*, when placed close after any of the pronouns, since they never admit of such a termination. It must therefore, in that situation, denote only the consonant *s* followed by that vowel from whose place in the line it is drawn; and consequently the words *self* and *selves* may be very commodiously represented by drawing the *s* from the *e*'s place, close after any of the pronouns; as, *myself*, *itself*, *ourselves*, *themselves*, &c. N^o 42. And though the word *own* should intervene, yet *self* or *selves* may still be signified in the same manner; as, *my own self*, *his own self*, &c. N^o 43.

The words *what*, *who*, *when*, *how*, &c. have very often the word *soever* added to them, which may, for a reason similar to the foregoing, be very aptly expressed by the *s* drawn from the place of *e*; as *whatsoever*, *howsoever*, *whomsoever*, &c. N^o 44.

RULE X. In like manner, words ending in any of the terminations marked in the preceding table of the alphabet, may be denoted by their first consonant and vowel, together with the proper mark for its termination; as for example, *ar*—*ry* for *arbitrary*, *op*—*ity* for *opportunity*, *cu*—*ity* for *curiosity*, *lawfulness*, N^o 45.

But it must be carefully observed, that the vowel, whether it precedes or follows the consonant, must never be omitted; otherwise the consonant might be taken for a preposition, and then this rule would interfere with the foregoing: whereas its power of representing a preposition is destroyed by the addition of the vowel, whilst the single disjoined mark, at the end, retains its power of representing a termination. The word is therefore described by its beginning and termination, a vacancy being left in the middle to be supplied by the sagacity of the reader.

RULE XI. It cannot have escaped the observation of any one who has considered the English language with any degree of attention, that words of different significations govern, or require different prepositions; that words, for example, signifying *desire*, *knowledge*, *ignorance*, &c. require the preposition *of*; that other words, importing *mercy*, *compassion*, *dependence*, &c. require the preposition *upon*, &c. Care therefore being taken to write the prepositions plainly, the first consonant only will in many instances be found to be sufficiently descriptive of the words which require those particular prepositions. For although there may be many words which begin with the same consonant; yet all those which do not require that particular preposition, are upon that account immediately excluded; and the remainder is by that means reduced to so few, that it will be easy to select the proper one. In every one of the following sentences (and many more of the like kind might be given) the letter *d* denotes a different word, viz. in *He was very d— of being thought rich*; *You may d— upon my promise*; *I d— from him in opinion*; *He d— long about the choice of a patron, but at last resolved to d— his work to*, &c. &c. and yet, by the help of the discriminating prepositions, the particular word proper to each place is easily discoverable.

A few instances will be sufficient to give the learner a right notion of this method of abbreviation.

For example, in the following sentences; *This belongs to me*; *He made some good observations upon it*; *I want to dispose of my house*; *He agreed with me in opinion*;—the words *belongs*, *observations*, *dispose*, *agreed*, may be written as in N^o 46. And in these sentences, *There was not the least difference between us*; *We must take particular care to guard against such passions as we find ourselves most liable to*; *As for his personal estate, he divided it amongst all his children in equal shares*;—the words *difference*, *guard*, *liable*, and *divided*, may be wrote as in N^o 47.

And it may be further observed, that as few English words end with the syllable *to*, the preposition *to* may for that reason be joined to the preceding word, which was directed to be signified by its first consonant only. For the unfitness of the ending will be a sufficient hint, that the mark represents not one, but two words; and, therefore, *This belongs to me*, may be written as in example first, N^o 48. and *liable to*, *satisfactory to*, and *subject to*, may be wrote as in the second, third, and fourth examples, the — in this last instance being made at the bottom of the line, to show that the vowel following it is *u*. But, if any one finds it difficult to write the *u* upwards, he may, whenever it is necessary, distinguish the two last instances from one another, by inserting the *u*, and write *subject to* as in N^o 49.

Other prepositions, which are denoted in the table of the alphabet by a single consonant, may, in like manner, be joined to the preceding word; as in the example, *He made some good observations upon it*,—*observations upon* may be written as in N^o 50. Nor will there be any great danger of the reader's being puzzled by mistaking such like marks for single words; for it will not often happen that the two consonants of which they are composed will form any word, scarcely ever that they will form such a word as will suit the place and agree with the context. A little custom will therefore soon suggest to the learner, that the two marks must denote two words; the latter of which, being represented in his short-hand alphabet by the latter consonant mark, must for that reason immediately occur to him.

RULE XII. Prepositions generally require after them either a noun, or a pronoun. The pronouns being few in number, and in all languages used as substitutes for nouns, must occur very frequently, and by that means soon become familiar to the learner; the pronoun, for that reason, may be joined to the preposition, without danger of creating any difficulty to the reader.

As for example, in these sentences, *He gave it to me*, *He left it to my*, *to us*, *to you*, *to our*, *to your*, the words *to me*, *to my*, *to us*, *to you*, *to our*, *to your*, may be wrote as in N^o 51. The *h*, *th*, or *wh*, may, for the sake of joining, be dropped in the pronouns, which begin with those letters, as *his*, *this*, *whom*, &c. and we may write *to his* as in example first, N^o 52. and *to this* as in example second; distinguishing, if it ever should be thought necessary, *his* from *this*, by the different situation of the point: *to her* and *to their*, as in example third: for a distinction between them can not be made, as was done in the instance before, by the different placing of the point; but the sense of the passage will easily show which it must be. *To whom*, *to those*. or *to whose*, *to which*, *to each*, may be wrote as in the first four examples, N^o 53. *It was not in my power*; *in my*, as in the

the fifth example. *It was thrown under my feet, He came and dwelt amongst us, You may be depend upon me; the words under my, amongst us, upon me, as in N° 54.*

This rule is not to be restrained to those prepositions only which are denoted in the table of the alphabet by a single consonant, as *among, under, upon, &c.* but may be extended to others, which must in that case be represented by their first consonant, and be joined to the pronoun; as, *he did it with my consent*, writing *with my* as in N° 55. This will occasion no ambiguity, since *we* cannot in this place signify the word *will*; for such a sentence as, *he did it will my consent*, would be neither sense nor grammar. Its situation in the sentence, and connection with the pronominal adjective *my*, plainly mark that it must be some preposition which begins with *w*.

And though several prepositions should begin with the same consonant, yet they may be written in this manner, provided that the preceding or following words be such as will serve to distinguish them, and shew which of them must needs there be meant; as in the following examples: *He came privately and took it away without my knowledge; To stoop to so mean an action was much beneath his dignity; It is beyond my reach. Without my* may be written as *with my*, N° 55, and the words *beneath his, beyond my*, as in N° 56. *Above* may be distinguished from *beyond*, by prefixing the initial vowel. Thus, in the following sentence, *it is above my comprehension, above my* may be wrote as in example first, N° 57, and between them, *before my, behind my*, in these sentences, *They divided it equally between them, He had the impudence to do it before my face, He did it slyly behind my back*, may be wrote as in the three last examples N° 57.

But it is to be noted here, that when the propositions themselves are abbreviated, as in these instances above, they cannot help to explain other words, as they did in those mentioned in the beginning of the 11th Rule, in which they were directed to be written plainly; for it would be very puzzling indeed, if that word, which was to assist in explaining others, wanted explanation itself.

RULE XIII. After the learner has, by a little practice, made the last method of abbreviation familiar to himself, he may venture to combine it with the foregoing, and join the preceding word, the preposition, and pronoun all together; and as he had learned before to write *belongs to*, as in example first, N° 58, and as the last rule taught him to write *to me* as in example second, he may now join them all together, and write *belongs to me, extends to us, agreed with me, depend upon me*, as in N° 59; *objurations upon this*, as in example first, N° 60.; and *rebellion against his, dissensions amongst his*, as in the two following sentences, *He was a notorious traitor and caught in actual rebellion against his Majesty, He was an ill natured man, and always endeavouring to sow dissensions amongst his neighbours*, may be wrote as in N° 60.

When a pronoun, or a preposition and pronoun, follow the verb, and are themselves followed by a preposition and pronominal adjective, they may all be joined together; as, *I congratulated him upon his, &c. I condoled with him upon his*. N° 61

The words *some, any, none, which, each, both, &c.*

followed by a preposition and pronoun, may, agreeably to this rule, be denoted by their first consonants, and be joined to the preposition and pronoun; as, *some of them, any of us, none of them*, N° 62. *both of them, which of them, each of them*, N° 63. The first dot is inferred to distinguish the words from one another which begin with the same consonant; as, *none, any, &c.* The latter dot must never be omitted, as it is the appointed way of writing the pronouns when joined to prepositions; as, *of them*, N° 64.

RULE XIV. After the learner has for some time accustomed himself to the foregoing rule, he may advance a step further, and join the adverbs preceding the verbs, and the substantives following the pronominal adjectives, to the verbs and adjectives respectively, denoting both the adverbs and substantives by their first consonants, or at most by their first consonants and vowels; as, for example, in this sentence, *you may safely depend upon my word, safely depend upon my word* may stand as in N° 65.

Difficult as this may seem to a beginner, yet habit, and a little reflection upon the nature of our language, will quickly render it easy to him. His own experience will soon convince him, that contractions, when judiciously made, may be more certainly and easily read than the unexperienced are apt to imagine. It may, perhaps, for a while at the first, be a good method to take the contractions to pieces, writing in long-hand exactly what is given in short-hand. The foregoing contraction so transcribed would stand thus, *you may fa—d— upon my w—*. Here the preposition *upon* will soon suggest, that the preceding word, beginning with the consonant *d*, must be *depend*; and the word denoted by its initial letters *fa*, coming betwixt the auxiliary *may*, and the verb *depend*, is by its situation, according to the usual arrangement of words in our language, plainly enough marked to be an adverb; so that it is nearly the same as if it had been written thus, *You may fa—ly depend upon my w—*, which is too plain a description to prove a stumbling-block to any attentive reader.

RULE XV. Many common phrases, formed by a substantive preceded by the prepositions *with, without, in, &c.* and followed by *to, of, &c.* may be very conveniently contracted; as, *with regard, respect, or reference to*, N° 66, example first. *He basely broke his promise, without any regard to his honour; without any regard to his*, as in example second; *in relation to*, as in the third example; *in order to, in consequence, comparison, or consideration of, in obedience to your*, N° 67.; *by reason of his, by virtue of his*, N° 68. (in this last instance, the proportionably little *b* shews, that the mark following it is to be divided into two letters;) *upon account of, in the power of*, N° 69.

RULE XVI. Common adverbial phrases are, in like manner, often denoted by their initial consonants joined together; as, *for the future, at the same time, at present, in this manner*, N° 70.; *in like manner, in a great measure, in the same manner*, N° 71.; *in so much that, so much the more, in the mean time*, N° 72.; *in general, in particular*, N° 73.

And when the proportion of equality is expressed by *se—as, or as—as*, with some one word intervening, they may be all joined together; as, *so much as, as much as*.

* As a substantive must necessarily follow the adjective *my*, there was no occasion to place the point at the end of the word, shew that it was one.

as well as, as long as, as good, or as great as, &c. N^o 74.

RULE XVII. The contractions which in y be made when it is or it was are followed by an adjective, and to or that, are so numerous, that we must content ourselves with giving a few of the most usual; as, it is impossible to, it was unnecessary to, it is contrary to, N^o 75: it is according to, it is observable that, it is evident that, it is not to be supposed that, &c. N^o 76.

The above methods of abbreviation are such as are of most common use and practice: and though they are not many in number, yet they are very extensive in their application; for a sentence can scarce occur in which some one or other of them will not find a place. But yet we are far from pretending to have exhausted the subject. An accurate and assiduous attention to the nature and idiom of our language may suggest others as useful and extensive as these. Proper care being taken to lay a right foundation, the legible ways of contracting will increase, in proportion to the writer's want of them. The more he writes, the more confidently he may venture to write, and yet be able to read his contractions with ease; provided that he builds them upon some known particularity of our language: for which reason we have been more solicitous to explain the grounds of our rules, than curious in the choice, or copious in the number of examples. But that the learner may have all the assistance necessary, we have furnished him with specimens, (Plates CLIII. CLIV. CLV.) where he will find his rules exemplified; and as the last specimen is taken from a book not in every person's possession, we have given the passage in a note*.

But it may not be amiss, before we conclude, to make a

* PROCEEDINGS on an *Habeas Corpus* upon the commitment (by Sir William Turnbul Secretary of State) of Kendale and Roe for High Treason, 31 October 1695.—Sir Bartholomew Shower, for the prisoners, spoke as follows.

Sir Bartholomew Shower. I am of counsel for these two prisoners: and what we desire at present is only that they may be bailed; though perhaps we might prefer to have them discharged, and that upon good reason.

To induce your Lordship to bail them, I must beg your Lordship's pardon, and I hope Mr. Attorney will hold me excused; if I make a question, whether the person committing hath any authority for such a purpose. It is for my clients, who think themselves aggrieved by this imprisonment: and in truth they say, that they are somewhat hardly dealt with in this case; for the information against them is only for being privy to, and assisting the escape of the criminals who were privy to Sir James Montgomery's escape. But this is fact of which the court will not take notice; and therefore I shall confine myself to the return, as it appears before your Lordship.

With submission, I must insist upon it, that a Secretary of State, *quatenus* Secretary, cannot commit for treason or felony: he is not an officer for such a purpose in common parlance. The word *secretary* imports only a writer of letters; or rather clerical for a superior; and, as Spelman explains the word, this is the sense of it, with the addition of secrecy, of privacy; and so is his glossary upon that word. He is not a privy-counsellor, *quatenus* a Secretary: he is a Justice; and though perhaps, in fact, he may be in the commission; yet, unless he hath taken the oath of that office upon a *scdmum*, he cannot act as such; and I have been five or six privy-counsellors at a time appearing at a session of the peace for this county, in the city of the Duke of Bedford's power, as *capitulum rotularum*, to receive the clerk of the peace; and when intimation was made to them of the Justices oath which they had not taken, they refused to vote, and did thereupon withdraw. Here Sir William Turnbul cannot be presumed or intended to be a Justice of the peace; because the commitment by him is as Secretary, and not as Justice; and so is the return: and upon the return the authority by which he commits ought to appear, otherwise the return is vicious; and here doth appear none but that of a Secretary. Now, if the office of Secretary doth not imply and carry in it a power of committing, then this commitment is erroneous.

Our constitution hath distributed the administration of justice, both in criminal and civil causes, into several courts; and hath appointed several officers for several purposes; some for civil, some for criminal matters; and in criminals some to examine and commit, others to obey and carry, others to receive and keep; some to try and execute: each hath his office, and each hath his power; and of those your Lordship will take notice, as also of their several duties and powers; and so do our law-books. But a Secretary is a court-officer of state, not relating to the administration of justice.

You take notice, in our books, of head-boroughs, constables, sheriffs, coroners, ecclesiasticals, and the like: But neither Coke, *Compton*, *Fitzherbert*, *Smith*, or any book which treats of the jurisdiction of courts, the pleas of the crown, or the officers of justice, do ever mention a Secretary of State; rather relate to foreign negotiations than domestic; and if any home-affairs fall under his cognizance, it is rather as an intelligencer than with any relation to criminals, prisons, or gaols, &c. In all the debates about the liberty of the subjects, and wrongful commitments, which were in parliament in 4 Car. 1. or 1641; and amongst all the precedents mentioned there upon each side, which are multitudes; there is

remark or two upon abbreviations in general.—First, that in all the various ways that can be taken of contracting, (that is of describing words by some shorter method than that of writing all the consonants of which they consist,) care must be taken, when the contraction consists of two or more words joined together, that no one word of it be represented by more than one character; and secondly, that the whole mark, by some means or other, if possible, be shown to be a contraction, as it has been generally done in the foregoing pages, either by the insertion of points in the middle of the marks, as N^o 77. (Plate CLIII.) for some of them; (which, when dispatch is required, is never practised to denote vowels in the middle of words; or by the unusual ending of the mark, as N^o 78. for *liable to*, appears that; for few words (since the termination *eth*, so frequent in scripture-language, is now almost grown obsolete) end in *th*; or by the usual joining of the marks, as, in *the*, it is, &c. N^o 77. Otherwise the reader might be puzzled in hunting for some one word consisting of the letters which are written: whereas, if he knows it to be a contraction, he is not bewildered in his searches, but is at first directed the right road, and has nothing to do but to search after some word for every character, which will suit the description, and agree with the context.

And when contractions are judiciously made, the learner, provided he will observe the caution already given, (and which cannot be too often repeated,) of beginning with the easiest, and of not proceeding to a second, until the first is become familiar, will certainly find the difficulty of deciphering them lessen every day.

But, supposing that there was more difficulty in the read-

ing none by a Secretary. It is true, there are divers per *mandatum Dom. Regii*, by warrant from the Lords of the council. I have perused Dr. Franklin's Annals of King James the 1st. fol. 261. and *Rubricatio*, Vol. 1. 438. and can find none by a warrant from a Secretary. And I have seen an *Edictum* against a person upon that subject, but find nothing of the Secretary's commitment. And it seems very strange, if such a power were lodged in this state-officer, that there should be no precedents for it in those times, when extrajudicial and general warrants were so frequent, and such a violence to the people, and such a stain as it has laid the foundation for the *actio in rebus*.

I shall not controvert the power of the council at present, because it doth not concern the present question: All that I can observe in the case is, that it did begin to be practised in Sir Lionel Jenkyn's time; and yet, even in 1675, when the Popish plot had increased the number of prisoners to a wonderful degree, it is not only known that the chief Justice Serjeants was frequently and often sent for to Whitehall, to examine, and commit, and grant warrants. And sometimes since the secretaries of state have thrown that burden off from themselves upon their secretaries under them, who have been sworn Justices of the peace; and Mr. Bridgeman hath accordingly executed the office of a Justice of peace at Whitehall, and that frequently. It hath been a question, whether a Chancellor, or keeper of the great seal, can commit; and the better opinion hath been, that he cannot: And it seems to be agreed by *Granville*, and other cases *Mor's* Reports, 539. &c. that his commitment is illegal, unless for a cause within his jurisdiction as a court of equity; and the matters must not appear. I must agree, that any man may apprehend another for felony or treason; but there is a vast difference between an arresting a *felon*, or *treasoner* upon suspicion or knowledge, and a formal commitment to prison with a charge of treason. And I am sure Mr. Attorney General will not insist upon this reason; for then the consequence will be, that any man may commit, as well as a Secretary. And I suppose that doctrine will scarce be allowed. I think that any man may, as well as he. The reason of an apprehension upon suspicion, or hue and cry, or the like, is not to detain, but to carry to a court to be judged, as in 3. *Inst.* 34. Then here the greater doth not return the less detestable, because he is guilty or supposed; but because, by virtue of such a warrant, he is committed to his custody.

Besides, the reason of our law is against it; for a Secretary cannot administer an oath. Now the law requires, that no man should be committed by an extrajudicial warrant, unless upon oath. If there be but a suspicion, there ought to be oath of the cause of that suspicion; for the person committing cannot commit upon another's suspicion, unless there be oath of some reasonable cause for it. He cannot take bail for a person accused, he cannot take a recognizance to prosecute. And I may very well challenge any man living to show me any recognizance ever returned into any court, that was taken by a Secretary, either for such a crime, or a criminal, or an offence, or a prosecution, or a crime, or a crime otherwise; for they have often taken bonds to the king with condition to appear here. And your Lordship, and the court, hath often had much trouble in that matter; for, they being bound to appear here, and the practice is always otherwise, because no recognizance returned or taken whereupon to find such an appearance.

Now it seems strange, may affirm, that our constitution, which we admire for its wisdom, should appoint an officer who would commit, and yet cannot give an oath, whereon to found a commitment, that cannot bail, that cannot take any recognizance to prosecute: This is to make the liberty of the subject very precarious, no twelvemonth since the debates and sayings of judges in favour of it, *see STATE TRIALS*, Vol. V. Page 655.

ing of them; yet, provided that they may be certainly made out by due attention to the subject treated upon, and the idiom of the language, it will be sufficient: for the learner must be advertised, that these contractions are not designed to be taught as the common standard method of writing short-hand upon all occasions.—That method which was taught in the first part, and which will be as easily read, upon a little practice, as common long-hand, will be found sufficiently short for all common purposes; and it should therefore be kept to when very great dispatch is not required.

Inventors of short-hand have generally introduced into their systems a multitude of *arbitrary* marks, to signify particular words and phrases, which are often chosen rather upon account of their length than their frequent occurrence. The injudicious application of these arbitrary marks is not

the only objection against them. They are not only burdensome to the memory, and tedious and difficult to be learned, but are forgot even by the writer himself, unless he sits down to decypher immediately whilst every thing is fresh in his memory.

These objections lie not against the above methods of abbreviation. They burden the memory with no new and arbitrary marks, and with but few rules for the extension of the powers of the alphabetical characters; and the rules are so general, and applicable to such a multitude of cases perpetually occurring, that they give this system the advantage, even in point of expedition, over arbitrary marks, and at the same time leave the writing legible, whatever length of time intervenes, not only to the writer himself, but also to every fellow-practiser of the same method.

S I A

SHOT, a denomination given to all sorts of balls for fire-arms: those for cannon being of iron, and those for guns, pistols, &c. of lead.

SHOVELER, in ornithology. See *ANAS*.

SHOULDER BONE, in anatomy. See *ANATOMY*, p. 175.

SHOULDER-BLADE. See *ANATOMY*, p. 176.

SHOWER, in meteorology, a cloud resolved into rain. See *RAIN*.

SHREW MOUSE. See *MUS*.

SHREWSBURY, the county-town of Shropshire, situated on the river Severn: W. long. 2° 46', N. lat. 52° 46'. It sends two members to parliament.

SHRIMP, in ichthyology. See *SQUILLA*.

SHRINE, in ecclesiastical history, a case or box, to hold the relics of some saint.

SHROPSHIRE, a county of England, bounded by Cheshire on the north, by Staffordshire on the east, by Herefordshire on the south, and by Montgomeryshire on the west.

SHROVE TUESDAY is the Tuesday after Quinquagesima Sunday, or the day immediately preceding the first of Lent; being so called from the Saxon word *shrive*, which signifies *to confess*, as having been employed by the people in time of popery, in confessing their sins, in order to receive the sacrament, and thereby qualify themselves for a more religious observation of Lent.

SHROUWS, in a ship, are the great ropes which come down both sides of the masts, and are fastened below to the chains on the ship's side, and aloft to the top of the mast; being parcelled and served in order to prevent the mast's galling them. The top-mast shrouws are fastened to the puttock-plates, by dead eyes and laniards, as the others are.

SHRUB, among naturalists, denotes a dwarf-tree, or a woody plant less than a tree; such are holly, box, privet, &c.

SHUTTLE, in the manufactures, an instrument much used by weavers, in the middle of which is an eye, or cavity, wherein is inclosed the spool with the woof.

SI, in music, a seventh note or sound, added by Le Maire to the six ancient notes invented by Guido Aretine, viz. *ut, re, mi, fa, sol, la, si*.

SIAM, the capital of a kingdom of the same name, in the

S I C

further peninsula of India: E. long. 101°, N. lat. 14°. **SIBA**, a province of the higher India, situated between Tibet on the east, and Lahor on the west.

SIBALDIA, in botany, a genus of the pentandria pentagynia class. The calix consists of ten segments, and the corolla of five petals inserted into the calix; the stamens are placed on the side of the germen; and there are five seeds. The species are two, only one of them viz. the procumbens, or bastard cinquefoil, a native of Britain.

SIBERIA, or **ASIATIC RUSSIA**, the most northern country of Asia, situated between 60° and 130° E. long. and between 47° and 72° N. lat. being upwards of two thousand miles in length from east to west, and one thousand five hundred miles in breadth from north to south. We include the Calmuc Tartars within the limits of Siberia, as they acknowledge themselves subject to the empire of Russia.

SIBTHORPIA, in botany, a genus of the didynamia angiospermia class. The calix consists of five segments, and the corolla of five equal ones; the pairs of stamens are remote; the capsule is compressed, globular, and has two cells, with a transverse dissepimentum.

SIBYLS, in pagan antiquity, certain women said to have been endowed with a prophetic spirit, and to have delivered oracles foretelling the fates and revolutions of kingdoms &c.

The most eminent of the ten sibyls mentioned by ancient writers, was the whom the Romans called the Cumæan or Erythræan sibyl, from her being born at Erythræ in Ionia, and removing from thence to Cumæ in Italy, where she delivered all her oracles from a cave dug out of the main rock, according to Virgil, *Æn.* III. 441, &c.

There is still preserved, in eight books of Greek verses, a collection of verses pretended to have been delivered by the sibyls; but the generality of critics look upon it as spurious: and it is the opinion of Prideaux, that the story of the three books of the sibyls, sold to Tarquin, was a state-trick or fetch of politics.

SICILY, the largest of all the Italian islands, anciently called Trinacria, from its triangular figure: it is situated between 12° and 16° E. long. and between 37° and 39° N. lat. being about one hundred and seventy miles long, and one hundred broad.

It is separated from Calabria, in Italy, by the straits of Messina, which, in the narrowest part, is not seven miles over.

SICYOS, in botany, a genus of the monœcia syngenesia class. The calix and corolla of the male have each five segments; and there are three filaments; the calix and corolla of the female are the same with those of the male; the stylus is trifid; and the drupa contains one seed. There are two species, none of them natives of Britain.

SIDA, in botany, a genus of the monadelphia polyandria class. The calix is simple and angular; the stylus is divided into many parts; and there are many capules, each containing one seed. There are 23 species, none of them natives of Britain.

SIDEREAL YEAR. See **ASTRONOMY**, p. 458.

SIDERIA, in natural history, the name of a genus of crystals, used to express those altered in their figure by particles of iron. These are of a rhomboidal form, and composed only of six planes. Of this genus there are four known species: 1. A colourless, pellucid, and thin one, found in considerable quantities among the iron ores of the forest of Dean in Gloucestershire, and in other the like places. 2. A dull, thick, and brown one, not uncommon in the same places with the former. And, 3. A black and very glossy kind, a fossil of very great beauty, found in the same place with the others, as also in Leicestershire and Sussex.

SIDERITIS, in botany, a genus of the didynamia gymnospermia class. The stamina are within the tube of the corolla; and there is a short stigma over-lying another one. The species are eleven, none of them natives of Britain.

SIDEROXYLUM, in botany, a genus of the pentandria monogynia class. The corolla consists of ten segments alternated crooked inwards; the stigma is simple; and the berry contains five seeds. There are three species, none of them natives of Britain.

SIDMOUTH, a port-town of Devonshire, situated on a bay of the English channel, ten miles south-east of Exeter.

SIDON, or **SAYD**, a port-town of Palestine, in Asiatic Turkey, seventy miles north of Jerusalem. It is still a place of some consideration, being the residence of a Turkish bashaw.

SIDRA, an island of the Archipelago, situated at the entrance of the gulph of Napoli.

SIEGE, in the art of war, the encampment of an army before a fortified place, with a design to take it.

SIENNA, a city of Italy, in the duchy of Tuscany, situated thirty-six miles south of Florence.

SIERRA LEON, a river of Guinea, which falls into the Atlantic ocean, in W. long. 14°, and N. lat. 7°.

SIEUR, a title of respect among the French, like *maître* among us: it is much used by the lawyers, as also by superiors in their letters to inferiors.

SIGAN, a town of China, in the province of Xenfi: E. long. 108°, and N. lat. 34°.

SIGESBECKIA, in botany, a plant of the syngenesia polygamia superflua class. The receptacle is paleaceous; it has no pappus; the involucreum has five leaves; and the radius is dimidiated. There are two species, none of them natives of Britain.

SIGETH, a town of lower Hungary, situated seventy-three

miles south-west of Buda, and subject to the house of Austria. **SIGHT**, or **VISION**. See **OPTICS**.

SIGISTAN, the capital of a province of the same name, in Persia: E. long. 62°, and N. lat. 31°.

SIGN, in general, the mark or character of something absent or invisible.

Among physicians, the term sign denotes some appearance in the human body, which serves to indicate or point out the condition of the patient, with regard to health or diseases.

SIGN, in algebra. See **ALGEBRA**, p. 80.

SIGN, in astronomy. See **ASTRONOMY**, p. 435.

SIGNATURE, a signing of a person's name at the bottom of an act or deed, wrote by his own hand.

SIGNATURE, in Scots law. See **LAW**, Tit. xii. 24.

SIGNATURE, in printing, is a letter put at the bottom of the first page at least, in each sheet, as a direction to the binder in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet: if there be more sheets than letters in the alphabet, to the capital letter is added a small one of the same sort, as A a, B b; which are repeated as often as necessary. In large volumes it is usual to distinguish the number of alphabets after the first three or four, by placing a figure before the signature, as 5 B, 6 B, &c.

SIGNET, one of the king's seals, made use of in sealing his private letters, and all grants that pass by bill signed under his majesty's hand: it is always in the custody of the secretaries of state.

SIGNET, in Scots law. See **LAW**, Tit. iii. 16.

SILENE, in botany, a genus of the decandria trigynia class. The calix is ventricose; the corolla consists of five unguiculated petals; and the capsule has three cells. There are 34 species, 6 of them natives of Britain.

SILESIA, a duchy belonging to the king of Prussia, two hundred miles long, and seventy broad: it is bounded by Brandenburg on the north, by Poland on the east, by Hungary on the south, and by Moravia and Bohemia on the west.

SILESIAN EARTH, in the materia medica, a fine alstringent bole. It is very heavy, of a firm compact texture, and in colour of a brownish yellow. It breaks easily between the fingers, and does not stain the hands; is naturally of a smooth surface, and is readily dissoluble in water, and melts freely into a butter-like substance in the mouth. It leaves no grittyiness between the teeth, and does not ferment with acid menstrua. It is found in the perpendicular fissures of rocks near the gold-mines at Strigonium in Hungary, and is supposed to be impregnated with the sulphur of that metal. It is a good alstringent, and better than most of the boles in use.

SILIQUEA, a term used by botanists to denote a pod.

SILIQUEA. See **BOTANY**, p. 637.

SILK, is properly an animal fluid, hardened by the air; being an extremely soft and glossy thread, spun by the silk-worm, the body of which consists of eleven rings.

The humours found in the body of this insect approach to the nature of silk: since, on being rubbed in the hand, they leave a solid crust behind. In the sides of the belly, all about the ventricle, there are deposited a vast number of vessels, which contain the silky juice: these run with various windings and meanders to the mouth; and are so disposed,

disposed, that the creatures can discharge their contents at pleasure at the mouth; and, according to the nature of the juices that they are supplied with, furnish different sorts of silk from them, all the fluid contents of these vessels hardening in the air into that sort of thread that we find the web or balls of this creature consist of.

As soon as the silk-worm is arrived at the size and strength necessary for beginning his cod, he makes his web; for it is thus they call that slight tissue which is the beginning and ground of this admirable work. This is his first day's employment. On the second he forms his folliculus or ball, and covers himself almost over with silk. The third day he is quite hid; and the following days employs himself in thickening and strengthening his ball; always working from one single end, which he never breaks by his own fault; and which is so fine, and so long, that those who have examined it attentively think they speak within compass, when they affirm, that each ball contains silk enough to reach the length of six English miles.

In ten days time the ball is in its perfection, and is now to be taken down from the branches of the mulberry tree, where the worms have hung it. But this point requires a deal of attention: for there are some worms more lazy than others; and it is very dangerous waiting till they make themselves a passage, which usually happens about the fifteenth day of the month.

The first, finest, and strongest balls are kept for the grain, the rest are carefully wound; or if it is desired to keep them all, or if there be more than can be well wound at once, they lay them for some time in an oven moderately hot, or else expose them for several days successively to the greatest heats of the sun, in order to kill the insect, which, without this precaution, would not fail to open itself a way to go and use those new wings abroad it has acquired within.

Ordinarily, they only wind the more perfect balls; those that are double, or too weak, or too coarse, are laid aside, not as altogether useless, but that, being improper for winding, they are reserved to be drawn out into skeins. The balls are of different colours; the most common are yellow, orange-colour, isabella, and flesh colour; there are some also of a sea-green, others of a sulphur colour, and others white; but there is no necessity for separating the colours and shades to wind them apart, as all the colours are to be lost in the future scouring, and preparing of the silk.

In the philosophical transactions, n^o 252, we find the following observations concerning the goodness of silk, which is best distinguished by its lightness. The organique silk is the best made in the country of Piedmont of any; and two threads are equal in fineness, that is, in smoothness, thickness, and length, for the thread of the first twist. For the second, it matters not whether the single thread be strong before the two are joined, unless to see whether the first twist prove well.

It is necessary that the silk be clean; and it is to be observed, that the straw coloured is generally the lightest, and the white the heaviest of all. The skeins should be even, and all of an equality, which shews that they were wrought together: otherwise we may with justice suspect that it is refuse silk, and cannot be equally drawn out and spun; for one thread will be shorter than the other, which is labour and loss.

It will also be requisite to search the bale more than once, and take from out of the parcels a skein to make an essay; for unless it be known, by trial, what one buys, there is the greatest danger of being cheated in this commodity. To make an estimate, and know the lightness, fix the essay upon one eighth of a portée or hand of silk of a hundred and ten aunes or ells of Lyons in length, and see what it makes of aunes by the eighth part. The skein, which is of eighty threads, must be multiplied by a hundred and ten aunes of Lyons, and from this number must be deducted one eighth: as for example, 110 by 80 makes 8800, the eighth part of which is 1100: and this is the eighth part of a portée, or hand of silk. Now, to calculate what these 1100 aunes weigh, which is the eighth part of a portée, or of 110 aunes of Lyons, it will be proper to take a skein out of the parcels, which you take out from the bale which you judge may contain at least 1100 aunes, to make the one eighth part of a portée; which portée must be divided on two bobbins, half on each; then fix the two bobbins on the centre, or beam, and from thence pass it through the comb hursdissor, viz. 550 from the two bobbins, will make 1100, which will be one eighth part of what you desire to know. This done, you cut off your silk, and carry it to put on the hursdissor: then weigh it, and multiply the weight by eight; it will weigh just as much as a portée of 110 aunes of Lyons, which is the general rule for calculating. When they draw the silk out by this means, one may learn to adjust the weight.

There are silks of Piedmont, which are very light and clean, and are to be preferred before any on the sale: the portée of silk of the lightest weighs near twenty-four penny-weights, and from this it arises in gravity to twenty-five and twenty-six penny-weights the portée, and sometimes to twenty-seven and twenty-eight: but even these weights may be dispensed with, provided that the other qualities be good, that is, that it be well wrought, even and clean. When the silk is more than twenty-eight penny-weights the portée, it must always be proportionably cheaper.

Methods of preparing SILKS. The several preparations which silks undergo to fit them to be used in the manufacture of silken stuffs, are reeling, spinning, mulling, bleaching, and dyeing. To wind silks from off the balls, two machines are necessary: the one a furnace, with its copper; the other a reel, or frame, to draw the silk. The winder, then, seated near the furnace, throws into the copper of water over the furnace (first heated and boiled to a certain degree, which custom alone can teach) a handful or two of balls, which have been first well purged of all their loole furry substance. She then stirs the whole very briskly about with birchen rods, bound and cut like brushes; and when the heat and agitation have detached the ends of the silks of the pods, which are apt to catch on the rods, she draws them forth; and joining ten or twelve, or even fourteen of them together, she forms them into threads, according to the bigness required to the works they are destined for: eight ends sufficing for ribbands; and velvets, &c. requiring no less than fourteen. The ends, thus joined into two or three threads, are first passed into the holes of three iron rods, in the fore-part of the reel, then upon the bobbins or pollies, and at last are drawn out to the reel itself, and there fastened each to an end of an arm or branch of the reel. Thus disposed, the winder, giving motion to the reel,

reel, by turning the handle, guides the threads; substitutes new ones, when any of them break, or any of the balls are wound out; strengthens them, where necessary, by adding others; and takes away the balls wound out, or that, having been pierced, are full of water.

In this manner, two persons will spin and reel three pounds of silk in a day; which is done with greater dispatch than is made by the spinning-wheel or distaff. Indeed, all silks cannot be spun and reeled after this manner; either by reason the balls have been perforated by the silk worms themselves; or because they are double, or too weak to bear the water; or because they are coarse, &c. Of all these together, they make a particular kind of silk, called *floretta*; which being carded, or even spun on the distaff, or the wheel, in the condition it comes from the ball, makes a tolerable silk.

As to the balls, after opening them with scissars, and taking out the insects (which are of some use for the feeding of poultry;) they are steeped three or four days in troughs, the water whereof is changed every day to prevent their stinking. When they are well softened by this scouring, and cleared of that gummy matter the worm had lined the inside withal, and which renders it impenetrable to the water, and even to air itself, they boil them half an hour in a lye of ashes, very clear and well strained; and after washing them out in the river, and drying them in the sun, they card and spin them on the wheel, &c. and thus make another kind of *floretta*, somewhat inferior to the former.

As to the spinning and reeling of raw silks off the balls, such as they are brought from Italy and the Levant, the first is chiefly performed on the spinning-wheel; and the latter, either on hand-reels, or on reels mounted on machines, which serve to reel several skeins at the same time. See REEL.

As to the milling, they use a mill composed of several pieces, which may mill two or three hundred bobbins at once, and make them into as many skeins.

For the dying of silk, see DYEING.

SILPHIUM, in botany, a genus of the *syngenesia polygamia necessaria* class. The receptacle is paleaceous; it has no pappus; the calyx consists of three valves; and the radius of the corolla is dimidiated. There are six species, none of them natives of Britain.

SILVER. See CHEMISTRY. p. 79. 130

SILVERING, the covering of any thing with silver. It is usual to silver metals, wood, paper, &c. which is performed either with fire, oil, or size. Metal-gilders silver by the fire; painter-gilders all the other ways.

To silver copper or brass: 1. Cleanse the metal with aquafortis, by washing it lightly, and immediately throwing it into fair water; or by heating it red hot, and scouring it with salt and tartar, and fair water, with a small wire-brush. 2. Dissolve some silver in aquafortis, in a broad-bottomed glass vessel, or of glazed earth, then evaporate away the aquafortis over a chaffing-dish of coals. 3. Put five or six times its quantity of water, or as much as will be necessary to dissolve it perfectly, on the remaining dry calx: evaporate this water with the like heat: then put more fresh water, and evaporate again, and, if need be, the third time, making the fire towards the latter end so strong, as to leave the calx perfectly dry, which, if your silver is good, will be of a pure

white. 4. Take of this calx, common-salt, crystal of tartar, of each a like quantity or bulk; and mixing well the whole composition, put the metal into fair water, and take of the said powder with your wet fingers, and rub it well on, till you find every little cavity of the metal sufficiently silvered over: 5. If you would have it richly done, you must rub on more of the powder; and in the last place wash the silvered metal in fair water, and rub it hard with a dry cloth.

SILVERING of Glasses. See FOLIATING of Looking-glasses.

SIMIA, the MONKEY, in zoology, a genus of quadrupeds belonging to the order of primates. They have four fore-teeth in each jaw, placed near each other; the dog-teeth are solitary, and remote; and the grinders are obtuse. There are 33 species: Of these, three, *viz.* the satyrus, sylvanus, and inuus, have no tail. Other three of them, *viz.* the nemeltrina, apedia, and sphinx, have short tails. The other 27 have long tails. The specific distinctions are taken from the colour, and other circumstances.—The monkey-kind are remarkable for activity, a low species of cunning, and a facility of imitating the actions of men and other animals. The sagacity and docility of the simia are so well known, that it is needless to spend time in giving instances of either.

SIMILE, or **SIMILITUDE**, in rhetoric, a comparison of two things, which though different in other respects, yet agree in some one. The difference between a simile and comparison, is said to consist in this, that the simile properly belongs to whatever we call the quality of the thing, and the comparison to the quantity.

SIMONICAL, is applied to any person guilty of simony. See SIMONY.

SIMONIANIS, in church-history, a sect of ancient heretics, so called from their founder Simon Magus or the magician. The heresies of Simon Magus were principally his pretending to be the great power of God, and thinking that the gifts of the Holy Ghost were venal, and to be purchased with money. He is said to have invented the Æons, which were so many persons of whom the Godhead was composed. His concubine Helen, he called the first intelligence, and mother of all things; and sometimes he called her Minerva, and himself Jupiter. Simon Magus gained a great many proselytes, who paid himself and his concubine divine worship: these were the earliest heretics, and those that St. John, St. Peter, and St. Paul, in their epistles, so often warn the Christians against.

SIMONY, in ecclesiastical law, the crime of buying or selling spiritual gifts or preferments. In the ancient Christian church, this crime was always thought to be committed when men either offered or received money for ordinations. The apostolical canons lay a double punishment both of deposition and excommunication on such of the clergy as were found guilty of it. This was the first sort of simony, and that which was most properly so called; and to this the ancients reduced the exacting of any reward for administering the eucharist or baptism, or for any spiritual offices. A second sort of simony consisted in buying the spiritual preferments of the church: this was punished with deposition in any bishop, who promoted any church-officer for the sake of lucre; and the persons so promoted were to be degraded from their office. By the laws of Justinian, every elector was to de-

pose

poſe upon oath, that he did not chuſe the perſon elected for any gift or promiſe, or friendſhip, or any other cauſe, but only becauſe he knew him to be a man of the true catholic faith, of unblamable life, and good learning. This laſt ſort of ſimony was, when men, by ambitious arts and undue practices, got themſelves involved in an office or preferment to which they had no regular call, or when they intruded themſelves into other men's places which were legally filled before. The caſuiſts for the church of Rome maintain, that all compacts or bargains in which benefices are concerned, are ſimonical, when it is done without the pope's concurrence; but that, once obtained, gives a ſanction to the thing; which they found upon this univerſal propoſition, that the pope cannot commit ſimony in beneficiary matters, ſince he hath a power ſo abſolute over all the eccleſiaſtical goods and benefices, that he can unite, divide, and beſtow them in whatever manner he pleaſes.

Againſt the corruption of ſimony, there have been many canons made in our own church, which puniſhes the offender with deprivation, diſability, &c. and by a ſtatute of the 31 Eliz. it is enacted, that if any perſon, for any ſum of money, reward, gift, profit, or benefit, or by reaſon of any promiſe, agreement, grant, bond, covenant, or other aſſurance, ſhall preſent, or collate any perſon to any benefice with cure, dignity, or living eccleſiaſtical, every ſuch preſentation, or collation, and every admiſſion or induction thereupon, ſhall be utterly void, and the crown ſhall preſent for that turn; and the perſon that ſhall give or take any ſum of money, &c. ſhall forfeit double the value of one year's profit of any ſuch benefice; and the perſon ſo corruptly taking any ſuch benefice, ſhall from thenceforth be diſabled to have and enjoy the ſame.

SIMPLE, ſomething not mixed or compounded; in which ſenſe, it ſtands oppoſed to compound.

SIMPLE, in pharmacy, a general name given to all herbs or plants, as having each its particular virtue, whereby it becomes a ſimple remedy.

SIN, a breach or tranſgreſſion of ſome divine law, or command.

SINAI, a mountain of Arabia Petrea, ſituated eaſt long. 35°, north lat. 29°, and memorable on account of the law's being given to the Jews on this mount.

SINAPI, in botany, a genus of the tetradynamia ſiliquoſa claſs. The calix is open; the petals have ſtraight unguis and there is a neſtarious gland between the ſhort ſtamina and the piſtillum, and between the long ſtamina and the calix. There are ten ſpecies, three of them natives of Britain, *viz.* the nigra, or common muſtard; the alba, or white muſtard; and the arvenſis, or wild muſtard.

Muſtard-feed is an attenuant and reſolvent in a very high degree; it warms the ſtomach, and excites an appetite; but its principal medicinal uſe is external in ſinapiſms, applications made to certain parts when irritation is intended, but not bliſtering. It is uſually mixed with horſe-radish root, and other ingredients of the ſame kind, for this purpoſe.

SINAPISM, in pharmacy, an external medicine, in form of a cataplaſm, compoſed chiefly of muſtard-feed pulverized, and mixed with the pulp of figs, or with briony, garlic, onion, or the like.

SINCIPIUT, in anatomy. See **ANATOMY**, p. 156.

SINCOPORA, a promontory of Malacca in the Eaſt Indies, ſituated in 2° N. lat. oppoſite to the iſland of Sumatra, with which this cape forms the ſtraits called the Straits of Sincopora.

SINDON, in ſurgery, a little round piece of linen, ſilk, or lint, uſed in dreſſing a wound after trepanning.

SINE, or *right SINE* of an arch, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end of the arch; being always equal to half the chord of twice the arch. See **TRIGONOMETRY**, and **GEOMETRY**.

SINECURES, eccleſiaſtical benefices without cure of ſouls. **SINEW**, denotes what we properly call a nerve; though, in common ſpeech, it is rather uſed for a tendon.

SINGING, the action of making divers inflections of the voice, agreeable to the ear, and correſpondent to the notes of a ſong, or piece of melody.

SINGULAR NUMBER, in grammar. See **GRAMMAR**.

SINISTER, ſomething on, or towards the left-hand; ſiſtiter is alſo uſed among us for unlucky, though in the ſacred rites of divination the Romans frequently uſed it in an oppoſite ſenſe.

SINISTER, in heraldry. The ſiniſter ſide of an eſcutcheon is the left-hand ſide; the ſiniſter chief, the left angle of the chief; the ſiniſter baſe, the left-hand part of the baſe.

SINISTRI, a ſect of ancient heretics, thus called, becauſe they held the left hand in abhorrence, and made it a point of religion not to receive any thing therewith.

SINKING FUND, a provision made by parliament, conſiſting of the ſurplusage of other funds, intended to be appropriated to the payment of the national debts; on the credit of which very large ſums have been borrowed for public uſes.

SINOPICA TERRA, in natural hiſtory, the name of a red earth of the ochre-kind, called alſo rubrica ſinopica, and by ſome authors ſinopis. It is a very cloſe, compact, and weighty earth, of a fine glowing purple colour. It is of a pure texture, but not very hard, and of an even, but duſty ſurface. It adheres firmly to the tongue, is perfectly fine and ſmooth to the touch, does not crumble eaſily between the fingers, and ſtains the hands. It melts very ſlowly in the mouth, and is perfectly pure and fine, and of a very auſtere aſtringent taſte, and ferments very violently with aqua-fortis. It was dug in Cappadocia, and carried for ſale to the city Sinope, whence it had its name. It is now found in plenty in the New-Jerſeys in America, and is called by the people there blood-ſtone. Its fine texture and body, with its high florid colour, muſt make it very valuable to painters, and its powerful aſtringency equally ſo in medicine.

SINOPE, in heraldry, denotes vert, or the green colour in armories.

Sinople is uſed to ſignify love, youth, beauty, rejoicing, and liberty; whence it is, that letters of grace, abolition, legitimation, &c. are always uſed to be ſealed with green wax.

SINUATED LEAF, in botany. See **BOTANY**, p. 640.

SINUOSITY, a ſeries of bends and turns in arches, or other irregular figures, ſometimes jutting out, and ſometimes falling in.

SINUS, in anatomy, denotes a cavity of certain bones, and other parts, the entrance whereof is narrow, and the bottom wider and more ſpacious.

SRUUS, in surgery, a little cavity, or sacculus, frequently formed by a wound or ulcer, wherein pus is collected.

SION, a town of Switzerland, in the county of Valais, situated on the river Rhone, twenty-three miles south-east of the lake of Geneva, being a sovereign state.

SIPHON, a bended pipe, one end of which being put into a vessel of liquor, and the other hanging out of the said vessel over another, the liquor will run out from the first into the last, after the air has been sucked out of the external or lower end of the siphon, and that as long as the liquor in the upper vessel is above the upper orifice of the siphon.

SIPHONANTHUS, a genus of the tetrandria monogynia class. The corolla consists of one funnel-shaped petal, with eight segments; and there are two berries containing many seeds. There is but one species, a native of India.

SIRANAGER, a city of hither India, capital of the province of Siba, situated on the river Ganges: E. long. 80°, N. lat. 31° 30'.

SIRE, a title of honour in France, now given to the king only, as a mark of sovereignty.

SIREN, in antiquity, a kind of fabulous animal, otherwise called a mermaid.

The sirens are represented by Ovid, &c. as sea-monsters, with womens faces and fishes tail; and by others decked with plumage of various colours. The three sirens are supposed to be the three daughters of the river Achelous; and are called Parthenope, Ligia, and Leucosia. Homer makes mention of only two sirens, and some others reckon five. Virgil places them on rocks where vessels are in danger of splitting. Some represent them as such charming monsters, who sung so harmoniously, that sailors were wrecked on their rocks without regret, and even expired in raptures.

SIREN, in zoology, a genus belonging to the order of amphibia mentes. The body is naked, and furnished with two ungulated feet, and a tail. It has a great resemblance to a lizard, only it is larger. It is found in marshy grounds in Carolina.

SIRIUS, in astronomy, a bright star in the constellation canis. See **ASTRONOMY**, p. 487.

SISON, in botany, a genus of the pentandria digynia class. The fruit is oval and striated; and the involucre consists of four leaves. There are six species, three of them natives of Britain, viz. the animum, or bastard stone-parley; the fegetum, or corn-parley; and the inundatum, or least water-parley. The seed of the animum is one of the four lesser hot seeds of the shops; and is an attendant, aperient, and carminative.

SISYMBRIUM, in botany, a genus of the tetradynamia siliquosa class. The pod opens with straight valves; and the calix and corolla are open. The species are 25, seven of them natives of Britain. The young leaves of the cordamine, or ladies-smoke, and of the noisurium, or water-crests, are recommended in the scurvy, and eaten in large quantities for that intention with great success.

SISYRNCHIUM, in botany, a genus of the gynandria triandra class. The spathe consists of two leaves, and the corolla of six petals; and the capsule has three cells. There is but one species, a native of Virginia.

SITE, denotes the situation of an house, &c. and some-

times the ground plot, or spot of earth it stands on. **SITOPHYLAX**, in Grecian antiquity, an Athenian magistrate, who had the superintendence of the corn, and was to take care that nobody bought more than was necessary for the provision of his family.

SITTA, in ornithology, a genus belonging to the order of picæ. The bill is subulated, cylindrical, straight, and entire; the superior mandible being longer than the inferior, and compressed at the point; the tongue is lacerated; and the nostrils are covered with hairs. There are three species, distinguished by their colour.

SIUM, in botany, a genus of the pentandria digynia class. The fruit is somewhat oval, and striated; the involucre consists of many leaves; and the petals are heart-shaped. There are 8 species, three of them natives of Britain, viz. the latifolium, or great water-parley; the nodiflorum, or creeping water-parley; and the erectum, or upright water-parley.

SIXTH, in music, one of the simple original concords, or harmonical intervals. See **MUSIC**.

SIZE, the name of an instrument used for finding the bigness of fine round pearls. It consists of thin pieces or leaves, about two inches long and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains, or two carats, to five carats, &c. and those of the third, for pearls from six carats and a half to eight carats and a half.

SIZE is also a sort of paint, varnish, or glue, used by painters, &c.

The shreds and parings of leather, parchment, or vellum, being boiled in water and strained, make size. This substance is used in many trades.

The manner of using size is to melt some of it over a gentle fire; and scraping as much whiting into it as may only colour it, let them be well incorporated together; after which you may whiten frames, &c. with it. After it dries, melt the size again, and put more whiting, and whiten the frames, &c. seven or eight times, letting it dry between each time: but before it is quite dry, between each washing, you must smooth and wet it over with a clean brush-pencil in fair water.

To make gold size, take gum animi and asphaltum, of each one ounce; minium, litharge of gold, and amber, of each half an ounce; reduce all into a very fine powder, and add to them four ounces of linseed-oil, and eight ounces of drying-oil; digest them over a gentle fire that does not flame, so that the mixture may only simmer, but not boil; for fear it should run over and set the house a-fire, keep it constantly stirring with a stick till all the ingredients are dissolved and incorporated, and do not leave off stirring it till it becomes thick and rosy; and being boiled enough, let it stand till it is almost cold, and then strain it through a coarse linen-cloth and keep it for use.

To prepare it for working, put what quantity you may have occasion to use in a horse-muscle shell, adding so much oil of turpentine as will dissolve it; and mixing it as thin as the bottom of your feed-lac varnish, hold it over a candle, and then strain it through a linen rag into another shell; add to these so much vermilion as will make

make it of a darkish-red : if it is too thick for drawing, you may thin it with some oil of turpentine. The chief use of this fize is for laying on metals.

The best gold-fize for burnishing is made as follows : take fine bole, what quantity you please ; grind it finely on a marble ; then scrape into it a little beef suet ; grind all well together ; after which mix a small proportion of parchment lize with a double proportion of water, and it is done.

To make silver-fize : take tobacco-pipe clay, in fine powder ; into which scrape some black-lead and a little Genoa-soap ; and grind them all together with parchment-fize, as already directed.

SKAITE, in ichthyology. See RATA.

SKELTON, in anatomy. See ANATOMY, p. 151.

SKIE, one of the greatest western islands of Scotland, divided from the counties of Ross and Inverness by a narrow channel ; being upwards of sixty miles in length and twenty in breadth.

SKIFF, the least of two ship-boats, serving chiefly to go ashore in, when the ship is in harbour.

SKIN, in anatomy. See ANATOMY, p. 254.

SKIN, in commerce, is particularly used for the membrane stripped off the animal to be prepared by the tanner, skinner, currier, parchment-maker, &c. and converted into leather, &c. See TANNING, &c.

Skins and the hair of beasts manufactured become parchment and vellum ; leather, of which are made shoes and boots, saddles, harnesses, and furniture for horses, gloves and garments, coaches and chairs, household stuff, covers of books, drinking vessels, &c. and furs for cloathing, hats, caps, &c.

SKINNER, one who works in skins. See SKIN.

SKIPTON, a town in the west riding of Yorkshire, situated thirty five miles west of York

SKIRMISH, in war, a disorderly kind of combat, or encounter, in presence of two armies, between small parties, or persons, who advance from the body for that purpose, and introduce to a general and regular fight.

SKULL, in anatomy. See ANATOMY, p. 151.

SKY, the blue expanse of air and atmosphere.

The azure colour of the sky Sir Isaac Newton attributes to vapours beginning to condense there, and which have got consistence enough to reflect the most reflexible rays.

SLAB, an outside sappy plank or board sawed off from the sides of a timber-tree : the word is also used for a flat piece of marble.

SLATE, a stone of a compact texture and laminated structure, splitting into fine plates

Dr Hill distinguishes four species of slate (stegania) : 1. The whitish steganium, being a soft, friable, slaty stone, of a tolerably fine and close texture, considerably heavy, perfectly dull and destitute of brightness, variegated with a pale brown, or brownish yellow : this species is very common in many counties in England, lying near the surface of the ground, it is generally very full of perpendicular as well as horizontal cavities, many of which are filled up with a spar a little purer and more crystalline than the rest, and is commonly used for covering houses. 2. The red steganium is a very fine and elegant slate, of a smooth surface, firm and compact texture, considerably heavy, and of a very beautiful pale purple, glittering all over with small glossy spangles : it is com-

posed of a multitude of very thin plates or flakes, laid closely and evenly over one another, and cohering pretty firmly : this is very common in the northern parts of England, and is much valued as a strong and beautiful covering for houses. 3. The common blue steganium is very well known, as an useful and valuable stone, of a fine smooth texture and glossy surface, moderately heavy, and of a pale greyish blue ; composed of a multitude of even plates, laid close upon one another, and easily splitting at the commissures of them : this is also very common in the north parts of England, and is used in most places for the covering of houses. There are other species of this slate, viz. The brownish blue friable steganium, usually called coal slate ; the greyish black friable steganium, commonly called shiver and the greyish blue sparkling steganium. 4. The friable, aluminous, black steganium, being the Irish slate of the shops : this is composed of a multitude of thin flakes laid very evenly and regularly over one another, and splits very readily at the commissures of them. It is common in many parts of Ireland, and is found in some places in England, always lying near the surface in very thick strata. In medicine, it is used in hæmorrhages of all kinds with success, and is taken often as a good medicine in fevers.

There is a sort of slate-stones called, by Dr Hill, ammoschista. Of this kind there are only two species : 1. That composed only of sparry and crystalline particles ; or the grey, friable, dull ammoschistum ; being a coarse, harsh, and rough stone, of a very loose texture, considerably heavy ; and composed of a large, coarse, obtusely angular gritt, surrounded, and in part held together, by a loose earthy spar. This stone is very common in most countries, and is frequently used to cover houses, instead of tiles : it bears the weather but badly, and is apt to crumble after frosts. 2. That composed of talcy, sparry, and crystalline particles. This comprehends five species, viz. the brownish white glittering ammoschistum ; the greenish grey shining ammoschistum ; the yellowish grey glittering ammoschistum ; the hard purple and white laminated ammoschistum ; and the bluish glittering slate stone. These sorts of slate-stone are very common in the northern countries, and are used in covering houses, paving, building, &c.

SLAVE, a person in the absolute power of a master, either by war or conquest. We find no mention of slaves before the deluge ; but immediately after, viz. in the curse of Canaan : whence it is easily inferred, that servitude increased soon after that time ; for in Abraham's time we find it generally established.

Among the Romans, when a slave was set at liberty, he changed his name into a surname, and took the women or penomen of his master ; to which he added the cognomen he had been called by when a slave. Great part of the Roman wealth consisted in slaves : they had the power of life and death over them, which no other nation had ; but this severity was afterwards moderated by the laws of the emperors. The slaves were esteemed the proper goods of their masters, and all they got belonged to them ; but if the master was too cruel in his correction, he was obliged to sell his slave at a moderate price.

Slavery is absolutely abolished in Britain and France, as to personal servitude. Slaves make a considerable article

tricle of the traffick in America. The British south-sea company have, by treaty, the sole privilege of furnishing the Spanish West Indies with slaves.

SLAUGHTER. See **MANSLAUGHTER**, **HOMICIDE**, **MURDER**, &c.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, &c.

SLEEP, is defined to be that state wherein the body appearing perfectly at rest, external objects move the organs of sense as usual, without exciting the usual sensations.

Sleep is broken off unnaturally, when any of the organs of sensation is so briskly acted on, that the action is propagated to the brain.

Sleep being one of the non-naturals, it is not possible for those to preserve their health, who do not go to sleep in a regular manner: for sleep repairs the spirits, which are dissipated by watching; and consequently it restores the strength of those who are weak, indisposed, or labour much. It likewise promotes perspiration, contributes greatly to digestion, and more to nutrition. The night is the most proper for sleep; for the vigour of the mind and body are better restored in the night than in the day; thus nocturnal labour and lucubrations impair the health.

SLEEPER, or the **GREAT SLEEPER**, in zoology. See **Mus**.

SLEEPERS, in natural history, a name given to some animals which are said to sleep all the winter; such as bears, marmosets, dormice, bats, hedge hogs, swallows, &c. These do not feed in winter, have no sensible evacuations, breathe little or not at all, and most of the viscera cease from their functions. Some of these creatures seem to be dead, and others to return to a state like that of the fœtus before the birth: in this condition they continue, till by length of time maturing the process, or by new heat, the fluids are attenuated, the solids stimulated, and the functions begin where they left off.

SLEEPERS, in the glass-trade, are the large iron-bars crossing the smaller ones, and hindering the passage of the coals, but leaving room for the ashes.

SLEEPERS, in a ship, timbers lying before and aft, in the bottom of the ship, as the rung-heads do: the lowermost of them is bolted to the rung-heads, and the uppermost to the futtocks and rungs.

SLESWICK, the capital of the duchy of Sleswick, otherwise called South Jutland, situated on the river Sley: E. long $9^{\circ} 45'$, and N. lat. $54^{\circ} 45'$. See **JUTLAND**.

SLIDING, in mechanics, is when the same point of a body, moving along a surface, describes a line on that surface.

SLIGO, a county of Ireland, in the province of Connaught, bounded by the ocean on the north, by Letrim on the east, by Roscommon on the south, and by Mayo on the west.

SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity for the dexterous management of the sling: it is said they bore three kinds of slings, some longer, others shorter, which they used according as their enemies were either nearer or more remote. It is added, that the first served them for a head-band, the se-

cond for a girdle, and that a third they constantly carried with them in the hand.

SLIPPING, among gardeners, the tearing off a sprig from a branch, or a branch from an arm of the tree. Thieftort of slips take root more readily than cuttings.

SLOANEA, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals, and the calix of five deciduous leaves; the stigma is perforated; and the berry contains many seeds.

SLOATH, in zoology. See **BRADYPUS**.

SLOE. See **PRUNUS**.

SLOOP, a sort of floating vessel, otherwise called shallop. In our navy, sloops are tenders on the men of war, and are usually of about sixty tons, and carry about thirty men.

SLOUGH, a deep muddy place. The cast skin of a snake, the damp of a coal-pit, and the scar of a wound, are also called by the same appellation. The slough of a wild boar, is the bed, soil, or mire, wherein he wallows, or in which he lies in the day time.

SLUCZK, the capital of the palatinate of the same name, in the duchy of Lithuania and kingdom of Poland: situated in E. long. 27° , and N. lat. 53° .

SLUICE, in hydraulics, a frame of timber, stone, earth, &c. serving to retain and raise the water of the sea, a river, &c. and on occasion to let it pass: such is the sluice of a mill, which stops and collects the water of a rivulet, &c. in order to discharge it at length in greater plenty upon the mill-wheel; such also are those used in drains, to discharge water off lands; and such are the sluices of Flanders, &c. which serve to prevent the waters of the sea overflowing the lower lands, except when there is occasion to drown them. See **CANAL**.

SLUTTELBURG, a town of Russia, in the province of Ingria, situated on the south-side of the lake Ladogo, in E. long. $31^{\circ} 20'$, N. lat. 60° .

SLUYS, a port-town of Dutch Flanders, situate opposite to the island of Cadzand: E. long. $3^{\circ} 15'$, N. lat. $51^{\circ} 18'$.

SMACK, a small vessel with but one mast.

SMALAND, a province in Sweden, in the territory of Gothland, bounded by East Gothland, on the north; by the Baltic sea, on the east; by Blecking, on the south; and by Halland, on the west.

SMALLAGE, in botany. See **APIUM**.

SMALT, a preparation of arsenic. See **CHEMISTRY**, p: 145.

SMARAGDUS, in natural history. See **EMERALD**.

SMARIS, in ichthyology. See **SPARUS**.

SMELL, with regard to the organ, is an impression made on the nose, by little particles continually exhaling from odorous bodies: with regard to the object, it is the figure and disposition of odorous effluvia, which striking on the organ, excite the sense of smelling: and with regard to the soul, it is the perception of the impression of the object on the organ, or the affection in the soul resulting therefrom.

The principal organs of smelling are the nostrils, and the olfactory nerves; the minute ramifications of which latter are described throughout the whole concave of the former. See **ANATOMY**, p. 293.

SMELT, in ichthyology, a species of salmo, See **SALMO**. **SMELTING**, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metalline part from

from the earthy, stony, and other parts. See CHEMISTRY. *pallm.*

SMILAX, in botany, a genus of the diœcia hexandria class. The calix both of male and female consists of six leaves; none of them have any corolla; the stylus of the female is trifid; and the berry has three cells, containing two seeds. There are 13 species, none of them natives of Britain.

SMITHERY, a manual art, by which an irregular lump of iron is wrought into any intended shape, by means of fire, hammering, filing, &c.

SMOKE, a dense elastic vapour, arising from burning bodies. As this vapour is extremely disagreeable to the senses, and often prejudicial to the health, mankind have fallen upon several contrivances to enjoy the benefit of fire, without being annoyed by smoke. The most universal of these contrivances is a tube leading from the chamber in which the fire is kindled, to the top of the building, through which the smoke ascends, and is dispersed into the atmosphere. These tubes are called chimneys; which, when constructed in a proper manner, carry off the smoke entirely; but, when improperly constructed, they carry off the smoke imperfectly, to the great annoyance of the inhabitants. As our mansions at present seem to have a very imperfect knowledge of the manner in which chimneys ought to be built, we can hardly perform a more acceptable service to the public than to point out the manner in which they ought to be constructed so as to carry off the smoke entirely; as well as to explain the causes from which the defects so often complained of generally proceed, and the method of removing them.

Although we would naturally imagine, that the causes which occasion smoke in rooms are exceedingly various; yet, upon examination, it will be found that they may all be reduced to one of these three general heads, each of which will admit of several varieties.

I. To a fault in the form of the tube, or chimney itself.

II. To some fault in the other parts of the building, and a wrong position of the chimney with respect to these.

III. To an improper situation of the house with respect to external objects. And it is of the utmost consequence, in attempting a cure accurately to distinguish from which of these defects the smoke proceeds, it will be necessary to point out with care the several phenomena which are peculiar to each.

I. Of smoke occasioned by a fault in the form of the chimney itself. But, before we proceed, it will be necessary to premise something with regard to the general cause of the ascent of smoke in chimneys.

The earth is every where surrounded with a great body of air, called the atmosphere. This air is an elastic fluid subjected to many particular laws, as hath been fully explained under the article PNEUMATICS: where it hath been sufficiently demonstrated, that, like other fluids, it hath a constant tendency to preserve an equilibrium in all its parts; so that, if at any time the weight of it at one place is diminished, the heavier air rushes from all sides towards that point, till the equilibrium be again restored. We there likewise saw, that heat was one of the most powerful means of disturbing this general equilibrium of the air, by expanding it to a great degree, and making the same quantity

occupy a much greater space than before, and consequently become lighter. Hence it necessarily follows, that when ever a fire is kindled, the air immediately contiguous to it will be heated, and of consequence rarified and made light; which must ascend into the higher regions of the atmosphere, till it becomes of the same gravity with the air contiguous to it; while the denser cold air below rushes toward the point from which it departed, is there heated and rarified in its turn, and ascends in the same manner, carrying the smoke or vapour arising from the burning body along with it. In this manner that constant suction of air towards every fire is produced, and from this cause proceeds the constant tendency of smoke to ascend upwards from the surface of the earth. But as the body of our atmosphere is often agitated with wind, &c. and as it is an elastic fluid, it endeavours to spread itself every way; from which causes the warm air would quickly be diffused among the cold air before it could arise to any considerable height; so that the smoke would always remain low, and be suffocated near the surface of the earth: all of which inconveniences are avoided by confining this heated air in a tube, which prevents it from mixing with the external air, till it arrive at the height to which we desire it should ascend.

To render this still more clear, see Plate CLVI. where AB (fig. 1.) represents the tube of a chimney, having a fire at the bottom at A. It is obvious, that, in this situation the air which was heated by the fire at A, will ascend directly upwards, without mixing with the external air, till it arrives at B, beyond which it will be at liberty to disperse in the atmosphere; and the more weighty air which presses in to supply its place can have no access to it but at the opening between A and E, where it also is heated by the fire, and in its turn ascends to the top of the chimney, thereby occasioning a constant stream of air to ascend up the chimney, which carries the smoke along with it. This is the manner in which fuliginous vapours are made to ascend in chimneys; and by attending to it, we may draw the following corollaries with regard to the construction of this useful part of our habitations.

Ist, The higher the chimney, that is, the greater the distance between the fire-place and the top of the chimney, the greater will be the difference between the weight of the column of heated air in the tube, and another column of the atmosphere of the same diameter without the chimney, and consequently the air will enter with the greater force at the opening AE, and carry up the smoke more readily along with it: for as the warm air within the tube continues rarified to a high degree till it issues from the top of the chimney, and is, in every part of its length, lighter than the same bulk of external air marked by the dotted line CD, it follows, that the longer these two columns of unequal gravity are, the greater must be the difference of their weight. Hence it is, that high chimneys (*cæteris paribus*) have a greater suction of air, and are less liable to vent ill, than low ones. A smoky chimney may therefore sometimes be cured by raising it higher. It is likewise obvious, that if any opening is made into the chimney, as at F, the air will enter with less force at E, and carry up the smoke with less velocity, and by that means be in danger of producing smoke in the room; for this opening, as it admits the fresh air into the tube, has nearly the same effect as shortening the tube so much would have.

2d, As the smoke is forced up the chimney merely by the

rarefaction of the air in consequence of heat, it is evident, that the more the air is heated, with the greater force (*ceteris paribus*) will it ascend, because the difference between the weight of the external and internal air will be greater; and as the air will be the more heated the nearer it is made to pass by the fire in its entry into the chimney, it is evident, that the smaller the opening at A E is, or, in other words, the lower the mantle of the chimney is, the air will be forced to pass the nearer the fire, and therefore be more rarefied, and ascend with the greater velocity; so that lowering the mantle of the chimney will often cure smoke.

But it is frequently inconvenient to have the mantle of the chimney too low. However, the same effect may often be produced by another contrivance. For as the fire-place is usually made wider than the length of the grate, a great deal of cool air passes at the two sides of the grate without being much heated. This greatly diminishes the suction of the chimney: but it may easily be prevented by building up the vacancies at each side of the grate, so as to allow no air to enter from below, except what comes immediately through, or before the fire. For this purpose, grates consisting of a neat hewed stone at each end, with a breast and bottom of iron fitted to them, as represented at fig. 2. are extremely convenient. But the aperture of the chimney is often not suddenly contracted above the mantle, but goes up tapering slowly, as in the same fig. 2. This structure allows a quantity of cool air to enter at the two corners of the mantle, and steal up the tube without coming near the fire. The most easy and effectual method of remedying this defect, is to place a sheet of milled iron within the mantle on each side, as low down as possible, making them slant a little upwards towards the middle of the chimney; as at A, fig. 2. the mantle being represented by the dotted line. By this contrivance, the air, which enters at the side of the mantle, before it can ascend into the chimney, is forced to pass very near the fire, and of course is much rarified. The good effects of this would be still more strongly felt, if one of these plates were placed a little lower than the other, and made so long, that the ends should cross each other, as at AB, fig. 2. by which means every particle of air that went up the chimney behaved to pass immediately above the fire. It is almost unnecessary to observe, that these plates ought to be so contrived as to be taken out at pleasure to allow the chimney to be cleaned.

A chimney may not only be defective by having the mantle too high, or by being too wide from side to side, but also by being too deep between the fore side and the back, as is often the case in very old houses. In this case, the distance between the fire and the mantle is so great, that much air passes up without being sufficiently rarified, as is represented at fig. 3. This may be sometimes cured by bringing the grate a little forward, which, by making the fire act more powerfully upon the mantle, rarefies the air more in its passage. But this can seldom produce the desired effect, and it often does harm: for when the grate is brought forward, there is a great vacancy left between it and the back of the chimney, so that the air passes under the grate, and ascends behind it very little rarified; so that, if the feet of grate are not very low, there will be as much lost in this way as will be gained in the other; and as there is not enough of heated air in the chimneys of this kind to make the vapour ascend with rapidity, they are often choked with thick fuliginous vapours hanging in them, almost in equi-

librio with the rest of the atmosphere, so that the least puff of wind beats them down the chimney, and pushes the smoke into the room; whereas, when it is far back, it is driven down upon the hearth, and rises upwards again when the gulf is over, and a great deal of it is caught within the mantle as it rises, which in the other case would have been dispersed through the room. When this is the case, the most effectual method of cure is, to bring the grate forward till the forepart of it is immediately under the inner edge of the mantle; then build up the vacancy at the back of it, the whole width of the fire-place from side to side, raising it perpendicularly till it is as high as the back of the grate, and then bending it forward towards the mantle, as is represented at fig. 4. When it is as high as the workman can reach, let it be suddenly turned backward again, sloping a little upward, as in the figure; then fit a sheet of milled iron to the inside of the mantle, making it slant a little upward toward the back part, at a small distance above the new erected masonry, and extending within a few inches of the back wall, as at A, fig. 4. By this construction all the air that enters into the chimney is made to pass immediately above the fire, between it and the heated iron, upon which the flame acts with the greater force, as the back of the fire-place is bent a little forward above the grate, and the heat is likewise reflected into the room with the greater force: at the same time, if the smoke is at any time beat down the chimney by a sudden gulf of wind, it will be caught by the sheet of iron, and prevented from coming into the room. If the fire-place be very wide between the one side and the other, the new masonry may be carried quite up to the sheet of iron on each of the sides.

3d, As every fire requires a constant succession of fresh air, the tube for conveying this rarefied air to the higher regions of the atmosphere must be of a sufficient size to contain the whole of it, and allow it a ready passage; otherwise a part of it will be forced to seek some other passage; by which means, the apartment in which the fire is placed will be constantly filled with smoke. Every chimney therefore ought to have a degree of wideness sufficient to carry off the whole of the smoke arising from the fire usually burnt in it, otherwise the apartment will be almost continually filled with smoke.—This is a fault more common at present than any of those already mentioned, especially in large towns, where the number of chimneys in one wall is often so great that it is difficult to get a sufficient space for each. The most obvious cure, where the situation admits of it, is to widen the chimney, by opening a hole a little above the grate thro' the back-wall of the chimney, slanting a little upward, and building on the outside of the wall a small chimney open from that hole to the top of the building, as in fig. 5. where AB represents the new tube going through the wall at the opening at A, which will receive the superfluous smoke, and carry it off. This additional chimney must always be carried as high as the other. But as there are many situations in which this method of cure would be impracticable, we must try every method for accelerating the ascent of the smoke: (for the more quickly it ascends, the more narrow may the tube be;) and with that view, the chimney may be heightened at top, and contracted at bottom, in any or all the various ways we have mentioned. But if none of these methods prove effectual, let the chimney be built quite close at the under part, leaving only as much room as is sufficient to contain the grate, having a cover of metal fitted to that opening.

pening, which can be taken off or put on at pleasure; by which the whole air that enters into the chimney is made to pass through the fire like a furnace, and carries the smoke up it with great velocity. These are well known in large towns by the name *smoke-chimneys*: but as they occasion a prodigious waste of fuel without warming the room, and, unless attended with very great care, are in danger of setting the building on fire, they ought to be as much avoided as possible. But if neither this, nor any of the other methods prove effectual, the wall must either be taken down and rebuilt in a proper manner, or the chimney abandoned as incurable. As this is a defect more difficult to be remedied than any other, we would strongly recommend it to every builder to build his chimneys of a sufficient width throughout; there is no danger of erring on this extreme, as it is easy to remedy any defect that might arise from it.

4th, As the air which ascends through the chimney continues nearly of an equal degree of heat to the top, the tube should be of an equal degree of width at the top as at the bottom, as well as through the whole of its length. It ought not therefore to be made tapering gradually from the fire-place to the top, but to be suddenly contracted above the grate, as in fig. 6. from which it ought to be continued of an equal wideness throughout its whole length; but if it is narrower at any one place than another, it ought to be at the under part, immediately above the fire, for a very short space; because, as this is within reach of the hand, the foot can be cleaned from it as often as is necessary, so that when the other parts of the chimney are full and clogged with soot, they will not be narrower than this place is at that time.

5th, It seldom happens that a chimney can be carried quite straight upwards: and it is an advantage that it is so, as they ought always to be bent a little. For if a chimney be straight, and of a proper width to transmit the smoke and no more, it will not be sufficient for that purpose, when there is a heavy fall of rain, or snow, or hail, with little wind; for the great drops will fall perpendicularly from the top to the bottom of the chimney; and as they occupy a considerable space, the smoke will not have room to ascend, but must be forced down with the shower, and dispersed in the apartment: whereas, if the chimney is bent, the rain falls upon some of the sides, and glides gently down without disturbing the ascent of the smoke. The same inconvenience will be felt in a straight chimney, where it is so placed as to be exposed to winds, which sometimes enter the top and blow down with a sudden puff: for, if it be straight, the air meets with no interruption till it descends into the chamber, and there disperses the smoke; but if it be crooked, the descent of the wind will be obstructed, its force broken, and the bad effects of it in a great measure prevented. Upon the whole, bent chimneys are always preferable to straight ones. However, a perpendicular chimney may be easily cured, by some of the contrivances after mentioned.

These are the most general defects arising from the structure of the chimney itself, which are all reducible to the following causes: 1. Too little height; 2. Too great wideness of the bottom of the chimney; 3. Too little width; 4. Unequal wideness between the top and bottom; and, 5. Straightness of the tube. We have pointed out the best methods of curing each of these defects; and to fi-

nish our remarks on this general head, and give the reader a more perfect idea of the best form of construction for a chimney, we have drawn two different sections of one constructed on the justest principles, in figures 6. and 7. the several parts of which appear so plain from the figures, and the reasons for this construction have been already so clearly assigned, that a very short explanation will be sufficient. Figure 6. represents a front-view of the fire-place; supposing the fore-part of the wall taken down, and the chimney laid bare from top to bottom; AB, and DC, representing the two sides of the fire-place; and BC, the mantle, being cut through, to shew the manner in which the aperture is suddenly contracted, immediately above the fire within the mantle. The tube from the point E, to the top, ought to be of an equal wideness, and bent in any direction that may be convenient. The two planes, FF, represent the two sides of the fire-place, which ought to be as much sloped inward towards the back as the form of the grate will admit of; for the more they are inclined, the more powerfully will they reflect the heat into the apartment. Fig. 7. represents a perpendicular section of the wall, through the middle of the chimney, to discover its shape, if viewed from a side. And here it is to be observed, that it ought ever to be a rule to bring the building at the under part of the chimney immediately behind the grate, as far forward as possible, because this throws more heat into the chamber than if it were placed farther back: but as the fore-part of the grate ought never to project beyond the inner edge of the mantle, care should be taken to have the under part of the mantle wrought as thin as the nature of the materials will admit of, making it thicker towards the upper part, so as to slope inwards above the fire, as represented at B, fig. 7. To throw the heat outward, let the upper part of the back of the fire-place be a little inclined outward, as at C; but, after it is carried up in this manner a little higher than the mantle, let it be suddenly turned back, as in the figure, the projection above the mantle inclining backward in the same direction, being carried up to the top at an equal wideness the whole way.

Although it is necessary to have all chimneys pretty wide; yet this, on many occasions, is attended with inconveniences: for as they transmit a great quantity of heated air, too large a portion of that warm air which ought to heat the chamber is carried off; and as it is only when the fire is first kindled that the great quantity of gross vapour is exhaled which fills the chimney, and maketh a large tube necessary, if it were so contrived as to contract or dilate at pleasure, we might have our chimney of a sufficient width to convey away the greatest quantity of smoke that could ever have occasion to pass through it, at the same time that we might never allow more air to pass off at other times than was necessary to carry away the whole of the smoke, by which means a much smaller quantity of fuel would keep our apartment equally warm. This we apprehend might be accomplished by the following simple apparatus. Let a sheet of milled iron be fixed at the upper part of the mantle, on the inside, at B, in such a manner, as that, by means of a small wire *de*, passing through a small hole left for that purpose in the fore-part of the chimney, it might be let down at pleasure towards C, or drawn up towards B, so as to apply quite close to the upper edge of the chimney between B and C. This would leave the tube of

its shut valves when necessary, or close it to any degree at pleasure, with the greatest ease *. It is unnecessary to add, that the plate at A fig. 4. might be employed in the same manner, when it should be found convenient. So much for what relates to the construction of the chimney itself. We now proceed to consider the second general cause of smoke, viz.

II. Of smoky houses proceeding from faults of other parts of the building, altogether independent of the structure of the chimney itself.

1st, The first we shall mention is too great closeness of the room. Smoke, as shewn above, is impelled up the chimney by the pressure of the air entering at the fire-place and ascending upwards; but, if fresh air is not admitted into the apartment in sufficient quantities to supply the consumption by the fire, the room will be quickly exhausted, and the air in it become as light as the external air at the top of the chimney, so that the smoke will as readily be dispersed into the chamber as through the chimney. But if any door or window is opened so as to admit plenty of free air, the smoke will be quickly dispelled, and the proper circulation established: the same effect will be produced by making a small hole in some of the sides of the room; but unless this be done with some judgment, it may frequently add to the disease, as it may concur with some of the other causes of smoky houses, to be afterwards mentioned. A better method of remedying this evil would be to have a small hole made in the wall at the back of the chimney, and immediately underneath it: or a small perforation, made in the wall in any other convenient manner; the one end of which should communicate with the external air, and the other communicate with the chamber in any place near the grate, and as low down as possible, through which a constant supply of air would be administered to the fire without the smallest inconvenience or trouble. If this were practised, doors and windows might with safety be made much closer than at present, and our apartments rendered equally warm and comfortable with a much smaller quantity of fuel than we use at present. For as the fire, in the present mode of constructing chambers, is kept alive by a constant succussion of cold air from the doors, windows, and other crannies of the room rushing towards the chimney in all directions, the air of the room, which, if not cooled by this means, would be quickly heated to a great degree, is constantly kept cold in spite of the strong heat of a blazing fire; which, at the same time that it scorches the parts of our body which are most exposed to it, does not warm the parts which are turned from it; and we experience at the same time a burning heat and piercing cold, which is often productive of the most disagreeable effects. But if the fire were supplied with air in the manner abovementioned, there would be less air drawn in through the crannies of the room,

so that the air within would be soon warmed, and continue long so even with a small degree of heat. However improper this might be for people in perfect health, it might surely be of great use for those who are in a weakly habit of body; especially if care were taken to carry off the foul air, by having a small tube leading from the upper part of the room to the top of the house, through which the air which had been rendered noxious by the smoke of caniles or perspiration would be conveyed away, and a succussion of fresh air admitted from the tube near the fire-place to supply that want. That the reader may more readily comprehend what is here meant, we have represented in fig. 6. a view of two small tubes for this purpose supposed to be laid open by taking away the boxing or inner coating of the wall which ought to cover them. These are of wood, and must not be above one inch in diameter. One end, *g g*, goes quite through the outer wall of the house, and communicates with the open air, having a small grate upon it to prevent vermin from entering. The other end, *h h*, passes behind the two flues at the side of the fire-place, and opens in the inside of the fire-place at *i i*, at which place they have each of them a small bit of brass fitted to them, being closed with two sliding doors exactly like those that are used to cover the end of telescopes by means of which more or less air may be admitted at pleasure.

2d. A second cause of smoke, is the wrong position of doors and windows, with respect to the fire-places.

As the smoke is impelled up the chimney by the pressure of the air, if that air is driven away from the fire-place by any cause more powerful than the suction occasioned by the fire, the smoke must also be drawn away with it, and follow the same directions with that current of air; so that whatever tends to draw a current of air from the under part of the chimney, will also tend to produce smoke in the house; from whence it is easy to conceive how doors or windows may occasion smoke when the wind is in certain directions. Thus, suppose a chamber, A, B, C, D, fig. 8. having a door or window at E, and a her at F, and a fire-place at G; when the wind is in the direction D A or C B, the general current of air will occasion a sort of suction at the opening E, so that the air will be drawn from the chimney G towards E: and if the current be strong, and the opening at E large, it will become more powerful than the suction of the chimney, and produce smoke in the apartment. If the window at F should be opened in this case, it would not mend the matter; for any wind which should enter at F, would be carried straight out at the opening E, and the current of air would be drawn from the chimney as strong as ever. If the window at E were shut, and that at F left open, and the wind still continued in the same direction as before, the current of air rushing past the window would have a tendency to draw the air of the room along with it, and

* If any one should think, that the wire *d* would be a disagreeable object in the middle of a chimney-piece, it might easily be hid by a picture of any kind. The wire might be fixed to a small brass-handle moving freely upward and downward like that for a bell; only this should have a long slit in the middle of it, with notches on each side, to receive a pin placed in the middle of the slit, by means of which the wire might be lengthened or shortened at pleasure. The whole of this apparatus is represented at fig. 16. where (a) represents the wire fastened to the brass-plate; (b) a piece of brass, raised a little, to serve as a handle. The slit in the middle is represented by the dark line, having notches *c c c* at convenient distances. The pin *d* is fixed into the wall, but left at liberty to turn about with ease; and its head stands up a little, so as to be easily turned with the finger and thumb. The body of this nail is made so thin in one direction, that when it is turned half round, it easily passes through the slit in the plate; but in the other direction its diameter is greater, so that when the plate is brought so as to have one of the notches opposite to the nail, and it is then turned half round, it catches the plate so that it cannot be moved till the nail is again turned about.

and occasion smoke, but not so powerfully as if the window at E were open; but if the wind were in the direction D B, it would be very bad: but if it blew in the direction C A, the case would be very much altered; for then a quantity of air being forced in at the opening F, and finding no ready passage, it would be pent up in the chamber, and force itself up the chimney with violence. We omit mentioning what would be the effect if the wind were in other directions, as it is imagined there will be sufficiently obvious to every attentive observer. It is only necessary here to observe, that as doors or windows are seldom so exactly made, but they produce some effect, as they always admit some air even when shut, and often occasion smoke when the wind blows from a particular quarter; and as workmen and others generally apprehend, when houses are troubled with smoke in this manner, that it is occasioned by some external cause, and apply their attention to cure it by altering the top of the chimney, which never can produce the smallest service in this case; we would recommend a more particular attention to be paid to the situation of doors and windows than is generally bestowed: especially in such situations where they are exposed to any violent current of air in a particular direction, as in narrow lanes, or desiles of any fort, where the wind, when in particular directions, is hurried along with a prodigious rapidity. And, that the effects of different positions may be still more obvious, we shall produce several other examples.

Suppose a chamber, fig. 9. having a door at A, and two windows B C, with a fire place D. If the wind came in the direction D A, and if the door transmitted as much or more air than was admitted at both the windows, a current of air would run from all parts of the chamber towards A, and therefore would have a tendency to occasion smoke: but if as much or more air came in at the windows than could get out at the door, there could be no such current; but, on the contrary, it would be forced up the chimney, and carry the smoke along with it: wherefore in this situation, a room might sometimes be cured of smoke, by making the door as close as possible; nothing could be more hurtful in this case than boring a hole in the door. But if the house was in such a situation as to be more frequently exposed to a wind which came in the direction of A D, it would run little risk of being troubled with smoke.

Suppose a room, fig. 10. having a door at A, and two windows B and C, with a fire-place D. If the wind came in the direction C B or B C, and both the windows were open, it is evident that the smoke would be drawn from the chimney by the strong current of air passing through the room; or if the window upon which the wind came were closed, and the opposite one open, nearly the same effect would be produced: but if the window upon which the wind blew were open, and the opposite one and the door shut, the room would be immediately cleared of smoke entirely. In this situation, it is evident, that if the windows were badly made, so as to admit much air, it would tend to occasion smoke, especially if the door were in the same situation; it is therefore of consequence to attend to this circumstance in a situation similar to this.

Having premised so much with regard to single rooms, we shall now proceed to consider a more compound structure. Thus, let fig. 11. represent a building consisting of two chambers, K L, joined by a passage. The chamber K having a door B communicating with the passage, a window

F, and fire-place G; and that at L having a door C, another door or window D, the window E, and fire-place H, the entry to the whole being by the door A. Let us now consider what would be the effect of the wind coming from different directions upon this building. And first, suppose the wind blew in the direction A M: If all the doors and windows were close shut, and very little air were admitted, there would be little risk of smoke; but as there would surely be some admitted through these different openings, there would be some chance that the chamber L would be troubled with smoke, because of some the air which forced its passage through the chinks of the door A would pass through the doors C and D, which might produce smoke in a small degree. There would be little chance that the chamber K would smoke in this case; because although there is a general suction through the passage from B to D, yet as it is in some measure interrupted by the close door at C, it will be but small; and as the wind is interrupted in its course by the wall of the passage, some of it will be forced through the chinks of the window F, which would more than counterbalance the effects of the other suction. But if the door D were open, both the chimneys would smoke; especially if the doors B and C were open also, as the current would be then very strong towards that point. But in all cases the smoke of this house would be prevented by keeping the door at D shut, and that at A open; but if the house was in such a situation as to be more exposed to that wind than any other, it would be better to close up the door D altogether. If the wind more commonly came from M towards A, it is more than probable that a house situated like this would be quite free of smoke, as the general current of air would be towards the chimneys; but the chamber K would run greater risk than L, as the suction might sometimes be drawn towards the window F; but if the door A were in the opposite side of the passage, that inconvenience would be avoided also. If the more general current of air were from K towards L, this house behaved to be troubled with smoke unless the windows were very close: but there would not be the smallest chance for that, when it came from L towards K.

We might now proceed to give more examples of this sort: but as it would be impossible to enumerate all the variety of cases that might occur, it is imagined that these will be sufficient to give the reader an idea of the manner in which any building ought to be examined in this respect; and he must be left to his own discretion to apply the principles above explained to all the variety of cases that may occur. In large complicated buildings, it so doubt requires a greater extent of thought to combine all the various circumstances together, and draw a general conclusion, than in smaller and more simple ones; but if the following general rules are attended to, the complaints arising from this cause would be but few. 1st, Avoid as much as may be long passages leading to very distant parts of a building, as there is often a strong current of air in these which helps to disturb the free circulation of air up the chimneys. 2^d, Place the chimneys in general in that side of the apartment towards which the wind which in general prevails most in the situation where the house is placed blows: And, 3^d, make as many, if not more, doors and windows (especially such as have occasion to be most frequently open) on that side of the building from whence the most prevalent wind does come.

III^d. The third general cause of smoke in houses is the

wrong position of the house with regard to external objects, which, by interrupting the course of the air, makes it assume various directions, and wheel about in eddies, so as to prevent it from ascending with ease from the chimney top, or beats it down into the room with violence. This is more seldom the cause of smoky houses than either of the two before mentioned; although it seems to be almost the only one attended to by the persons who pretend to cure smoky houses at present, as most of their remedies are adapted to remove the disorders arising from this cause alone. We shall briefly point out the several cases in which this can occur, that every one may be enabled to judge for himself when these cures are proper or not.

The air (as has been said) is a fluid, and wind a current of that fluid; which, when driven along the surface of the earth, flows with a smooth and equal stream, unless when opposed by some object which interrupts its course; but when it meets with any object which directly opposes its course, it is in some measure pushed back again, and made to spread on every side, till it meets with some open side, towards which it flows with great impetuosity. It is likewise a fluid of considerable gravity, and therefore presses upon the surface of the earth with great force; so that, when a current of it flows along the surface of our globe, it has a tendency to move forward and press downward at the same time: from whence it happens, that when a current of air is forced over the top of any high object, the side of which descends perpendicularly downward, the velocity of the current at first overcomes the gravity, and it flies a short way over in that direction; but the power of gravity acting upon the under surface, draws it downward, and in a short time overcomes the impetus that it had to rush forward, and occasions a sort of eddy nearly similar to what we see among water behind a stone which interrupts the violence of its currents.

To illustrate this more plainly, let AB, fig. 12. represent a part of a high building, near to which is a smaller one CD; and let the dotted line EF represent a current of air flowing with considerable force in the direction FE. It is plain that it will flow straight forward over the top of the small building; but when it meets with the large object, it will be interrupted in its course, and spread itself on every side, as represented by the dotted lines GG &c. at last it will flow towards that place through which it can escape with the greatest ease. If the opposing object be large, and has no opening through which it can issue near the ground, then it will ascend to the top of it, and flow off in that direction, carrying the smoke which ascends from the small chimney C along with it: but if there is any opening below, either a street or lane, or any other passage that will admit the wind to pass, then will the natural gravity of the air draw the general current downward to flow off through the lower passage; in which case, the smoke which ought to ascend through the chimney C, meeting with a current of air opposing its passage, will not be at liberty to issue forth, but be forced back again into the room from whence it proceed, unless some contrivance is fallen upon to prevent it.

Again, let A, fig. 13. represent a small building at the side of a great rock B, and the wind coming in the direction C D; when the current of air comes to the point D, being hurried forward with great velocity, it goes a little forward, but soon descends downward, and gradually is reflected more

and more inward, as represented by the dotted lines E E, &c. so that, descending downwards upon the top of the chimney A, the smoke is beat back again into the apartments. Thus it is that low houses, when contiguous to high objects, are in danger of being disturbed with smoke. If the contiguous object be not very high, the disorder may be cured by heightening the chimney of the low house; but if it is very high, it will be necessary to cover the top of the chimney in such a manner as to prevent the wind from entering it, at the same time that a passage is left at some of the sides through which the smoke may issue with freedom. Many are the contrivances which have been invented for this purpose, which are to be met with every where; and as there is no difficulty in accomplishing the desired end by an infinite variety of methods, every one who needs such a thing may please his own fancy in the choice. We have thought it unnecessary to add any more but one kind of these, fig. 14. which will answer the end effectually.

It is evident that houses situated near high hills, or thick woods, will be in some measure exposed to the same inconvenience; but it is likewise plain, that if a house be situated upon the slope of a hill, as at F, fig. 13. it will not be in any danger of smoke when the wind blows towards that side of the hill upon which it is situated; for the current of air coming over the house-top in the direction G H, is immediately changed by the slope of the hill to the direction H C, which powerfully draws the smoke upward from the top of the chimney. But it is also evident, that a house in this situation will be liable to smoke when the wind blows from the hill: for the current of air coming downward in the direction C H, will beat downward on the chimney F, and prevent the smoke from ascending with freedom. But the effect will be much heightened, if the doors and windows are chiefly in the lowermost side of the house.

These are some of the most general circumstances which prevent the free ascent of smoke, arising from external objects: but there are many other lesser causes which may at times occasion smoke, all of which it would be tedious here to enumerate; such as, blasts of air, reflected from the sides of mountains, and coming down valleys with great impetuosity, occasioning, in particular situations, eddies or whirlwinds of different sorts. In short, whatever in any measure disturbs the free motion of the air, is in danger of producing sudden gusts, which may occasion smoke. Therefore, whoever builds in a situation which is not altogether free, may lay his account with having some sudden gusts of smoke, unless he forms the top of his chimney so as to obviate it. And there are some situations so much exposed to sudden gusts of wind, sometimes whirling round, sometimes beat suddenly downward, or as suddenly carried up again, that it is difficult to guard against every danger. In these situations we would recommend something of the form of what is represented at fig. 15. which would be proof against every wind whatever.

Having thus traced the causes of smoky houses, and reduced them to distinct classes for the sake of distinctness, it is necessary, before we quit this subject, to observe, that in many cases, two or more of these may be combined to augment the malady, and therefore it is necessary to have all these circumstances in view in every particular case. It now only remains that we point out the several phenomena which may lead us to distinguish from which of these general causes the disorder complained of may proceed. And,

1st, If it is owing to a fault in the construction of the chimney itself, it will smoke almost continually especially in calm weather.

2d, If it does not smoke in calm weather, or only when the wind comes from some particular quarter, and can then be cured by opening some door or window, the fault may be looked for in the distribution of the doors or windows of the house. The only case in which there is a difficulty to distinguish whether it is owing to the fault of the chimney or the house, is when it proceeds from too much closeness of the apartment. But this may be easily known by trying it in a calm: for if it proceeds from this cause, there will be no smoke in a perfect calm, if the doors are left open; whereas, if the defect proceeds from a fault in the chimney itself, it will still continue to smoke when calm, even when the doors are open.

3d, When the smoke is occasioned by external causes, there can be generally seen; but it may be likewise known by this, that it descends in sudden puffs with great violence at times, even when the doors and windows are not altered. By attending to these few rules with care, there will be little danger of mistaking the cause from whence this disorder proceeds.

We shall conclude these observations with a few remarks on some particular cases which can hardly be reduced to any of the foregoing heads. And,

1st, It sometimes happens, that the smoke is prevented from ascending with freedom, by having a small part of the top of the chimney broke down, so as that some parts of it remain higher than others, which in some measure reduces it to the state of a chimney at the side of a higher one. To prevent this, it is always proper to have the top of the chimney finished with stones neatly cut and firmly built. It is not to be doubted but that those things which are placed upon particular chimneys with a view to cure them of smoke, do often, from the same cause, hurt the neighbouring chimneys built in the same wall.

2d, A chamber is sometimes filled with smoke, when a fire is kindled in a neighbouring chimney, and none in it, although there is no appearance of smoke when it has a fire burning in its own grate. This may sometimes proceed from a small hole breaking through the thin partition that divides the two chimneys from one another: and as smoke is a weighty body, which is only buoyed up by the warm air which passes through the fire, when it penetrates into the cold chimney it naturally subsides, and comes down to the chamber with which the chimney communicates, when there is no fire to carry it off. But this disease is generally produced by the smoke entering at the top of the chimney, and descending downwards: if this last is the case, it may be cured, on many occasions, by setting a pretty high stone at the top of the chimney, as a division between each two: but the surest method in all cases, is to have a smoke-board exactly fitted into the chimney above the grate, which on all occasions effectually prevents it.

3d, It frequently happens, that a chimney does not carry off the smoke well at first when the fire is kindled, although there is not the smallest tendency to it at other times. This proceeds from the narrowness of the chimney; for when the fire is kindled, the whole tube is filled with cold air, as weighty as that in the apartment; and being expanded by the fire at the bottom, it endeavours to ascend upward, but being pent in by the narrowness of the tube, and pressed by

the column of cold air above it, it is some time before it can wholly overcome that resistance, and some of it is forced into the chamber, till by degrees the whole chimney is heated, and then it vents quite well. If the smoke produced by this means is not very troublesome, it may be borne with; but if it be extremely disagreeable, it may be cured by having a large sheet of milled iron, large enough to reach between the two sides of the fire-place, and as deep as to reach from the mantle to the grate, or lower, which might by any contrivance be hung up before the fire at that time to act in some measure as a *smoke-chimney*. This would quickly make the fire burn, and carry off the smoke entirely. After that is effected, it might then be removed, till another occasion.

SMOLENSKO, the capital of a province of the same name in Muscovy, situated on the confines of Poland: in E. long. 32°, and N. lat. 56°.

SMUGGLERS, in law, those persons who conceal or run prohibited goods, or goods that have not paid his Majesty's customs.

SMUT, in husbandry, a disease in corn, when the grains, instead of being filled with flour, are full of a stinking black powder.

There are two remedies for the smut, recommended by writers on husbandry; *viz.* sleeping the seed in salt brine, and changing the seed.

As to the sleeping of seed, when wheat is intended for drilling, it must be soaked in a brine of pure salt, dissolved in water, since urine is found to be highly prejudicial. The most expeditious way of brining wheat for drilling, is to lay it in a heap, and wash it with a strong brine sprinkled on it, stirring it up with a shovel, that it may be all equally brined, or wetted with it; after this, sit on some fine lime all over the surface, and stir it up, still sitting on more in the same manner till the whole is dusted with the lime: it will then be soon dry enough to be drilled without farther trouble. It must be quicklime, in its full strength, that is used on this occasion.

The bread made of smutty corn, is very pernicious, acting as a narcotic, and occasioning not only sleepiness, but vertiges, and even convulsions.

SMYRNA, a city and port-town of Asiatic Turkey, situated on a bay of the Archipelago, in the province of Ionia, in Lesser Asia, 100 miles north of Rhodes, and 200 miles nearly south of Constantinople: E. long. 27°. N. lat. 37° 30'.

SMYRNIUM, in botany, a genus of the pentandria digynia class. The fruit is oblong, and striated; and the petals are sharp-pointed, and carinated. There are five species, only one of them, *viz.* the *olusatrum*, or alexanders, a native of Britain.

SNAFFLE, in the manege, is a very slender bit mouth, without any branches, much used in England; the true bridles being reserved for the service of war.

SNAIL, in zoology. See **LIMAX**.

SNAKE, in zoology. See **ANGUIS**.

SNAKE-ROOT, in botany. See **POLYGALA**.

SNAKE-WEED, in botany. See **POLYGONUM**.

SNAPDRAGON, in botany. See **ANTIRRHINUM**.

SNEEZING, a convulsive motion of the muscles of the breast, whereby the air is expelled from the nose with much vehemence and noise.

Sneezing is caused by the irritation of the upper membrane

brane of the nose, occasioned by acid substances floating in the air, or by medicines called sternutatories.

SNETHAM, a market-town of Norfolk, twenty-eight miles north-west of Norwich.

SNIEP, in ornithology. See TANTALUS.

SNOW, a meteor produced in this manner: When the vapours are become considerably condensed, yet not so far as to be liquified, or dissolved into water; then, by a special degree of coldness in the upper region of the air, the particles of the condensed vapour are changed into ice; several of which adhering together, form little fleeces of a white substance, somewhat heavier than the air; and therefore descend in a slow and gentle manner through it; being subject, by reason of its lightness, to be driven about by the various motions of the air and wind; and is what, when arrived to the surface of the earth, we call snow.

Snow fructifies the ground; for instance, by guarding the corn or other vegetables from the intense cold of the air, especially the cold piercing winds.

SNOWDON-HILL, the highest mountain in Wales, situated in Caernarvonshire.

SNOW-DROP, in botany. See GALANTHUS.

SNUFF, a powder chiefly made of tobacco, the use of which is too well known to need any description here.

SOAL-FISH, in ichthyology. See PLEURONECTES.

SOAP, a kind of paste, sometimes hard and dry, and sometimes soft and liquid, much used in washing, whitening linens, and by dyers, fullers, &c. See CHEMISTRY, P. 93, 149, 154.

The pure hard soap is the only sort intended for internal use. This, triturated with oily or resinous matters, renders them soluble in water; and hence becomes an ingredient in pills composed of resins, promoting their dissolution in the stomach, and union with the animal fluids. Boerhaave always prescribed soap in resinous pills, unless where an alkaliescent or putrid state of the juices forbade its use. From the same quality, soap seems well fitted for dissolving oily or unctuous matters and viscidities in the human body; thereby opening obstructions, and detaching all the vessels it passes through. It is likewise a powerful menstruum for the calculus, or stone in the bladder; a solution of it in lime-water being one of the strongest dissolvents that can with safety be taken into the stomach: the virtue of this composition is considerably greater than the aggregate of the dissolving powers of the soap and lime-water when unmixed.

SOCAGE, an ancient tenure, by which lands were held on condition of ploughing the lord's lands, and doing the operations of husbandry, at their own charges.

SOCOCCUS, in antiquity, a kind of high-shoe, reaching above the ankle, worn by comedians, as the cothurnus was by tragedians.

SOCIETY, in general, denotes a number of persons united together for their mutual assistance, security, interest, or entertainment.

The social principle in man is of such an expansive nature, that it cannot be confined within the circuit of a family, or friends, of a neighbourhood: it spreads into wider systems, and draws men into larger communities and commonwealths; since it is in these only, that the more sublime powers of our nature attain the highest improvement and perfection of which they are capable.

Royal SOCIETY, an academy or college, established by charter, by king Charles II. for promoting natural knowledge, and useful arts, by experiments.

It consists of several hundred fellows, or members, mostly British; some persons of the highest rank and many eminent gentlemen and learned men of other nations. Their meetings are held once a week, at their house in Crane-Court, Fleet-street, London; where they discourse upon the productions and rarities of nature and art, and consider how the same may be improved for the good of mankind: here are also read letters, and other philosophical papers, sent by ingenious persons both at home and abroad; upon which they discourse in the plainest manner, without affecting studied speeches.

This society, of which his Britannic majesty is perpetual patron, is governed by a council of twenty-one members; ten of whom are yearly chosen out of the society, on St. Andrew's-day. The chief of the council bears the title of president, whose proper office is, to call and dissolve the meetings; to propose the matter to be debated; call for experiments; and admit such members as shall be elected, which must be by a majority of at least twenty-one votes; where upon he is admitted, after paying 40s. and subscribing that he will endeavour to promote the good of the Royal Society of London by the improvement of natural knowledge; and being thus admitted, he afterwards pays 13s. a quarter, as long as he continues a member of the society.

SOCIETY for the encouragement of arts, manufactures, and commerce. The public spirit of this age is no where more remarkably shewn, than in the flourishing condition of this valuable society, whose object is the improvement of the polite, useful, and commercial arts, in all their various branches, by exciting industry and emulation among all who can be stimulated by honorary or pecuniary rewards. It was set on foot in the year 1753, by the Lord Falkstone, Lord Romney, Dr Hales, and seven or eight private gentlemen, who were brought together by the unwearied pains of Mr William Shipley, who had long laboured to reduce into practice a scheme he had formed for this purpose. This society, at their second meeting, determined to make a beginning, by proposing rewards for the discovery of cobalt, for the encouragement of boys and girls in the art of drawing, and for the planting of madder in this kingdom. And now money being wanted, a voluntary subscription was begun; soon after which a plan was drawn up for forming, regulating, and governing the society: and now the utility of such a society became so well understood, that immediately several noblemen and gentlemen offered themselves as members; and ever since that time, its increase has been so extraordinary, that it consists of several thousand members, among whom are most of the nobility and persons of large fortunes in the kingdom. The officers of this society are, a president, eight vice-presidents, a register, a secretary, and an assistant-secretary, who are all chosen by ballot annually on the first Tuesday in March. Every person desiring to be a member of this society must be proposed by three members: his name, addition, and place of abode, being read aloud by the secretary, he is ballotted for at the next meeting: he shall be deemed a perpetual member upon payment of twenty guineas, or a subscribing member upon payment of any sum not less than

than two guineas annually. Ladies are also admitted members, and foreigners are likewise admitted as honorary or corresponding members. The money of the society is placed in the bank of England, in the name of the president and vice-presidents, three of whom are empowered to draw any sum the society shall order to be paid. The society's office is opposite to Beauford buildings in the Strand, in London, where their meetings are held every Wednesday evening, from the second Wednesday in November, to the last Wednesday in May, and at other times every first and third Wednesday of every month.

SOCIETY for the reformation of manners, and putting in execution the laws against immorality and profaneness. It was set on foot about forty years ago, by five or six private persons in London, but is since exceedingly increased by numbers of all denominations. A particular body of the most considerable hereof, bear the expence of prosecutions, &c. without any contribution from the rest. These chiefly apply themselves to the prosecuting people for swearing, drunkenness, and prophaning the sabbath. Another body, of about fifty persons, apply themselves to the suppressing lewdness, and by them about five hundred lewd houses have been actually suppressed; a third body consists of constables; and a fourth of informers. Besides these, there are eight other regular mixed bodies of house-keepers and officers, who inspect the behaviour of the constables and other officers, assist in searching disorderly houses, seizing offenders, giving information, &c. There are several other societies of this kind at Bristol, Canterbury, Nottingham, &c.

SOCIETY for propagating the gospel in foreign parts, was instituted by king William, in 1701, for securing a maintenance for an orthodox clergy, and making other provisions for the propagation of the gospel in the plantations, colonies, frontiers, &c. To that end he incorporated the archbishops, several bishops, and other nobility, gentry, and clergy, to the number of ninety, with privilege to purchase two thousand pounds per year, inheritance and estates for lives or years, with other goods to any value. They meet yearly on the third Friday of February, to chuse a president, vice-president, and other officers; and the third Friday in every month to transact business, depute fit persons to take subscriptions for the said uses, and of all moneys so received to give account to the lord chancellor, &c. They have a standing committee at the chapter-house, to prepare matters for the monthly meeting which is held at St. Martin's library.

SOCIETY for propagating Christian knowledge. This was begun in 1699 by some persons of worth, &c. Its original design was to propagate religion in the plantations, to secure the pious education of the poor at home, and to reclaim those that err in the fundamentals of Christianity. In the year 1701, they had procured considerable charities, and transmitted the same to the plantations, in libraries, bibles, catechisms, &c. with a voluntary maintenance for several ministers to be employed in the plantations; but the society for propagating the gospel in foreign parts being then instituted, they were incorporated by charter in the same, and thus discharged as a particular society from the further pursuit of that branch of their original design; whereupon they wholly turned themselves to the other, and are now very considerable by great accessions

from the clergy and laity. They meet weekly to concert measures for raising charity for educating poor children, and setting up schools for that purpose, as also for the more regular disposal of books for the instruction of the ignorant, erroneous, &c.

For the other societies established by charter, see COLLEGE, COMPANY, CORPORATION, and STOCKS. SOCIETY, in Scots law. See LAW, Tit. xxii. 5. SOCH CRIMINIS, in Scots law. See LAW, Tit. xxxiii. 50.

SOCINIANS, in church-history, a sect of Christian heretics, so called from their founder Faustus Socinus, a native of Sienna in Italy. He, about the year 1574, began openly to declare against the catholic faith, and taught, 1. That the eternal Father was the one only God; that the Word was no more than an expression of the Godhead, and had not existed from all eternity; and that Jesus Christ was God no otherwise than by his superiority above all creatures who were put in subjection to him by the Father. 2. That Jesus Christ was not a mediator between God and men, but sent into the world to serve as a pattern of their conduct. 3. That the punishment of hell will last but for a certain time, after which the body and soul will be destroyed. And, 4. That it is not lawful for princes to make war. These four tenets were what Socinus defended with the greatest zeal. In other matters, he was a Lutheran or a Calvinist; and the truth is, that he did but refine upon the errors of all the antitrinitarians that went before him.

SOCOTORA, an island in the Indian ocean, about seventy miles long, and fifty broad: situate in E. long. 53°, N. lat. 11°.

SOCRATIC PHILOSOPHY, the doctrines and opinions, with regard to morality and religion, maintained and taught by Socrates. By the character of Socrates left us by the ancients, particularly by his scholar Plato, Laertius, &c. he appears to have been one of the best and the wisest persons in all the heathen world. To him is ascribed the first introducing of moral philosophy, which is what is meant by that usual saying, "That Socrates first called philosophy down from heaven to earth;" that is, from the contemplation of the heavens and heavenly bodies, he led men to consider themselves, their own passions, opinions, faculties, duties, actions, &c. He wrote nothing himself; yet all the Grecian sects of philosophers refer their origin to his discipline, particularly the platonists, peripatetics, academics, cyrenaics, stoics, &c. but the greatest part of his philosophy we have in the works of Plato.

SODA, or HEAT of the stomach, in medicine, the name of a distemper consisting in a heat or troublesome burning about the pit of the stomach, or its left mouth, which sometimes is extended the whole length of the oesophagus, with a pressure or spasmodic constriction, usually attacking the patient by fits. See MEDICINE.

SODBURY, a market-town of Gloucestershire, situated ten miles north east of Bristol.

SODOMY, the unnatural crime of buggery, thus called from the city of Sodom, which was destroyed by fire for the same. The Levitical law adjudged those guilty of this execrable crime to death, and the civil law assigns the same punishment to it. Our law also makes it felony.

There is no statute in Scotland against sodomy; the

libel of the crime is therefore founded on the divine law, and practice makes its punishment to be burning alive.

SOFA, in the Turkish customs, a bench of wood raised from the ground about a foot high, and placed round a hall or chamber for the people to sit down upon, or to lie along, and in that posture to take a view of what passes in the streets, &c. for these benches are surrounded with windows; they are covered with fine Turkey carpets; and upon that are placed cushions of satin, flowered with gold or some other rich stuff.

SOFALEA, the capital of the territory of that name in Africa, situated at the mouth of the river Sofala, in E. long. 35° S. lat. 20°.

SOFFITA, or **SOFFIT**, in architecture, any plafond or ceiling formed of cross beams of flying corniches, the square compartments or panels of which are enriched with sculpture, painting or gilding; such are those in the palaces of Italy, and in the apartments of Luxemburg at Paris.

SOFTENING, in painting, the mixing and diluting of colours with the brush or pencil.

SOGDIANA, a country of Asia, situated on the north side of the river Oxus, which separated it from the ancient Bactria, now a part of Ussac Tartary.

SOHAM, a market-town of Cambridgeshire, situated on a lake called Soham Meer, in the Isle of Ely, fourteen miles north-east of Cambridge.

SOIL, in agriculture. See **AGRICULTURE**, p. 50.

SOISSONS, a city of France, in the province of the Isle of France, situated on the river Aysle, fifty five miles north-east of Paris.

SOL, the **SUN**, in astronomy, &c. See **ASTRONOMY**, p. 435.

SOL, in chemistry, is gold. See **CHEMISTRY**, p. 78.

SOL, in heraldry, denotes Or, the golden colour in the arms of sovereign princes.

SOLÆUS, in anatomy. See **ANATOMY**, p. 209.

SOLANUM, in botany, a genus of the pentandria monogynia class. The corolla is rotated; the anthers are very close together, opening with a double pore at the points; and the berry has two cells. There are 30 species, two of them natives of Britain, viz. the nigrum, or common nightshade; and the dulcamara, or woody nightshade.

Common nightshade is used to allay inflammations.

Some years ago, the internal use of the solanum was much recommended by some writers, in cancerous cases, foul ulcers, and scorbutic eruptions: however, later experience has found this simple to be not only of little or no efficacy in such cases, but to be attended with actual danger to the patient.

SOLAR, something belonging to the sun. See **ASTRONOMY**, p. 435.

SOLDANELLA, in botany, a genus of the pentandria monogynia class. The corolla is bell-shaped, and split into many segments. There is but one species, a native of Switzerland.

SOLDER, a metallic or mineral composition used in soldering or joining together other metals.

Solders are made of gold, silver, copper, tin, bismuth, and lead; usually observing, that in the composition there be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to

seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat. The solder used by plumbers is made of two pounds of lead to one of block-tin. Its goodness is tried by melting it, and pouring the bigness of a crown-piece upon a table; for if good, there will arise little bright shining stars therein. The solder for copper is made like that of the plumbers, only with copper and tin; for very nice works, instead of tin they sometimes use a quantity of silver. Solder for tin is made of two thirds of tin and one of lead; but where the work is anything delicate, as in organ pipes, where the juncture is scarce discernable, it is made of one part of bismuth and three parts of pewter.

SOLDERING, among mechanics, the joining and fastening together two pieces of the same metal, or of two different metals, by the fusion and application of some metallic composition on the extremities of the metals to be joined. See the last article.

To solder upon silver, brass, or iron: take silver, five penny-weight; brass, four penny-weight; melt them together for soft solder, which runs soonest. Take silver, five penny-weight; copper, three penny-weight; melt them together for hard solder. Beat the solder thin, and lay it on the place to be soldered, which must be first fitted and bound together with wire, as occasion requires; then take borax in powder, and temper it like pap, and lay it upon the solder, letting it dry; then cover it with quick coals, and blow, and it will run immediately; take it presently out of the fire, and it is done. It is to be observed, that if any thing is to be soldered in two places, which cannot well be done at one time, you must first solder with the harder solder, and then with the soft; for if it be first done with the soft, it will unsolder again before the other is soldered. Let it be observed, that if you would have the solder run about the piece that is to be soldered, you must rub such places over with chalk.

In the soldering either of gold, silver, copper, and all the metals before-mentioned, there is generally used borax in powder, and sometimes rosin. As to iron, it is sufficient that it be heated red hot, and the two extremities thus hammered together, by which means they will become incorporated into one another.

SOLDIER, a military man fitted to serve a prince or state, in consideration of a certain daily pay.

SOLE, in the manege, a nail or sort of horn under a horse's foot, which is much more tender than the other horn that incompasses the foot, and by reason of its hardness is properly called the horn or hoof.

SOLEA, in ichthyology. See **PLEURONCTES**.

SOLEÆ, among the Romans, a kind of sandals or slippers, which covered only the sole of the feet, and were bound on with thongs of leather, instead of which the women and the effeminate ones of the other sex tied them on with purple-coloured ribbons, or such as were variously adorned with gold and silver.

SOLECISM, in grammar, a false manner of speaking contrary to the use of language and the rules of grammar, either in respect of declension, conjugation, or syntax.

SOLEMNITIES OF DEEDS, in Scots law. See **WRITINGS**.

SOLEN, in zoology, a genus of insects belonging to the order.

order of *vermes testacea*. The shell is oblong, bivalved, and opening at both sides; the cardo has a tubulated reflected tooth, not inserted into the opposite valve. There are eleven species, distinguished by peculiarities in their shells.

SOLFAGING, in music, the naming or pronouncing the several notes of a song by the syllables *ut, re, mi, fa, sol*, &c. and in learning to sing it. See **MUSIC**.

SOLICITOR, a person employed to take care of, and manage suits depending in the courts of law or equity.

There is also a great officer of the law, next to the attorney-general, who is styled the king's solicitor-general; who holds his office by patent, during the king's pleasure has the care and concern of managing the king's affairs, and has fees for pleading, besides other fees arising by patents, &c. He hath his attendance on the privy-council; and the attorney-general and he were anciently reckoned among the officers of the exchequer; they have their audience, and come within the bar in all other courts.

SOLID, a body whose parts are so firmly connected together, as not to give way, or slip from each other upon the smallest impression; in which sense, solid stands opposed to fluid.

SOLIDAGO, in botany, a genus of the *syngenesia polygamia superflua* class. The receptacle is naked; the pappus is simple; the calix is imbricated with that scales. There are twelve species, two of them natives of Britain. *viz.* the *virgaurea*, or common golden rod; and the *cambrica*, or Welch golden rod.

SOLIDITY, that property of matter, or body, by which it excludes all other bodies from that place which itself possesses. See **METAPHYSICS**.

SOLILOQUY, a reasoning or discourse which a man holds with himself, or, more properly, according to Papias, it is a discourse by way of answer to a question that a man proposes to himself.

Soliloquies are become very common things on the modern stage; yet can nothing be more unnatural, than an actor's making long speeches to himself, to convey his intentions to the audience. Where such discoveries are necessary to be made, the poet should rather take care to give the dramatic persons such confidants as may necessarily share their inmost thoughts, by which means they may be more naturally conveyed to the audience: yet is even this a shift an accurate poet would not be found to have occasion for.

SOLITARY, something retired or in private, remote from the company or commerce of others of the same species.

SOLITARIES, a denomination of nuns of St. Peter of Alcantara, instituted in 1576, the design of which is to imitate the severe penitent life of that saint: thus they are to keep a continual silence, never to open their mouths to any body but themselves; employ their time wholly in spiritual exercises, and leave the temporal concerns to a number of maids, who have a particular superior in a separate part of the monastery. They always go bare footed, without sandals, gird themselves with a thick cord, and wear no linen.

SOLMS, the capital of the county of Solms, in the landgraviate of Hesse-Cassel, in Germany, thirty-five miles north of Frankfurt.

SOLO, in music, a term used in pieces consisting of se-

veral parts, to mark those that are to perform alone. **SOLOMON'S ISLANDS**, a cluster of islands in the Pacific ocean, situated between 130° and 140° W. long. and between 7° and 12° S. lat.

SOLOMON'S SEAL, in botany. See **CONVALLARIA**.

SOLOTHURN, one of the cantons of Switzerland, lying between those of Basile and Bern, the former on the north, and the latter on the south.

The city of Solothurn, capital of the said canton, is situated in E. long 7° 15', and N. lat. 47° 18'.

SOLSTICE, in astronomy, that time when the sun is in one of the solstitial points; that is, when he is at his greatest distance from the equator. See **ASTRONOMY**.

SOLVENT, the same with dissolvent. See **DISSOLVENT**.

SOLUTION, in chemistry, denotes an intimate mixture of solid bodies with fluids, so as seemingly to form one homogeneous liquor; the dissolving fluid is termed the dissolvent or menstruum. See **CHEMISTRY**, *passim*.

SOMERSETSHIRE, a county of England, situated on the Bristol channel, and bounded by Wiltshire on the east, by Dorsetshire on the south, and by Devonshire on the west: it is famous for the cloth manufacture.

SOMERTON, a market-town of Somersetshire, twelve miles south of Wales.

SOMME, a river of France, which running from east to west through Picardy, by Amiens and Abbeville, falls into the British channel near St. Vallery.

SOMNAMBULI, in medicine, persons who walk in their sleep, otherwise called noctambuli.

SON, an appellation given to a male child, considered in the relation he bears to his parents.

SONATA, in music, a piece, or composition, intended to be performed by instruments only; in which sense, it stands opposed to cantata, or a piece designed for the voice.

SONCHUS, the *LOW-THISTLE*, in botany, a genus of the *syngenesia polygamia æqualis* class. The receptacle is naked; the calix is imbricated, and ventricose; and the pappus is plumose. There are ten species, three of them natives of Britain. *viz.* the oleaceus, or common low-thistle; the arvensis, or tree low-thistle; and the palustris, or marsh low-thistle.

Sonchus is accounted cooling and attenuant, and accordingly prescribed in the stranguries, as also in inflammations of all kinds, to be applied externally in the form of a cataplasm.

SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung.

SONG, in music, is applied in general to a single piece of music, whether contrived for the voice or an instrument.

SONNA, a book of Mahometan traditions, wherein all the orthodox muselmenn are required to believe.

SONNET, in poetry, a composition contained in fourteen verses, *viz.* two stanzas, or measures, of four verses each; and two of three; the eight first verses being all in three rhimes.

SONNETS, among the Mahometans, an appellation given to the orthodox muselmenn, or true believers; in opposition to the several heretical sects, particularly the schiites, or followers of Ali.

SOOT, a volatile matter, arising from wood, and other fuel, along with the smoke; or rather, it is the smoke itself, fixed and gathered on the sides of the chimney.

See **CHEMISTRY**, p. 153. and **AGRICULTURE**, p. 49.

SOPH,

SOPHI, a title given to the emperor of Persia; importing as much as wise, sage, or philosopher. There is no prince in the world whose authority is more absolute than that of the sphi of Persia.

SOPHISM, in logic, &c. an argument which carries much of the appearance of truth, and yet leads into error.

SOPHIST, a person who uses sophisms, with a view to deceive those he would persuade or convince.

SOPHISTICATIOn, the adulterating any thing with what is not good or genuine; a practice too common in the making up medicines for sale; as also among vintners, distillers, and others, who are accused of sophisticating their wines, spirits, oils, &c. by mixing with them cheaper and coarser materials: and; in many cases, the cheat is carried on so artfully as to deceive the best judges.

SOPHORA, in botany, a genus of the decandria monogynia class. The calix has five teeth, and is gibbous above; the corolla is papilionaceous, with the wings of the same length as the vexillum; and the capsule is a legumen. There are eight species, none of them natives of Britain.

SOPORIFIC MEDICINES, are those capable of procuring sleep, as opiates, &c. See **OPIATES**, &c.

SORBONNE, the house or college of the faculty of theology, in the university of Paris; sometimes also used for the faculty itself, because it usually assembles in the house of the sorbonne.

SORBUS, in botany, a genus of the icofandria trigynia class. The calix consists of five leaves, and the corolla of five petals; and the berry contains three seeds. There are three species, two of them natives of Britain, viz. the domestica, or the true service or sorb; and the aucuparia, quicken-tree, or mountain-ash.

SORCERY, the crime of witchcraft or divination by the assistance of an evil spirit. See **WITCHCRAFT**.

SORET, a province of the Hither India, lying northwards of Guzerat: its chief town is Jaganat.

SOREX, in zoology. See **Mus**.

SORITES, in logic, a species of reasoning, in which a great number of propositions are so linked together, that the predicate of the one becomes continually the subject of the next following, till at last a conclusion is formed by bringing together the subject of the first proposition and the predicate of the last. See **LOGIC**.

SORNERS, in Scots law. See **LAW**, Tit. xxxiii. 30.

SORREL, in botany. See **RUMEX**.

Wood SORREL, in botany. See **OXALIS**.

SORREL COLOUR, in the menage, is a reddish colour, generally thought to be a sign of a good horse.

SORRENTO, a city and port-town of the kingdom of Naples, eighteen miles south of that city.

SORTILEGE, a species of divination, performed by means of sortes or lots.

The sortes prenestinae, famous in antiquity, consisted in putting a number of letters, or even whole words, into an urn; and then, after shaking them together, they were thrown on the ground, and whatever sentences could be made out from them constituted the answer of the oracle.

Another kind of sortes consisted in taking some celebrated poet, as Homer or Virgil; and, opening the book, whatever presented itself first to the eye made the answer; and hence it got the name of sortes homericæ, and sortes virgilianæ, &c.

The superstitious among the ancient Christians practised a similar kind of divination, by opening the Old and New Testament; whence it got the name of sortes sanctorum.

SOTERIA, in antiquity, sacrifices offered to the gods for delivering a person from danger; as also poetical pieces composed for the same purpose.

SOTOVENTO ISLANDS are situated on the coast of Terra-Firma; the chief of which are Trinidad, Margareta, Tortuga, &c. They are also called the Lesser Antilles.

SOUBISE, a town of Guienne, in France, situated on the river Charente, seventeen miles south of Rochelle.

SOUGH, among miners, denotes a passage dug under ground, to convey off water from mines.

SOVEREIGN, in matters of government, is applied to the supreme magistrate, or magistrates, of an independent government or state; by reason their authority is only bounded by the laws of God, of nature, and the fundamental laws of the state: such are kings, princes, &c.

SOUL, a spiritual substance, which animates the bodies of living creatures: it is the principle of life and activity within them.

Various have been the opinions of philosophers concerning the substance of the human soul. The Cartesians make thinking the essence of the soul. Others again hold, that man is endowed with three kinds of souls, viz. the rational, which is purely spiritual, and infused by the immediate inspiration of God; the irrational, or sensitive, which is common to man and brutes; and lastly, the vegetative soul, or principle of growth and nutrition.

That the soul is an immaterial substance appears from hence, that its primary operations of willing and thinking have not only no connection with the known properties of body, but seem plainly inconsistent with some of its most essential qualities. For the mind discovers no relation between thinking and the motion and arrangement of parts.

As to the immortality of the human soul, the arguments to prove it may be reduced to the following heads: 1. The nature of the soul itself, its desires, sense of moral good and evil, gradual increase in knowledge and perfection, &c. 2. The moral attributes of God.

Under the former of these heads it is urged, that the soul, being an immaterial intelligent substance, does not depend on the body for its existence; and therefore may, nay, and must, exist after the dissolution of the body, unless annihilated by the same power which gave it a being at first. This argument, especially if the infinite capacity of the soul, its strong desire after immortality, its rational activity and advancement towards perfection, be likewise considered, will appear perfectly conclusive to men of a philosophical turn; because nature, or rather the God of nature, does nothing in vain.

But arguments drawn from the latter head, viz. the moral attributes of the Deity, are not only better adapted to convince men unacquainted with abstract reasoning, but equally certain and conclusive with the former: for as the justice of God can never suffer the wicked to escape unpunished, nor the good to remain always unrewarded; therefore, arguments drawn from the manifest and constant prosperity of the wicked, and the frequent unhappiness of good men in this life, must convince every thinking person, that there is a future state wherein all will

will be set right, and God's attributes of wisdom, justice, and goodness, fully vindicated. We shall only add, that had the virtuous and conscientious part of mankind no hopes of a future state, they would be of all men most miserable: but as this is absolutely inconsistent with the moral character of the Deity, the certainty of such a state is clear to a demonstration.

SOUND, a simple perception, or idea, communicated to the soul, by means of the ear, which is the primary organ of hearing. See *ANATOMY*, p. 295. and *PNEUMATICS*, p. 488.

SOUND, in geography, denotes in general any freight, or inlet, of the sea, between two head-lands. However, the name sound is given, by way of eminence, to the freight between Sweden and Denmark, joining the German ocean to the Baltic, being about four miles over.

SOUNDING, in navigation, is the trying the depth of the water, and the quality of the bottom, either by an inch or three-quarter rope, with a deep sea-lead at the end of it. See *NAVIGATION*.

SOUP, a kind of pottage made of bread and broth, or the juice of flesh, or some other matters, usually served at the beginning of a meal.

SOURIS, in the manege, is a cartilage in the nostrils of a horse, by means of which he snorts.

SOUTH, one of the four cardinal points from which the winds blow. See *NAVIGATION*, and *PNEUMATICS*.

SOUTHAM, a market-town of Warwickshire, situated seven miles south-east of Warwick.

SOUTHAMPTON, a borough and port town of Hampshire, situated on a bay of the English channel, twelve miles south-west of Winchester. It sends two members to parliament.

SOUTHERN-WOOD, in botany. See *ARTEMISIA*.

SOUTHMOULTON, a market-town of Devonshire, situated twenty-four miles north-west of Exeter.

SOUTHPETHERTON, a market-town of Somersetshire, situated twenty-two miles south of Wells.

SOUTHWARK, a borough of Surry, and a suburb to London, with which it has a communication by a magnificent bridge. It is situated on the south side of the Thames, and sends two members to parliament.

SOUTHWELL, a market-town of Nottinghamshire, situated eight miles north-east of Nottingham.

SOUTHWOLD, a port-town of Suffolk, situated on a bay of the German Sea, forty-two miles east of Bury.

SOUVIGNY, a town of France, in the province of Lyons, and territory of Bourbonnois, situated fifty miles south-east of Bourges.

SOW, in zoology. See *Sus*.

Sow, in the iron-works, the name of the block or lump of metal they work at once in the iron furnace.

SOWING, in agriculture. See *AGRICULTURE*, p. 59.

SPAW, a town of Germany, in the circle of Westphalia, and bishopric of Liege, situated seventeen miles south-east of Liege, famous for its mineral waters ever since the time of the Romans, of which there are still great quantities sent abroad to all parts of Europe.

Spaw waters are the lightest and most subtle of all the mineral waters. One very remarkable virtue of this water is, that it greatly relieves in all disorders of the kidneys, ureters, and bladder, whether occasioned by stone, gravel, or ulcerations. It possesses, beside, all the vir-

tues of the other mineral waters, and is of the greatest service in edulcorating sharp, and dividing viscous humours, and removing all diseases arising from these causes, by disposing them to pass off by proper emunctories.

SPACE is defined by Mr Locke to be a simple idea which we attain both by our sight and touch; the modes whereof are distance, capacity, extension, duration, &c. See *METAPHYSICS*.

SPACE, in geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

SPAGIRIC ART, a name given by authors to that species of chemistry which works on the metals, and is employed in the search of the philosopher's stone.

SPAHIS; horsemen in the Ottoman army, chiefly raised in Asia. The great strength of the grand seignior's army consists in the janizaries who are the foot, and the spahis, who are the horse.

SPAIN, including Portugal, is a large peninsula of Europe, lying between 10° west and 3° east longitude, and between 30° and 44° north latitude, being about seven hundred miles in length from east to west, and about five hundred in breadth from north to south: it is bounded by the bay of Biscay, on the north; by the Pyrenean mountains, which separate it from France, on the north-east; by the Mediterranean sea, on the south-east; and by the Atlantic ocean, on the west.

New Spain. See *MEXICO*.

SPALATRO, a city and port-town of Dalmatia, situated on the gulph of Venice: E. long. 17° 45', N. lat. 45° 16'.

SPALDING, a market-town of Lincolnshire, situated under the meridian of London, thirty miles south-east of Lincoln.

SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out. The span is estimated at three hand's breadths, or nine inches.

SPANDAW, a town of Germany, in the circle of Upper Saxony, and Marquisate of Brandenburg, situated on the river Havel, eight miles north-west of Berlin.

SPANIEL, in zoology. See *CANIS*.

SPAR, in natural history, a class of fossils, not inflammable nor soluble in water; when pure, it is pellucid and colourless, and emulating the appearance of crystal, but wanting its distinguishing characters; composed of plane and equable plates, not flexible nor elastic, not giving fire with steel, readily calcining in a small fire, and fermenting violently with acids, and wholly soluble in them.

The spars, in general, are found in the fissures of stones, and about mines. Derbyshire affords enough of them to supply the whole world; and the German mines afford yet larger quantities.

SPARADRAPUM, in pharmacy, &c. a sort of cere-dloth, called also *vela Gualteri*, the form whereof is directed as follows. Take of the diapalma plaister, and diachylon with the gums, each one pound; cerufs, half a pound; root of oris finely powdered, an ounce and a half. Mix these together; and whilst they are in fusion, dip them in soft worn-out linen-rags, so that they may be covered with the plaister on each side; then take them out, spread them, and let them dry; and smoothe the surfaces with

a knife or spatula. The principal use of these is for issues. **SPARGANIUM**, in botany, a genus of the monœcia triandria class. The amentum of both male and female is roundish; and the calix of both consists of three leaves; neither of them have any corolla; the stigma of the female is bifid; and the drupa is dry, and contains two seeds. There are two species, both natives of Britain, viz. the crestum, or great-bur-reed; and the natans, or least bur-reed.

SPARROW, in ornithology. See **FRINGILLA**.

SPARROW-HAWK, in ornithology. See **FALCO**.

SPARTIUM, in botany, a genus of the diadelphia decandria class. The stigma is longitudinal, and downy above; the filaments adhere to the carina; and the calix is longest on the back part. There are 10 species, only one of them, viz. the scoparium, or common broom, a native of Britain.

SPARTIVENTO CAPE, the most southern point or promontory of Italy: situated in E. long. 16° 30', N. lat. 38° 20'.

SPARUS, in ichthyology, a genus belonging to the order of thoracici. The fore-teeth and dog-teeth are very strong; the grinders are obtuse, and thick set; the lips are folded over; there are five rays in the gill-membrane, and the opercula are scaly; the body is compressed; the lateral line is crooked behind; and the pectoral fins are roundish. There are 26 species.

SPASM, in medicine, a convulsion.

A spasm, according to Hoffman, may be universal or particular, salutary or morbid. An universal spasm happens if the whole vascular genus, chiefly the heart and arteries, as also the fibres of the system, are affected, and there is a preternatural constriction therein, whereby the systole and diastole are increased, and the progress of the blood accelerated; this constitutes a fever, whereof a frequent pulse is the most certain sign. See **MEDICINE**.

SPASMODIC, something belonging to a spasm or convulsion. See the last article.

SPATHA, in botany. See **BOTANY**, p. 636.

SPAVIN, in the manege, a disease in horses, being a swelling or stiffness, usually in the ham, occasioning a lameness. See **FARRIERY**, p. 572.

SPAYING, or **SPADING**, the operation of castrating the females of several kinds of animals, as sows, bitches, &c. to prevent any further conception, and promote their fattening.

It is performed by cutting them in the mid flank, on the left side, with a sharp knife or lancet, taking out the uterus and cutting it off, and so stitching up the wound, anointing the part with tar, and keeping the animal warm for two or three days. The usual way is to make the incision above two inches and a half long, that the forefinger may be put in towards the back to feel for the ovaries, which are two kernels as big as acorns on both sides of the uterus, one of which is drawn to the wound, the string thereof cut, and thus both taken out.

SPEAKER of the house of commons, a member of the house, elected by a majority of the votes thereof, to act as chairman or president in putting questions, reading briefs or bills, keeping order, reprimanding the refractory, adjourning the house, &c. See **PARLIAMENT**.

SPEAKING, the art or act of expressing one's thoughts in articulate sounds or words.

SPECIAL, something that is particular, or has a particular designation; from the Latin *species*, in opposition to general from *genus*.

SPECIES, in logic, a relative term, expressing an idea which is comprised under some general one called a genus, See **LOGIC** and **METAPHYSICS**.

SPECIES, in optics, the image painted on the retina, by the rays of light reflected from the several points of the surface of an object.

SPECIES, in commerce, are the several pieces of gold, silver, copper, &c. which having passed their full preparation and coinage are current in public. See **MONEY**.

SPECIFIC, in philosophy, that which is peculiar to any thing, and distinguishes it from all others.

SPECIFIC, in medicine, a remedy whose virtue and effect is peculiarly adapted to some certain disease, is adequate thereto, and exerts its whole force immediately thereon.

SPECIFICATION, in Scots law. See **LAW**, Tit. viii. 7.

SPECTACLES, in dioptrics, a machine consisting of two lenses, set in silver, horn, &c. to assist the defects of the organ of sight.

Old people, and others who have flat eyes, use convex spectacles, which cause the rays of light to converge so as to fall upon the retina: whereas myopes, or short-sighted persons, use concave lenses for spectacles, which causing the rays to diverge, prevent their meeting ere they reach the retina. See **OPTICS**.

SPECULARIS LAPIS, in natural history, a genus of talcs composed of large plates visibly separate, and of extreme thinness; and each fissile again separated into a number of plates still finer.

Of this genus there are three species. 1. The white shining specularis, with large and broad leaves, commonly calledising-glass and Mulcovy glass: its lamellæ, or leaves, are extremely thin, elastic, and transparent; it makes not the least effervescence with aqua-fortis, and is not easily calcined in the fire. It is imported in great quantities: the miniature painters cover their pictures with it; the lantern-makers sometimes use it instead of horn; and minute objects are usually preferred between two plates of it, for examination by the microscope. 2. The bright brown specularis, with broad leaves; a very valuable species, though inferior to the former. 3. The purple bright specularis, with broad leaves; which is the most elegant of all the talcs, and not less beautifully transparent than the first kind.

SPECULATIVE, something relating to the theory of some art or science, in contradistinction to practical.

SPECULUM, a looking glass, or mirror, capable of reflecting the rays of the sun. &c. See **OPTICS**.

SPECULUM, in surgery, an instrument for dilating a wound, or the like, in order to examine it attentively. See **SURGERY**.

SPEECH, in general, the art or act of expressing a person's thoughts, by means of articulate sounds, which we call words. See **LANGUAGE** and **GRAMMAR**.

SPEEDWELL, in botany. See **VERONICA**.

SPELL, in general, denotes the same with charm or amulet. See **CHARM** and **AMULET**.

SPELLING, in grammar, that part of orthography which teaches.

teaches the true manner of resolving words into their syllables. See GRAMMAR.

SPERGULA, in botany, a genus of the decandria pentagynia class. The calix consists of five leaves, and the corolla of five entire petals; the capsule is oval, with one cell and five valves. There are five species, three of them natives of Britain, viz. the arvensis, or corn-spurrey; the pentandria, or small spurrey; and the nodosa, or knotted spurrey.

SPERM. See SEED.

SPERMA-CETI, a white flaky substance, prepared from the oil of a species of whale, called physter macrocephalus. See PHYSETER.

SPERMACOCE, in botany, a genus of the tetrandria monogynia class. The corolla consists of one funnel-shaped petal; and it has two bidentated seeds. There are six species, none of them natives of Britain.

SPERMATIC, in anatomy, something belonging to the sperm or seed. See ANATOMY, p. 270.

SPEY, a river of Scotland, which, running north-east, through Badenoch and Murray, falls into the German fæ, east of the frith of Murray.

SPHACELUS, in surgery and medicine, an absolute and perfect corruption or death of the parts. See MEDICINE and SURGERY.

SPHÆRANTHUS, in botany, a genus of the syngenesia polygamia fæggregata class. The receptacle is naked; it has no pappus; the calix is imbricated. There are two species, none of them natives of Britain.

SPHAGNUM, in botany, a genus of the cryptogamia muscorum class. The anthers are operculated, and there is no calyx. The species are three, all natives of Britain, viz. the palustre, or grey bog-moss; the alpinum, or mountain bog-moss; and the arboreum, or creeping bog-moss.

S. SPHENOIDES, in anatomy. See ANATOMY, p. 158.

SPHERE, is a solid contained under one uniform round surface, such as would be formed by the revolution of a circle about a diameter thereof, as an axis. See GEOMETRY, and ASTRONOMY.

SPHEROID, in geometry, a solid, approaching to the figure of a sphere.

The spheroid is generated by the entire revolution of a semi-ellipsis about its axis.

SPHINCTER, in anatomy, a term applied to a kind of circular muscles, or muscles in form of rings, which serve to close and draw up several orifices of the body, and prevent the excretion of the contents.

SPHINX, in sculpture, &c. a figure or representation of a monster of that name, famed among the ancients, now mostly used as an ornament in gardens, terraces, &c. It is represented with the head and breasts of a woman, the wings of a bird, the claws of a lion, and the rest of the body like a dog.

SPICA VIRGINIS, a star of the first magnitude, in the constellation virgo. See ASTRONOMY, p. 487.

SPICE, any kind of aromatic drug that has hot and pungent qualities: such are pepper, nutmeg, ginger, cinnamon, cloves, &c.

SPICE-ISLANDS situated in the East-Indies. See BANDA, M-LUCCA-ISLANDS. and CEYLON.

SPIDER, in zoology. See ARANEÆ.

SPIDER-WORT, in botany. See PHALANGIUM.

SPIEL, in the glass-trade, an iron instrument, hooked at the end, and pointed, with which the workmen take the metal up out of the melting-pots, for proofs or essays, to see whether it be fit for work.

SPIGELBURG, a town of Germany, in the circle of Westphalia, capital of the county of Spigelsburg: E. long. 6° 25', N. lat. 52° 6'.

SPIGELIA, in botany, a genus of the pentandria monogynia class. The corolla is funnel shaped; and the capsule has two cells, and containing many seeds.

SPIKE, or oil of SPIKE, a name given to an essential oil distilled from lavender, and much used by the varnish-makers and the painters in enamel.

SPIKENARD, in botany. See NARDUS.

Ploughman's SPIKENARD, in botany. See CONYZA.

SPIILIMBERGO, a town of Italy, in the territory of Venice, and province of Friuli: situated forty-five miles north of Venice.

SPILSBY, a market-town of Lincolnshire: situated twenty-seven miles east of Lincoln.

SPINA VENTROSA, in surgery, that species of corruption of the bones which takes its rise in the internal parts, and by degrees enlarges the bone, and raises it into a tumour, See SURGERY.

SPINACHIA, in botany, a genus of the diœcia pentandria class. The calix of the male consists of five segments, and that of the female of four; neither of them have any corolla; the stili are four; and there is one hard seed within the calix. The species are two, none of them natives of Britain.

SPINAL MARROW. See ANATOMY, p. 288.

SPINALIS in anatomy, the names of several muscles, &c. See ANATOMY, p. 195. &c.

SPINE, *SPINA DORSI*, in anatomy. See ANATOMY, p. 166.

SPINET, or **SPINNET**, a musical instrument, ranked in the second or third place among harmonious instruments.

SPINNING, the act or art of reducing silk, flax, hemp, wool, hair, or other matters, into thread. Spinning is either performed on the wheel with a distaff and spindle, or with other machines proper for the several kinds of working. Hemp, flax, nettle-thread, and the like vegetable matters, are to be wetted in spinning; silks, wools, &c. are to be spun dry, and do not need water; but there is a way of spinning silk as it comes off the cafes or balls, where hot and even boiling water is to be used.

SPINOZISM, the doctrine of Spinoza, or atheism and pantheism proposed after the manner of Spinoza, who was born a Jew at Amsterdam.

The great principles of Spinozism, is, that there is nothing properly and absolutely existing besides matter and the modifications of matter; among which are even comprehended thought, abstract and general ideas, comparisons, relations, combinations of relations, &c.

The chief articles in Spinoza's system are reducible to these. That there is but one substance in nature; and that this only substance is endued with an infinite number of attributes, among which are extension and cogitation: that all the bodies in the universe are modifications of this substance considered as it is extended; and that all the souls of men are modifications of the same substance considered as cogitative: that God is a necessary and infinitely perfect Being, and is the cause of all things that exist,

exist, but not a different being from them : that there is but one being and one nature, and that this nature produces within itself, by an immanent act, all those which we call creatures ; and that this being is at the same time both agent and patient, efficient cause and subject, but that he produces nothing but modifications of himself.

SPIRÆA, in botany, a genus of the icofandria pentagynia class. The calix consists of five segments, and the corolla of five petals; and the capsule contains many seeds. There are eleven species, none of them natives of Britain.

SPIRAL, in geometry, a curve line of the circular kind, which, in its progress, recedes from its center.

SPIRAL, in architecture and sculpture, implies a curve that ascends, winding about a cone or spire, so as all the points thereof continually approach the axis. It is distinguished from the helix, by its winding around a cone, whereas the helix winds in the same manner around a cylinder.

SPIRE, in architecture, was used by the ancients for the bafe of a column, and sometimes for the atragal or tore. But among the moderns, it denotes a steeple that continually diminishes as it ascends, whether conically or pyramidally.

SPIRE, in geography, an imperial city of Germany, capital of a bishopric of the same name, and situated in the palatinate of the Rhine, fifteen miles south west of Heidelberg: E. long. 8° 17'; N. lat. 49° 16'.

SPIRIT, in metaphysics, an incorporeal being or intelligence ; in which sense, God is said to be a spirit, as are angels and the human soul.

SPIRITS, or **ANIMAL SPIRITS**, in physiology. See **ANATOMY**, p. 253, and **ÆTHER**.

SPIRIT, in chemistry, a name applied to several very different substances. However, in general, it denotes any distilled volatill liquor that is not inspid, as phlegm, or pure water, not inflammable as oil : but under this general idea are comprehended liquors of quite opposite natures, some being acid, and others alkaline; which last are such enemies to the former, that as soon as they are put together, they raise a violent effervescence, and grow hot : and to these may be added a third sort, called vinous or inflammable spirits ; which, though very subtle or penetrating, are not manifestly either acid or alkaline. See **CHEMISTRY**, p. 69, 95, 161, &c.

SPIRITUAL, in general, something belonging to, or partaking of, the nature of spirit. See **SPIRIT**.

SPIRITUALITIES of a bishop, are the profits he receives as a bishop, and not as a baron of parliament : such are the duties of his visitation, presentation money, what arises from the ordination and institution of priests, the income of his jurisdiction, &c.

SPITHEAD, a road between Portsmouth and the isle of Wight, where the Royal navy of Great Britain frequently rendezvous

SPITTLE, in physiology. See **SALIVA**.

SPITZBERGEN. See **GROENLAND**.

SPLACHNUM, in botany, a genus of the cryptogamia musci class. The calix of the male flower is a smooth conic calyptra; the antheræ are cylindric; and the receptacle coloured, membranaceous, and very large. There are four species, only one of them, viz. the ampullaceum, or common splachnum, a native of Britain.

SPLEEN, in anatomy. See **ANATOMY**, p. 266.

SPLEEN-WORT. See **ASPLENIUM**.

SPLENETIC, a person affected with obstruction of the spleen.

SPLENIUS, in anatomy. See **ANATOMY**, p. 216.

SPLINT, or **SPLINT**, among farriers, a callous, insensible excrescence, breeding on the shank-bone of horses. See **FARRIERY**, p. 573.

SPLICING, in the sea-language, is the untwisting the ends of two cables or ropes, and working the several strands into one another by a fidd, so that they become as strong as if they were but one rope.

SPODIUM, in pharmacy, one of the foulest recrements of copper.

SPOILS, whatever is taken from the enemy in time of war.

Among the ancient Greeks, the spoils were divided in common among the whole army; only the general's share was largest : but among the Romans, the spoils belonged to the republic.

SPOLETTO, the capital of Umbria, in Italy : it is situated fifty miles north-east of Rome.

SPONDEE, in ancient poetry, a foot consisting of two long syllables; as, *omnes*.

SPONDIAS, in botany, a genus of the decandria pentagynia class. The calix has five teeth, and the corolla five petals; and the drupa has five cells. There are two species, both natives of America.

SPONGIA, in zoology, a genus belonging to the order of vermes zoophyta. The whole texture is a congeries of bibulous cells. There are six species, all found in the bottom of the sea, and submarine rocks. Sponges are much used by surgeons, and others, for sucking up superfluous moisture ; which they easily part with by persure.

SPONSORS, among Christians, are those persons, who, in the office of baptism, answer or are sureties for the persons baptized.

SPONTANEOUS, a term applied to such motions of the body, and operations of the mind, as we perform of ourselves, without any constraint.

SPOON-BILL, in ornithology. See **PLATEA**.

SPOONING, in the sea-language, is said of a ship, which, being under sail in a storm at sea, is unable to bear it, and consequently forced to put right before the wind.

SPORADES, among ancient astronomers, a name given to such stars as were not included in any constellation.

SPORADIC DISEASES, among physicians, are such as seize particular persons at any time or season, and in any place ; in which sense they are distinguished from epidemic and endemic diseases.

SPOTS, in astronomy, certain places of the sun's or moon's disc, observed to be either more bright, or darker, than the rest ; and accordingly, called *fæculæ* and *maculæ*. See **ASTRONOMY**.

SPOUT, or **WATER-SPOUT**, an extraordinary and dangerous meteor, observed at sea, and sometimes at land, called by the Latins *typho* and *sipho*. Its first appearance is in form of a deep cloud, the upper part of which is white, and the lower black : then from the lower part of this cloud hangs, or rather falls down, what is properly called the spout, in form of a conical tube, biggest at top ; and under this tube, there is always a great boiling,

boiling and flying up of the water of the sea, as in a *jet d'eau*. For some yards above the surface of the sea, the water stands as a column or pillar, from the extremity whereof it spreads and goes off, as in a kind of smoke. Frequently, the cone descends so low, as to touch the middle of this column, and continue for some time contiguous to it; though sometimes it only points to it, at some distance, either in a perpendicular or oblique line. Frequently it is scarce distinguishable whether the cone or the column appear the first, both appearing all of a sudden against each other. But sometimes the water boils up from the sea to a great height, without any appearance of a spout pointing to it, either perpendicularly or obliquely. Indeed, generally, the boiling or flying up of the water has the priority, this always preceding its being formed into a column. Generally, the cone does not appear hollow, till towards the end, when the sea-water is violently thrown up along its middle, as smoke up a chimney. Soon after this, the spout or canal breaks and disappears: the boiling up of the water, and even the pillar, continuing to the last, and for some time afterwards; sometimes till the spout form itself again, and appear anew; which it sometimes does several times in a quarter of an hour.

M. de la Pyme, from a near observation of two or three spouts in Yorkshire, described in the Philosophical Transactions, gathers, that the water-spout is nothing but a gyration of clouds by contrary winds, meeting in a point or centre; and there, where the greatest condensation and gravitation is, falling down into a pipe or great tube, somewhat like Archimedes's spiral screw; and, in its working and whirling motion, absorbing and raising the water, in the same manner as the spiral screw does; and thus destroying ships, &c.

SPRAT, in ichthyology. See CLUPEA.

SPRING, in natural history, a fountain or source of water, rising out of the ground. See HYDROSTATICS.

SPRING, in mechanics, denotes a thin piece of tempered steel, or other elastic substance; which, being wound up, serves to put several machines in motion by its elasticity, or endeavour to unbend itself: such is the spring of a clock, watch, and the like.

SPRING TIDE. See ASTRONOMY, p. 473, &c.

SPUNGE. See SPONGIA.

SPUNGING, in gunnery, the cleaning a gun's inside with a sponge, in order to prevent any sparks of fire from remaining in her, which would endanger the life of him who should load her again.

SPUN-YARN, among sailors, is a kind of line made from rope yarn, and used for seizing or fastening things together.

SPUR, a piece of metal, consisting of two branches encompassing a horseman's heel, and a rowel in form of a star, advancing out behind to prick the horse.

SPURGE, in botany. See EUPHORBIA.

SPURGE LAUREL. See DAPHNE.

SPURKE'S, in a ship, spaces between the upper and lower futtocks, or betwixt the rungs fore and aft.

SPURRY, in botany. See SPERGULA.

SPUTUM, among physicians, denotes the same with the saliva or spittle. See SALIVA.

SPY, a person hired to watch the actions, motions, &c.

of another; particularly of what passes in a camp. When a spy is discovered, he is hanged immediately.

SQUADRON, in military affairs, denotes a body of horse whose number of men is not fixed; but is usually from one to two hundred.

SQUADRON of ships, a division or part of a fleet, commanded by a vice admiral, or commodore.

SQUALUS, the SHARK KIND, in ichthyology, a genus belonging to the order of amphibia nantes. There are five spiracula, one on each side of the neck; the body is oblong, and somewhat cylindrical; and the mouth is situate in the anterior part of the head. There are 15 species, all inhabitants of the ocean.

SQUAMARIA, in botany. See LATHRÆA.

SQUAMOUS, in anatomy, an appellation given to the spinous or false sutures of the skull, because composed of squame or scales like those of fishes. See ANATOMY, p. 152.

SQUARE, in geometry, a quadrilateral figure, both equilateral and equiangular. See GEOMETRY.

SQUARE ROOT. See ARITHMETICK, p. 420.

Hollow SQUARE, in the military art, is a body of foot drawn up with an empty space in the middle for the colours, drums, and baggage: faced and covered by the pikes every way, to keep off horse.

SQUARE, an instrument consisting of two rules, or branches, fastened perpendicularly at one end of their extremes, so as to form a right angle: it is of great use in the description and mensuration of right angles, and laying down perpendiculars.

SQUATINA. See SQUALUS.

SQUILL, in botany. See SCILLA.

SQUINTING. See STRABISMUS.

SQUIRREL, in zoology. See SCIURUS.

STABLE, a place or house for horses, &c. furnished with stalls and proper apartments to contain their food, &c.

STACHYS, in botany, a genus of the didynamia gymnospermia class. The upper labium is vaulted and the inferior one reflected in the edges; the intermediate labium being largest, and emarginated; and the stamina are reflected towards the sides. There are 12 species, three of them natives of Britain, viz the germanica, or bafe horse-hound; the filvatica, or hedge-nettle; and the palustris, or clown's all-heal.

STADIUM, an ancient Greek long measure.

Stadium was also the course or career wherein the Greeks ran their races.

STADTHOLDER, the principal governor or magistrate of the United Provinces.

The stadtholder seems to be impowered, either directly or by his influence, to change both the deputies, magistrates, and officers, in every province and city. He is president in the states of every province, though he has not so much as a seat or vote in the states-general: but as he influences the states of each province to send what deputies he pleases to the states-general, he has, in effect, the appointing the persons that constitute the states-general, and may be deemed sovereign of the united provinces. The stadtholders had once a very great power. We find one of their stadtholders appointing what towns should send deputies or members to the assembly of the states of Holland: but the stadtholdership was never hereditary till now, when in the year 1747 it was made so in the family of Orange.

It is observed, that the states passed by the stadtholder's eldest son, and appointed his younger son prince Maurice of Orange their stadtholder; and at other times they have suppressed the stadtholdership entirely. The stadtholder always in the council of state, when the votes happen to be equal, has a decisive voice.

STAEHELINA, in botany, a genus of the syngenesia polygamia equalis class. The receptacle is naked; the pappus is feathered; and the calix is imbricated with scales, membranaceous, coloured, and reflected at the points. There are two species, none of them natives of Britain.

STAFF, an instrument ordinarily used to rest on in walking. The staff is also frequently used as a kind of natural weapon both of offence and defence, and for several other purposes.

STAFF, in music, five lines on which with the intermediate spaces the notes of a song or piece of music are marked.

STAFFORD, the county-town of Staffordshire, is situated nine hundred and thirty miles north-west of London. It sends two members to parliament.

STAG, in zoology. See **CERVUS**.

STAGE, in the modern drama, the place of action and representation, included between the pit and the scenes, and answering to the proscenium or pulpitum of the ancients.

STAGGERS. See **FARRIERY**, p. 352.

STAINES, a town of Middlesex, situated nineteen measured miles west of London.

STAIR-CASE, in architecture, an ascent inclosed between walls, or a ballustrade, consisting of stairs, or steps, with landing-places and rails, serving to make a communication between the several stories of a house. See **ARCHITECTURE**, p. 366.

STALACTITE, in natural history, crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various crusts and usually found hanging in form of icicles from the roofs of grottos, &c.

STALBRIDGE, a market-town of Dorsetshire, situated eighteen miles north of Dorchester.

STALK, in botany, that part of a plant which rises immediately from the root, and which supports the leaves of the flowers and the fruit.

STALLION, or **STONE-HORSE**, in the menage, an ungent horse, designed for the covering of mares, in order to propagate the species. See **EQUUS**.

STAMFORD, a borough-town of Lincolnshire, situated thirty-five miles south of Lincoln. It sends two members to parliament.

STAMINA. See **BOTANY**, p. 635.

STAMINA, in the animal body, are defined to be these simple original parts, which existed first in the embryo, or even in the seed; and by whose distinction, augmentation, and accretion, by additional juices, the animal body, at its utmost bulk, is supposed to be formed.

STAMINEOUS, in botany, a term for those flowers of plants which have no petals or flower-leaves, but consist only of a number of stamina and pistils placed in a cup.

STAMP-DUTIES, certain impositions laid on all parchment and paper, on which deeds, grants, or other instruments, or any process in law or equity, are ingrossed or written. These duties, when first granted, were from forty shillings

for letters-patent, &c. to sixpence for the usual deeds; and one penny for declarations, pleadings, &c. They have been, in general, doubled and trebled, by subsequent statutes; and the common stamp now is the treble sixpenny. Persons writing or engrossing any thing charged with the duty on parchment or paper, before it is stamped, or if it be marked with any lower duty than what is required, are liable to forfeit 5*l.*; and the deed shall not be deemed good in law, till such penalty is paid, and the same be stamped, &c.

STAMPALIA, an island of the Archipelago, about fifty miles in circumference, situated in E. long. 26° 30', and N. lat. 36° 20'.

STANCHION, or **STANCHIONS**, in a ship, those pillars, which being set up pillar-wise, do support and strengthen the masts or the masts-trees.

STAND, in commerce, a weight, from two hundred and a half to three hundred, of pitch.

STANDARD, in war, a sort of banner, or flag, borne as a signal for the joining together of the several troops belonging to the same body. See **FLAG**, &c.

STANDARD, in commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffick. See **MONEY**.

STANDON, a town of Hertfordshire, situated under the meridian of London, and seven miles north of Hertford.

STANHOPE, a market-town of Durham, situated sixteen miles west of Durham.

STANLEY, a town of Gloucestershire, situated twelve miles south of Gloucester.

STANNARIES, the mines and works where tin is dug and purified, as in Cornwall, Devonshire, &c. There are four courts of the stannaries in Devonshire, and as many in Cornwall; and great liberties were granted them by several acts of parliament in the time of Edward I. &c. though somewhat abridged under Edward III. and Charles I.

STANNUM, tin. See **CHEMISTRY**, p. 83, 135.

STANTON, a town of Lincolnshire, situated seventeen miles east of Lincoln, under the meridian of London.

STANZA, in poetry, a certain stated number of verses, generally containing a perfect sense, that ought to end with some lively and ingenious thought, or just and pertinent reflection.

STAPELIA, in botany, a genus of the pentandria digynia class of plants. The plant is contorted, with a double star-like nectarium covering the frutification. There are two species, both natives of the Cape of Good Hope.

STAPES, in anatomy. See **ANATOMY**, p. 296.

STAPHYLÆA; in botany, a genus of the pentandria trigynia class. The calix consists of five segments, and the corolla of five petals; the capules are inflexed and connate; and there are two globular feeds. There are two species, both natives of the Cape of Good Hope.

STAPHYLINUS in zoology, a genus of insects belonging to the order of coleoptera: the antennæ are slender; the elytra are dimidiated, and cover the wings; and the tail is simple, and furnished with two oblong bladders. There are 17 species, principally distinguished by their colour.

STAPLE primarily signifies a public place or market, whither

ther merchants. &c. are obliged to bring their goods to be bought by the people, as the Greve, or the places along the Seine, for sale of wines and corn, at Paris, whether the merchants of other parts are obliged to bring these commodities.

Formerly the merchants of England were obliged to carry their wool, cloth, lead, and other like staple-commodities of this realm, in order to utter the same by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each whereof a public mart was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way.

STAR, in astronomy. See *ASTRONOMY, passim*.

Falling STARS, in meteorology, fiery meteors, which dart through the sky, in form of a star; being occasioned by a nitro-sulphureous matter, the common cause of all such meteors.

STAR, in heraldry, a charge frequently borne on the shield, and the honourable ordinaries, in figure of a star; which differs only from the mullet, in not being pierced as this last is. See *MULLET*.

STAR, is also a badge of honour, worn by the knights of the garter, bath, and thistle. See *GARTER*.

STAR of *Bethlehem*, in botany. See *ORNITHOGALUM*.

STAR-BOARD, in the sea language, denotes the right-hand side of a ship: thus they say, star-board the helm, or helm a star board, when he that commands would have the men at the helm, or steering-wheel, put the helm to the right-side of the ship.

STAR CHAMBER, a chamber at Westminster, so called from having its roof painted with gilt stars, wherein the chancellor, assisted by others appointed for that purpose, formerly had authority to punish riots, and other misdemeanors that were not by the common law provided against.

STAR-FISH. See *ASTERIAS*.

STAR-SHOT, a gelatinous substance frequently found in fields, and supposed by the vulgar to have been produced from the meteor called a falling star; but, in reality, is the half-digested food of herons, sea-mews, and the like birds; for these birds, when shot, have been found, when dying, to disgorge a substance of the same kind.

STAR-STONE, in natural history, a name given to certain extraneous fossil stones, in form of short, and commonly somewhat crooked, columns, composed of several joints; each resembling the figure of a radiated star, with a greater or smaller number of rays in the different species: they are usually found of about an inch in length, and of the thickness of a goose-quill. Some of them have five angles, or rays, and others only four, and in some the angles are equi distant, while in others they are irregularly so; in some also they are short and blunt, while in others they are long, narrow, and pointed: and some have their angles so very short and obtuse, that at first sight they might be taken for entrochoasteria. The several joints in the same specimen are usually all of the same thickness: this however is not always the case, but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species have one of the

rays bifid; so as to emulate the appearance of a six-rayed kind.

STAR-THISTLE. See *CENTAUREA*.

STAR-WORT. See *ASTER*.

STARCH, a fecula, or sediment, found at the bottom of vessels wherein wheat has been steeped in water; of which fecula, after separating the bran from it, by passing it through sieves, they form a kind of loaves, which being dried in the sun or an oven, is afterwards cut into little pieces, and so sold. The best starch is white, soft, and friable, and easily broken into powder. Such as require fine starch do not content themselves, like the starch-men, with refuse wheat, but use the finest grain. The process is as follows: The grain being well cleaned is put to fermentation in vessels full of water, which they expose to the sun while in its greatest heat, changing the water twice a-day, for the space of eight or twelve days, according to the season. When the grain bursts easily under the finger, they judge it sufficiently fermented. The fermentation perfected, and the grain thus softened, it is put, handful by handful, into a canvas bag, to separate the flour from the husks, which is done by rubbing and beating it on a plank laid across the mouth of an empty vessel that is to receive the flour.

As the vessels are filled with this liquid flour, there is seen swimming at the top redish water, which is to be carefully skimmed off from time to time, and clean water is to be put in its place; which, after stirring the whole together, is also to be strained through a cloth or sieve, and what is left behind put into the vessel with new water, and exposed to the sun for some time. As the sediment thickens at the bottom, they drain off the water four or five times, by inclining the vessel, but without passing it through the sieve. What remains at bottom is the starch, which they cut in pieces to get out, and leave it to dry in the sun. When dry, it is laid up for use.

STARGARD, a town of Germany, in the circle of Upper-Saxony, and duchy of Pomerania, situated twenty miles east of Stetin.

STARIA, a city of Russia, in the province of Great Novogorod, situated at the south end of the Ilmen-lake: E. long $34^{\circ} 2'$, N. lat. 58° .

STARLING. See *STURNUS*.

START-POINT, a cape or promontory of Devonshire, in the English channel, twelve miles south of Dartmouth.

STATE, or ESTATE, an empire, kingdom, province, or extent of country under the same government.

STATEN ISLAND, an island of the province of New York, in North America, situated near the mouth of Hudson's river: in W. long. $72^{\circ} 31'$, N. lat. 41° .

STATERA ROMANA, or STEEL-YARD, a name given to the Roman balance.

STATES, or ESTATES, a term applied to several orders, or classes of people assembled to consult of matters for the public good.

Thus states-general is the name of an assembly consisting of the deputies of the seven United Provinces: these are usually thirty in number, some provinces sending two, others more; and whatever resolution the states-general take, must be confirmed by every province, and by every city and republic in that province, before it has the force of a law. The deputies of each province, of what number soever they be, have only one voice, and are esteemed

as but one person, the votes being given by provinces. Each province presides in the assembly in its turn, according to the order settled among them. Guelderland presides first, then Holland, &c.

States of Holland are the deputies of eighteen cities, and one representative of the nobility, constituting the states of the province of Holland: the other provinces have likewise their states, representing their sovereignty, deputies from which make what they call the states-general. In an assembly of the states of a particular province, one dissenting voice prevents their coming to any resolution.

STATICE, in botany, a genus of the pentandria trigynia class. The calix is one entire plaited leaf; the corolla consists of five petals; it has but one seed. There are 14 species, three of them natives of Britain, viz. the armeria, or sea gilly-flower; the limonium, or sea-lavender; and the reticulata, or matted sea-lavender.

STATICS, that branch of mathematics which considers the motion of bodies arising from gravity. See **HYDROSTATICS**, and **MECHANICS**.

STATION, in geometry, surveying, &c. a place pitched upon to make an observation, take an angle, or the like.

STATIONARY, in astronomy, signifies the appearance of a planet, when it seems to remain immovable on the same point of the zodiac for several days. See **АСТРОНОМЯ**.

STATIONARY-DAYS, in church-history, an appellation given to the weekly fast-days. viz. Wednesdays, and Fridays; otherwise called half-fasts, and fasts of the fourth and sixth days of the week.

These fasts are certainly as ancient as Clemens Alexandrinus and Tertullian, who both mention them; and the reason of their institution is, because on the fourth day of the week the Jews took council to put our Saviour to death, which was actually accomplished on the sixth; however, being in continual use throughout the year, they were not kept with such rigour and strictness as Lent. See the article **LENT**.

STATIVA, among the Romans, a standing camp kept for the defence of the frontiers of the empire. These camps gave rise to a great many towns, which took their names from the legion stationed there.

STATUARY, a branch of sculpture, employed in the making of statues. See **SCULPTURE**, and the next article.

Statuary is one of those arts wherein the ancients surpassed the moderns; and indeed it was much more popular, and more cultivated, among the former than the latter.

STATUE, is defined to be a piece of sculpture in full relief, representing a human figure.

Statues are formed with the chissel of several matters, as stone, marble, plaster, &c. They are also cast of various kinds of metals, particularly gold, silver, brass, and lead.

Every statue, resembling the person it is intended to represent, is called *statua iconica*. Statues acquire various other denominations. 1. Thus allegorical statue, is that which, under a human figure, or other symbol, represents something of another kind, as a part of the earth, a season, age, element, temperament, hour, &c. 2. Curule statues, are those which are represented in chariots drawn by bigge, or quadrigæ, that is, by two or four horses; of which kind there were several in the circuses, hippodromes, &c. or in cars, as we see some, with triumphal

arches, on antique medals. 3. Equestrian statue, that which represents some illustrious person on horse-back, as that famous one of Marcus Aurelius, at Rome; that of king Charles I. at Charing-cross, king George II. in Leicester-square, London; king Charles II. in the Parliament-cloze, Edinburgh; king William III. at the cross, Glasgow; &c. 4. Greek statue, denotes a figure that is naked and antique; it being in the manner the Greeks represented their deities, athletes of the olympic games, and heroes: statues of the heroes were particularly called Achillean statues, by reason of the great number of figures of that prince in most of the cities of Greece. 5. Hydraulic statue, is any figure placed as an ornament of a fountain or grotto, or that does the office of a jet d'eau, a cock, spout, or the like, by any of its parts; the like is to be understood of any animal serving for the same use. 6. Pedestrian statue, a statue standing on foot; as that of king George II. in the royal infirmary, Edinburgh; that of king Charles II. in the royal-exchange, London; and of king James II. in the privy-Gardens. 7. Roman statue, is an appellation given to such as are clothed, and which receive various names from their various dresses. Those of emperors, with long gowns over their armour, were called *statue palusate*: those of captains and cavaliers, with coats of arms, *thoracate*: those of soldiers, with cuirasses, *loricate*: those of senators and augurs, *trabeate*: those of magistrates, with long robes, *togate*: those of the people, with a plain tunic, *tunicate*: and lastly, those of the women, with long trains, *stolate*. The Romans had another division of statues into divine, which were those consecrated to the gods, as Jupiter, Mars, Apollo, &c.; Heroes, which were those of the demi-gods, as Hercules, &c.; and Augusti, which were those of the emperors, as those two of Cæsar and Augustus under the portico of the capitol. In repairing a statue cast in a mould they touch it up with a chissel, graver, or other instrument, to finish the places which have not come well off: they also clear off the barbs, and what is redundant in the joints and projections.

STATUTE, the size or height of a man.

STATUTE, in its general sense, signifies a law, ordinance, decree, &c. See **LAW**, &c.

Statute, in our laws and customs, more immediately signifies an act of parliament made by the three estates of the realm: and such statutes are either general, of which the courts at Westminster must take notice, without pleading them; or they are special and private, which last must be pleaded.

STAVANGER, a port-town of Norway, in the province of BERGEN, capital of the territory Stavanger, situated on a peninsula in the German ocean: E. long. 6° 30', N. lat. 59° 30'.

STAVEREN, a port-town of the United-Netherlands. in the province of West Friesland, situated on the Zuyder-sea: E. long. 5° 12', N. lat. 53°.

STAY, in the sea language, a big strong rope fastened to the top of one mast, and to the foot of that next before it towards the prow, serving to keep it firm, and prevent its falling aftwards or towards the poop.

STEADY, a word of command at sea, for the man at the helm to keep the ship steady in her course, and not to make angles (or yaws, as they call them) in and out.

STEATITES, in the history of fossils, a name given by late

Iate authors, to a substance called, in English, soap-earth. Dr Woodward much recommends it as a substance for making porcelain; and repeated trials of it have been made since his time, and some of them very lately; in all which it has afforded the finest earthen-ware ever made with us, and promises fair, with good management, for the equaling any in the world. It is dug in many parts of Devonshire and Cornwall, and the neighbouring counties; the cliff of the Lizard-point is almost wholly composed of it, and the adjacent little islands abound with it; and from all these places it might be brought, at a small expence, in any quantities. It is known from all other earths by these characters: it is composed of extremely fine particles; and is of a firm, equal and regular texture, and a great weight. It is very firm and hard as it lies in the earth, but when it has been some time exposed to the air, it becomes almost of a stony hardness. It is of a perfectly fine, smooth, and glossy surface, softer to the touch than any other species of earth, and does not at all adhere to the tongue, or stain the fingers in handling; but d awn along a rough surface, as a piece of cloth, or the like, it marks it with a fine and even white line. In colour it is a clear white, veined and variegated very beautifully with purple of different degrees of deepness; and is of so fine a structure of parts, that when cut into thin pieces, it is in some degree transparent. It makes no effervescence with acids, and burns to a pure white, even in its purple parts.

STEATOMA, a kind of encysted tumour, consisting of a matter like suet or lard, soft, without pain, and without discolouring the skin.

STEEL, a kind of iron refined and purified by the fire with other ingredients. See **CHEMISTRY**, p. 134.

STEEL GLASSES, a name given by some authors to the metalline spheres used in optics. These, according to Cardan, are made of three parts of brass, one part of tin, and one of silver, with an eighteenth part of antimony; but most either totally leave out the silver, or add only a twenty-fourth part, to save the expence. There are many other methods, directed by several authors; but most use arsenic and tartar mixed with the metals. These are afterwards to be polished with emery, rotten-stone, putty, and the like.

STEEL-YARD. See **MECHANICS**.

STEEPLE, an appendage erected generally on the western end of a church, to hold the bells. Steeples are deominated from their form, either spires or towers; the first are such as ascend continually diminishing either conically or pyramidically; the latter are mere parallelopipeds, and are covered a-top platform-like.

STEEAGE, on board a ship, that part of the ship next below the quarter-deck, before the bulk-head of the great cabin, where the steersman stands in most ships of war. See the next article.

STEERING, in navigation, the directing a vessel from one place to another by means of the helm and rudder. He is held the best steersman who causes the least motion in putting the helm over to and again, and who best keeps the ship from making yaws, that is, from running in and out. See **NAVIGATION**.

STEEVE, on board a ship. The seamen say the bowsprit or the beak-head of a ship steeves, when it stands too upright, or not straight enough forward.

STEGANIUM. See **SLATE**.

STEGANOGRAPHY, the art of secret writing, or of writing in cyphers known only to the persons correspond-
ing.

STEEGBURG, a port-town of Sweden, in the province of East Gothland, situated on a bay of the Baltic: *ll.* long. 16° N. lat. 58° 30'.

STEGNOTICS, in medicine, remedies proper to close and stop the orifices of the vessels or emundories when relaxed, stretched, lacerated, &c. such as pomegranate-leaves and roses, plain-tain-leaves, tormentil-roots, &c.

STELLATE, among botanists, expresses leaves which grow not less than six at a joint, and are arranged like the rays of a star.

STELLERA, in botany, a genus of the ostandria monogynia class. It has no calix, the corolla consists of four segments; the stamina are very short; and there is but one rolled stamen. There are two species, none of them natives of Britain.

STELLIONATE, in Scots law. See **LAW**, Tit. xxxiii. 36.

STEM, in botany, that part of a plant arising out of the root, and which sustains the leaves, flowers, fruits, &c.

STEM of a ship, that main piece of timber which comes bending from the keel below, where it is scarfed, as they call it; that is, pieced in; and rises compassing right before the fore-castle. This stem it is which guides the rake of the ship, and all the butt-ends of the planks are fixed into it. This, in the section of a first-rate ship, is called the main stem.

STEMPLES, in mining, cross-bars of wood in the shafts which are sunk to mines. In many places the way is to sink a perpendicular hole or shaft, the sides of which they strengthen from top to bottom with wood-work, to prevent the earth from falling in: the transverse pieces of wood used for this purpose, they call stemples; and by means of these the miners, in some places, descend without using any rope, catching hold of these with their hands and feet.

STENOGRAPHY, the art of writing short-hand. See **SHORT-HAND WRITING**.

STENONIAN DUCT, in anatomy. See **ANATOMY**, p. 307.

STEP of the mast and capstan, in a ship, is that piece of timber whereon the masts or capstans do stand at bottom.

STEPHEN, or **St. STEPHEN'S DAY**, a festival of the Christian church, observed on the 26th of December, in memory of the first martyr St. Stephen.

STERCULIA, in botany, a genus of the monœcia monodelphia class. The calix both of male and female consists of five segments; neither of them have any corolla: the male has 15 filaments; the germin rests upon a column; and there are five capsules containing many seeds. There are two species, both natives of India.

STEREOGRAPHIC PROJECTION, is the projection of the circles of the sphere on the plane of some one great circle, the eye being placed in the pole of that circle.

STEREOGRAPHY, the art of drawing the forms and figures of the solids upon a plane.

STEREOMETRY, that part of geometry which teaches how to measure solid bodies, *i. e.* to find the solidity or solid content of bodies, as globes, cylinders, cubes, vessels, ships, &c. See **GEOMETRY**.

STEREOTOMY, the art or act of cutting solids, or ma-

king sections thereof, as walls or other members in the profits of architecture.

STERILITY, the quality of a thing that is barren, in opposition to fertility.

Nature has annexed sterility to all monstrous productions, that all the creation might not degenerate. Hence the sterility of mules, &c.

STERLING, a term frequent in British commerce. A pound, shilling, or penny sterling, signifies as much as a pound, shilling, or penny of lawful money of Great Britain, as settled by authority. See **MONEY**.

STERN of a ship, usually denotes all the hindmost part of her, but properly it is only the outmost part abaft.

STERNBERG, a town of Germany, in the circle of Upper Saxony and marquisate of Brandenburg, situated twenty-three miles north-east of Frankfort upon the Oder.

STERNHOYDÆUS, in anatomy. See **ANATOMY**, p. 222.

STERNUM, in anatomy. See **ANATOMY**, p. 175.

STERNUTATORY, a medicine proper to produce sneezing. Sternutatives are of two kinds, gentle and violent. Of the first kind are betony, sage, marjoram, tobacco, and the whole fashionable tribe of snuffs. Of the latter kind are euphorbium, white hellebore, pellitory, &c.

STETIN, a city and port-town of Germany, in the circle of Upper Saxony, capital of the duchy of Pomerania, situated on the west shore of the river Oder: E. long. $14^{\circ} 50'$, N. lat. $53^{\circ} 30'$.

STEVENAGE, a market-town of Hertfordshire, situated thirty miles north of London, and ten north-west of Hertford.

STEW, a small kind of fish-pond, the peculiar office of which is to maintain fish, and keep them in readiness for the daily use of the family, &c.

STREWS, were also places anciently permitted in England to women of profligate continency, for the proffer of their bodies to all comers. These were under particular rules and laws of discipline, appointed by the lord of the manor.

STEWARD, an officer appointed in another's stead or place, and always taken for a principal officer within his jurisdiction. Of these there are various kinds. The greatest officer under the crown is the lord high steward of England, an office that was anciently the inheritance of the earls of Leicester, till forfeited by Simon de Mountfort to king Henry III. But the power of this officer is so very great, that it has not been judged safe to trust it any longer in the hands of a subject, excepting only *pro hac vice*, occasionally; as, to officiate at a coronation, at the arraignment of a nobleman for high-treason, or the like. During his office, the steward bears a white staff in his hand, and the trial &c. ended, he breaks the staff, and with it his commission expires. There is likewise a lord steward of the king's household, who is the chief officer of the king's court, has the care of the king's house, and authority over all the officers and servants of the household, except such as belong to the chapel, chamber, and stable.

STEWART, in Scots law. See **LAW**, Tit. iv. 5.

STEWARTIA, in botany, a genus of the monadelphia polyandria class. The calyx is simple; the stigma is quinquefid; the berry has five lobes, and one seed. There is but one species, a native of Virginia.

STEYNING, a borough-town of Suffolk: situated forty miles south of London, and thirteen miles west of Lewes. It sends two members to parliament.

STIBIUM, or **ANTIMONY**. See **CHEMISTRY**, p. 87, 139.

STICKLEBACK, in ichthyology. See **GASTEROSTEUS**.

STIGMA, in botany. See **BOTANY**, p. 637.

STIGMATA, the apertures in different parts of the bodies of insects, communicating with the tracheæ, or air-vessels, and serving for the office of respiration.

STIGMATA, in antiquity, certain marks impressed on the left shoulders of the soldiers when lifted.

STIGMATIZING, among the ancients, was inflicted upon slaves as a punishment, but more frequently as a mark to know them by, in which case it was done by applying a red-hot iron marked with certain letters to their foreheads, till a fair impression was made, and then pouring ink into their furrows, that the inscription might be the more conspicuous.

STILE. See **STYLE**.

STILES, in carpentry, denote the upright pieces which go from the bottom to the top of any waistcoat, or the like.

STILLATITIOUS OILS, such as are produced by distillation, in opposition to those got by infusion, expression, &c.

STILL-BOTTOMS, in the distillery, a name given by the traders to what remains in the still after the working the wash into low wines. These bottoms are procured in the greatest quantity from the malt-wash, and are of so much value to the distiller, in the fattening of hogs, &c. that he often finds them one of the most valuable articles of the business.

STIMULATING, a property in bodies, whereby they vellicate and cause vibrations and inflections of the fibres of the nerves, and a greater derivation of nervous fluid into the parts affected. Stimulants produce pain, heat, redness, &c.

STING, an apparatus in the body of certain insects, in form of a little spear, serving them as a weapon of offence. See **APIS**.

STINT, in zoology. See **ALAUDA**.

STIPA, in botany, a genus of the triandria digynia class. The calyx consists of two valves, containing one flower; the exterior valve of the corolla terminates in an awn; and it is jointed at the base. There are seven species, only one of them, *viz* the pennata, or feather grass, a native of Britain.

STIPEND, among the Romans, signified the same with tribute; and hence stipendiarii were the same with tributarii.

STIPEND, in Scots law. See **LAW**, Tit. v. 10, &c.

STIPULATION, in the civil law, the act of stipulating, that is, of treating and concluding terms and conditions to be inserted in a contract. Stipulations were anciently performed at Rome, with aundance of ceremonies; the first whereof was, that one party should intergate, and the other answer, to give his consent, and oblige himself. By the ancient Roman law, no body could stipulate but for himself: but as the tabelliones were public servants, they were allowed to stipulate for their masters; and the notaries, succeeding the tabelliones, have inherited the same privilege.

STIRIA DUCHY, in Germany, is part of the circle of Austria.

Austria, bounded by the duchy of Austria on the north, by Hungary on the east, and by Carinthia and Carniola on the south-west.

STIRLING, a town of Scotland, capital of the county of Stirling: situated on the river Forth, thirty miles north-west of Edinburgh; defended by a castle and other works.

STIRRUP, in the manege, a rest, or support for the horseman's foot, serving to keep him firm in his seat, and to enable him to mount.

STIRRUP of a ship, a piece of timber put upon a ship's keel, when some of her keel happens to be beaten off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ship's keel, and comes up on each side of the ship, where it is nailed strongly with spikes: and this they call a stirrup.

STIVES, the ancient Thebes, in the province of Achaia, now Livadia, in European Turkey.

STOCKHERN, a town of Germany, in the circle of Westphalia, and bishopric of Liège: situated on the river Maes, twelve miles north of Maeltricht.

STOCK, in gardening, &c. the stem or trunk of a tree.

STOCKBRIDGE, a borough-town of Hampshire, situated seven miles north-west of Winchester. It sends two members to parliament.

STOCK-BROKER. See **BROKER**, and the next article.

STOCK-JOBBER, the art or mystery of trafficking in the public ticks or funds. See **STOCKS**.

STOCKHOLM, the capital city of Sweden, situated on several small islands in the Mälar Lake: E. long. 18°, N. lat. 59° 30', three hundred miles north-east of Copenhagen, nine hundred north-east of London, and four hundred west of Peterburgh. It is neither walled nor fortified, being sufficiently secured by nature, with little rocks and islands, which surround it, though it has a spacious harbour sufficient for the largest fleets. That part of the town which is properly the city, stands upon a little island that is not more than a mile and a half in circumference, but the suburbs on the adjacent island are much larger. The inhabitants are computed about thirty thousand.

STOCKING, that part of the cloathing of the leg and foot which screens them from the cold, &c. Anciently, the only stockings in use were made of cloth, or of mixed stuffs sewed together: but since the invention of knitting and weaving stockings of silk, wool, cotton, thread, &c. the use of cloth stockings is quite out of doors.

STOCKPORT, a market-town of Cheshire, situated thirty-four miles north-east of Chester.

STO KTON, a port-town of Durham, situated near the mouth of the river Tees, sixteen miles south of Durham.

STOCKZOW, a town of Bohemia, in the duchy of Silesia, situated on the river Vistula, thirty-seven miles south-east of Trup paw.

STOCKS or PUBLIC FUNDS in England. As there are few subjects of conversation more general than the value of stocks, and hardly any thing so little understood, we shall here give account of them in as clear and concise a manner as possible; presenting our readers with the rationale

of the stocks, and a short history of the several companies*, describing the nature of their separate funds, the uses to which they are applied, and the various purposes they answer, both with respect to the government, the companies themselves, and the community in general.

In order to have a clear idea of the money-transactions of the several companies, it is necessary to know something of money in general, and the difference between that and the current specie. See the article **MONEY**.

Money is the standard of the value of all the necessities and accommodations of life; and paper money is the representative of that standard to such a degree, as to supply its place, and to answer all the purposes of gold and silver coin. Nothing is necessary to make this representative of money supply the place of specie, but the credit of that office or company who delivers it: which credit consists in its always being ready to turn it into specie whenever required. This is exactly the case of the bank of England: the notes of this company are of the same value as the current coin, as they may be turned into it whenever the possessor pleases. From hence, as notes are a kind of money, the counterfeiting them is punished with death as well as coining.

The method of depositing money in the bank, and exchanging it for notes (though they bear no interest) is attended with many conveniences; as they are not only safer than money in the hands of the owner himself, but as the notes are more portable and capable of a much more easy conveyance; since a bank note for a very large sum may be sent by the post, and, to prevent the designs of robbers, may, without damage, be cut in two, and sent at two several times. Or bills, called bank post-bills, may be had by application at the bank, which are particularly calculated to prevent losses by robberies, they being made payable to the order of the person who takes them out at a certain number of days after sight; which gives an opportunity to stop bills at the bank if they should be lost, and prevents their being so easily negotiated by strangers as common bank notes are: and whoever considers the hazard, the expence and trouble there would be in sending large sums of gold and silver to and from distant places, must also consider this as a very singular advantage. Beside which another benefit attends them; for if they are destroyed by time, or other accidents, the bank will, on oath being made of such accident, and security being given, pay the money to the person who was in possession of them.

Bank notes differ from all kinds of stock in these three particulars. 1. They are always of the same value. 2. They are paid off without being transferred; and, 3. They bear no interest: while stocks are a share in a company's funds, bought without any condition of having the principal returned. India bonds indeed (by some persons, tho' erroneously denominated stock) are to be excepted; they being made payable at six months notice, either on the side of the company or of the possessor.

By the word *stock* was originally meant a particular sum of money contributed to the establishing a fund to enable a company to carry on a certain trade, by means of which the person became a partner in that trade, and received a share of the profit made thereby, in proportion to the money made

page 1.

* Of these a general account only was given under the words **COMPANY**, and **BANK**, as it would be necessary to resume them in connection with the present article, the better to illustrate it.

employed. But this term has been extended farther, though improperly, to signify any sum of money which has been lent to the government, on condition of receiving a certain interest till the money is repaid, and which makes a part of the national debt. As the security both of the government and of the public companies is esteemed preferable to that of any private person, as the stocks are negotiable and may be sold at any time, and as the interest is always punctually paid when due; so they are thereby enabled to borrow money on a lower interest than what could be obtained from lending it to private persons, where there must be always some danger of losing both principal and interest.

But as every capital stock or fund of a company is raised for a particular purpose, and limited by parliament to a certain sum, it necessarily follows, that when that fund is completed, no stock can be bought of the company; though shares already purchased may be transferred from one person to another. This being the case, there is frequently a great disproportion between the original value of the shares, and what is given for them when transferred: for if there are more buyers than sellers, a person who is indifferent about selling will not part with his share without a considerable profit to himself; and, on the contrary, if many are disposed to sell, and few inclined to buy, the value of such shares will naturally fall, in proportion to the impatience of those who want to turn their stock into specie.

These observations may serve to give our readers some idea of the nature of that unjustifiable and dishonest practice called *stock jobbing*, the mystery of which consists in nothing more than this: The persons concerned in that practice, who are denominated stock-jobbers, make contracts to buy or sell, at a certain distant time, a certain quantity of some particular stock, against which time they endeavour, according as their contract is, either to raise or lower such stock, by raising rumours and spreading fictitious stories in order to induce people either to sell out in a hurry, and consequently cheap, if they are to deliver stock, or to become unwilling to sell, and consequently to make it dearer, if they are to receive stock.

The persons who make these contracts are not in general possessed of any real stock; and when the time comes that they are to receive or deliver the quantity they have contracted for, they only pay such a sum of money as makes the difference between the price the stock was at when they made the contract, and the price it happens to be at when the contract is fulfilled; and it is no uncommon thing for persons not worth 100 l. to make contracts for the buying or selling 100,000 l. stock. In the language of Exchange Alley, the buyer in this case is called the Bull, and the seller the Bear.

Beside these, there are another set of men, who, though of a higher rank, may properly enough come under the same denomination. These are your great moneyed men, who are dealers in stock, and contractors with the government whenever any new money is to be borrowed. These indeed are not fictitious, but real buyers and sellers of stock; but by raising false hopes, or creating groundless fears, by pretending to buy or sell large quantities of stock on a sudden, by using the fore-mentioned set of men as their instruments, and other like practices, are enabled to raise or lower the stocks one or two per cent. at pleasure.

However, the real value of one stock above another, on account of its being more profitable to the proprietors, or

any thing that will really, or only in imagination, affect the credit of a company, or endanger the government, by which that credit is secured, must naturally have a considerable effect on the stocks. Thus, with respect to the interest of the proprietors, a share in the stock of a trading company which produces 5 l. or 6 l. per cent. per annum, must be more valuable than an annuity with government security, that produces no more than 3 l. or 4 l. per cent. per annum; and consequently such stock must sell at a higher price than such an annuity. Though it must be observed, that a share in the stock of a trading company producing 5 l. or 6 l. per cent. per annum, will not fetch so much money at market as a government annuity producing the same sum; because the security of the company is not reckoned equal to that of the government, and the continuance of their paying so much per annum is more precarious, as their dividend is, or ought to be, always in proportion to the profits of their trade.

As the stocks of the East India, the bank, and South-Sea companies, are distinguished by different denominations, and are of a very different nature, we shall give a short history of each of them, together with an account of the different stocks each is possessed of; beginning with the East India company, as the first established.

Of the East India Company.

There is no trading company in Europe, the Dutch East India company excepted, which can be put in competition with this. Its was first established in the latter end of the reign of queen Elizabeth; and its privileges have been enlarged, or confirmed, by almost every monarch since. Its shares, or subscriptions, were originally only 50 l. sterling; and its capital only 369,891 l. 5 s. but the directors having a considerable dividend to make in 1676, it was agreed to join the profits to the capital, by which the shares were doubled, and consequently each became of 100 l. value, and the capital 739,782 l. 10 s.; to which capital, if 663,639 l. the profits of the company to the year 1685, be added, the whole stock will be found to be 1,703,402 l.

However, this company having sustained several losses by the Dutch, and the subjects of the great Mogul, was in a declining way at the Revolution, when the war with France reduced it so low, that it appearing scarcely possibly to be supported, a new one was erected. The merchants forming the new East India company received their charter in 1698, having, in consideration of the grant thereof, lent the government two millions at 8 per cent. per annum; and pushing their trade with vigour, they soon carried on twice the business that was ever done by the old company. But after the two companies had subsisted a few years in a separate state, means were contrived to unite them; which was effected in 1702, when a new charter was granted them under the title of the United Company of Merchants trading to the East Indies.

To the two millions advanced by the new company, the united company in the 6th of queen Anne lent the government 1,200,000 l. which made their whole loan amount to 3,200,000 l. A further sum was also lent by the company in 1730, on a renewal of their charter. the interest of which is reduced to 3 per cent. and called the India 3 per cent. annuities.

As to India stock, it is of a quite different nature; for as that is not money put out to interest, but the trading

stock

stock of the company; and the proprietors of the shares, instead of receiving a regular annuity, have a dividend of the profits arising from the company's trade; which, as it is more valuable, these shares generally sell at a price much above the original value.

As to the management of this united company, all persons without exception, natives and foreigners, men and women, are admitted members of it, and 500 l. in the stock of the company gives the owner a vote in the general court, and 2000 l. qualifies him to be chosen a director. The directors are 24 in number, including the chairman, and deputy chairman, who may be re-elected for four years successively. The chairman has a salary of 200 l. a year, and each of the directors 150 l. The meetings or courts of directors are to be held at least once a week; but are commonly oftener, being summoned as occasion requires.

Out of the body of directors are chosen several committees, who have the peculiar inspection of certain branches of the company's business; as the committee of correspondence, a committee of buying, a committee of treasury, a house committee, a committee of warehouses, a committee of shipping, a committee of accounts, a committee of law-suits, and a committee to prevent the growth of private trade, &c. who have under them a secretary, cashier, clerks, warehouse-keepers, &c.

Other officers of the company are governors and factors abroad; some of whom have guards of soldiers, and live in all the state of sovereign princes.

Of the Bank of England.

The company of the bank was incorporated by parliament, in the 5th and 6th years of king William and queen Mary, by the name of the Governor and Company of the Bank of England, in consideration of the loan of 1,200,000 l. granted to the government, for which the subscribers received almost 8 per cent. By this charter, the company are not to borrow under their common seal, unless by act of parliament; they are not to trade, or suffer any person in trust for them to trade in any goods or merchandise; but they may deal in bills of exchange, in buying or selling bullion, and foreign gold and silver coin, &c.

By an act of parliament passed in the 8th and 9th year of king William III. they were empowered to enlarge their capital stock to 2,201,711 l. 10s. It was then also enacted, that bank-stock should be a personal, and not a real estate; that no contract either in word or writing, for buying or selling bank-stock, should be good in law, unless registered in the books of the bank within seven days, and the stock transferred in 14 days; and that it should be felony, without benefit of clergy, to counterfeit the common seal of the bank, or any sealed bank-bill, or any bank-note, or to alter or erase such bills or notes.

By another act passed in the 7th of queen Anne, the company were empowered to augment their capital to 4,402,343 l. and they then advanced 400,000 l. more to the government, and in 1714 they advanced another loan of 1,500,000 l.

In the third year of the reign of king George I. the interest of their capital stock was reduced to 5 per cent. when the bank agreed to deliver up as many exchequer-bills as amounted to 2,000,000 l. and to accept an annuity of 100,000 l. and it was declared lawful for the bank to call

from their members, in proportion to their interests in the capital stock, such sums of money as in a general court should be found necessary. If any member should neglect to pay his share of the moneys so called for, at the time appointed by notice in the London Gazette, and fixed upon the Royal Exchange, it should be lawful for the bank not only to stop the dividend of such member, and to apply it toward payment of the money in question; but also to stop the transfers of the share of such defaulter, and to charge him with an interest of 5 l. per cent. per annum for the money so omitted to be paid; and if the principal and interest should be three months unpaid, the bank should then have power to sell so much of the stock belonging to the defaulter as would satisfy the same.

After this the bank reduced the interest of the 2,000,000 l. lent to the government from 5 to 4 per cent. and purchased several other annuities, which were afterward redeemed by the government, and the national debt due to the bank reduced to 1,600,000 l. But in 1742, the company engaged to supply the government with 1,600,000 l. at 3 per cent. which is now called the 3 per cent annuities, so that the government was now indebted to the company 3,200,000 l. the one half carrying 4, and the other 3 per cent.

In the year 1746, the company agreed that the sum of 986,800 l. due to them in the exchequer-bills unsatisfied, on the duties for licences to sell spirituous liquors by retail, should be cancelled, and in lieu thereof to accept of an annuity of 39,442 l. the interest of that sum at 4 per cent. The company also agreed to advance the further sum of 1,000,000 l. into the exchequer, upon the credit of the duties arising by the malt and land tax, at 4 per cent. for exchequer bills to be issued for that purpose; in consideration of which, the company were enabled to augment their capital with 986,800 l. the interest of which, as well as that of the other annuities, was reduced to 3 l. 10s per cent. till the 25th of December 1757, and from that time to carry only 3 per cent.

And in order to enable them to circulate the said exchequer bills, they established what is now called bank circulation: the nature of which not being well understood, we shall take the liberty to be a little more particular in its explanation than we have been with regard to the other stocks.

The company of the bank are obliged to keep cash sufficient to answer not only the common, but also any extraordinary demand that may be made upon them; and whatever money they have by them, over and above the sum supposed necessary for these purposes, they employ in what may be called the trade of the company; that is to say, in discounting bills of exchange, in buying of gold and silver, and in government securities, &c. But when the bank entered into the above mentioned contract, as they did not keep unemployed a larger sum of money than what they deemed necessary to answer their ordinary and extraordinary demands, they could not conveniently take out of their current cash so large a sum as a million, with which they were obliged to furnish the government. without either lessening that sum they employed in discounting, buying gold and silver, &c. (which would have been very disadvantageous to them,) or inventing some method that should answer all the purposes of keeping the million in cash. The method

which they chose, and which fully answers their end, was as follows.

They opened a subscription, which they renew annually, for a million of money; wherein the subscribers advance 10 per cent. and enter into a contract to pay the remainder, or any part thereof, whenever the bank shall call upon them, under the penalty of forfeiting the 10 per cent. so advanced; in consideration of which, the bank pays the subscribers 4 per cent. interest for the money paid in, and $\frac{1}{2}$ per cent. for the whole sum they agree to furnish; and in case a call should be made upon them for the whole, or any part thereof the bank farther agrees to pay them at the rate of 5 per cent. per annum for such sum till they repay it, which they are under an obligation to do at the end of the year. By this means the bank obtains all the purposes of keeping a million of money by them; and though the subscribers, if no call is made upon them (which is in general the case,) receive $6\frac{1}{2}$ per cent. for the money they advance, yet the company gains the sum of 23,500 l. per annum by the contract; as will appear by the following account.

| | |
|--|----------|
| The bank receives from the government | |
| for the advance of a million | £ 30,000 |
| The bank pays to the subscribers who advance | |
| 100,000 l. and engage to pay (when called | |
| for) 900,000 l. more | 6 500 |
| | <hr/> |
| The clear gain to the bank therefore is | 23 500 |
| | <hr/> |

This is the state of the case, provided the company should make no call on the subscribers; which they will be very unwilling to do, because it would not only lessen their profit, but affect the public credit in general.

Bank-stock may not improperly be called a trading stock, since with this they deal very largely in foreign gold and silver, in discounting bills of exchange, &c. Beside which, they are allowed by the government very considerable sums annually for the management of the annuities paid at their office. All which advantages render a share in their stock very valuable, though it is not equal in value to the East India stock. The company make dividends of the profits half-yearly, of which notice is publicly given. When those who have occasion for their money may readily receive it; but private persons, if they judge convenient, are permitted to continue their funds, and to have their interest added to the principal.

This company is under the direction of a governor, deputy-governor, and 24 directors, who are annually elected by the general court, in the same manner as in the East India company. Thirteen, or more, compose a court of directors for managing the affairs of the company.

The officers of this company are very numerous.

Of the South-Sea Company.

During the long war with France in the reign of queen Anne, the payment of the sailors of the royal navy being neglected, and they receiving tickets instead of money, were frequently obliged by their necessities to sell these tickets to avaricious men at a discount of 40 l. and sometimes 50 l. per cent. By this and other means the debts of the nation unprovided for by parliament, and which amounted to 9,471,321 l. fell into the hands of these usurers. On which, Mr Harley, at that time chancellor of the exchequer, and afterward earl of Oxford, proposed a scheme to

allow the proprietors of these debts and deficiencies 6 l. per cent. per annum, and to incorporate them in order to their carrying on a trade to the South Sea; and they were accordingly incorporated under the title of the Governor and Company of Merchants of Great Britain trading to the South-Seas and other parts of America, and for encouraging the Fishery, &c.

Though this company seemed formed for the sake of commerce, it is certain the ministry never thought seriously, during the course of the war, about making any settlements on the coast of South America, which was what flattered the expectations of the people; nor was it indeed ever carried into execution, or any trade ever undertaken by this company, except the Assiento, in pursuance of the treaty of Utrecht, for furnishing the Spaniards with negroes, of which this company was deprived by the late convention between the courts of Great Britain and Spain, soon after the treaty of Aix la Chapelle in 1748.

After this, some other sums were lent to the government in the reign of queen Anne at 6 per cent. In the third of George I. the interest of the whole was reduced to 5 per cent. and they advanced two millions more to the government at the same interest. By the statute of the 6th of George I. it was declared that this company might redeem all or any of the redeemable national debts, in consideration of which the company were empowered to augment their capital according to the sums they should discharge; and for enabling the company to raise such sums for purchasing annuities, exchanging for ready money new exchequer bills carrying on their trade, &c. the company might, by such means as they should think proper, raise such sums of money as in a general court of the company should be judged necessary. The company were also empowered to raise money on contracts, bills, bonds, or obligations under their common seal, on the credit of their capital stock. But if the sub-governor, deputy-governor, or other members of the company, should purchase lands or revenues of the crown upon account of the corporation, or lend money by loan or anticipation on any branch of the revenue, other than such part only on which a credit of loan was granted by parliament, such sub-governor, or other member of the company, should forfeit treble the value of the money so lent.

The first South-Sea scheme, transacted in the year 1720, was executed upon the last mentioned statute. The company had at first set out with good success, and the value of their stock for the first five years had risen faster than that of any other company; and his Majesty, after purchasing 10,000 l. stock, had condescended to be their governor. Things were in this situation, when, taking advantage of the above statute, the South-Sea bubble was projected. The pretended design of which was to raise a fund for carrying on a trade to the South Seas, and purchasing annuities, &c. paid to the other companies; and proposals were printed and distributed, shewing the advantages of the design, and inviting persons into it. The sum necessary for carrying it on, together with the profits that were to arise from it, were divided into a certain number of shares, or subscriptions, to be purchased by persons disposed to adventure therein. And the better to carry on the deception, the directors engaged to make very large dividends, and actually declared, that every 100 l. original stock would yield 50 l. per annum; which occasioned to great a rise of their stock, that a share of 100 l. was sold for upward of 1000 l. This was

in the month of July; but before the end of September it fell to 150 l. by which multitudes were ruined, and such a scene of distress occasioned as is scarcely to be conceived. But the consequences of this infamous scheme are too well known. We shall pass over all the other transactions of this company in the reign of King George I. as not material to our present purpose.

By a statute of the 6th of his late Majesty, it was enacted, that from and after the 24th of June 1733, the capital stock of this company which amounted to 14,651,103 l. 8 s. 1 d. and the shares of the respective proprietors, should be divided into four equal parts; three-fourths of which should be converted into a joint stock, attended with annuities, after the rate of 4 per cent. until redemption by parliament, and should be called The new South Sea annuities; and the other fourth part should remain in the company as a trading capital stock, attended with the residue of the annuities or funds payable at the exchequer to the company for their whole capital, till redemption: and attended with the same sums allowed for charge of management, and with all effects, profits of trade, debts, privileges and advantages belonging to the South Sea company. That the accountant of the company should twice every year, at Christmas and midsummer, or within one month after, state an account of the company's affairs, which should be laid before the next general court, in order to their declaring a dividend; and all dividends should be made out of the clear profits, and should not exceed what the company might reasonably divide without incurring any further debt; provided that the company should not at any time divide more than 4 per cent. per annum, until their debts were discharged; and that the South Sea company, and their trading stock, should, exclusively from the new joint annuities, be liable to all the debts and incumbrances of the company; and that the company should cause to be kept within the city of London, an office and books, in which all transfers of the new annuities should be entered and signed by the party making such transfer, or his attorney; and the person to whom such transfer should be made, or his attorney, should underwrite his acceptance, and no other method of transferring the annuities should be good in law.

The annuities of this company, as well as the other, are now reduced to 3 l. per cent.

This company is under the direction of a governor, sub-governor, deputy governor, and 24 directors; but no person is qualified to be governor, his Majesty excepted, unless such governor has, in his own name and right, 5000 l. in the trading stock; the sub-governor is to have 4000 l. the deputy 3000 l. and a director 2000 l. in the same stock. In every general court, every member having in his own name and right 500 l. in trading stock, has one vote: if 2000 l. two votes: if 3000 l. three votes; and if 5000 l. four votes.

The East India Company, the Bank of England, and the South Sea Company are the only incorporated bodies to which the government is indebted, except the Million Bank, whose capital is only one million, constituted to purchase the redemption of the long exchequer orders.

The interest of all the debts owing by the government is now reduced 3 per cent. excepting only the annuities for the years 1756 and 1758, the life annuities, and the exchequer orders: but the South Sea company still continues to divide four per cent. on their present capital stock, which they are enabled to do from the profits they make on the

sums allowed to them for management of the annuities paid at their office, and from the interest of annuities which are not claimed by the proprietors.

As the prices of the different stocks are continually fluctuating above and below par; so when a person who is not acquainted with transactions of that nature, reads in the papers the prices of stocks, where bank-stock is marked perhaps 127 l. India ditto 134 a 134½. South Sea ditto 97½, &c. he is to understand that a 100 l. of those respective stocks fell at such a time for those level sums.

In comparing the prices of the different stocks one with another, it must be remembered, that the interest due on them from the time of the last payment, is taken into the current price; and the seller never receives any separate consideration for it, except in the case of India bonds, where the interest due is calculated to the day of the sale, and paid by the purchaser over and above the premium agreed for. But as the interest on the different stocks is paid at different times, this, if not rightly understood, would lead a person not well acquainted with them into considerable mistakes in his computation of their value: some always having a quarter's interest due on them more than others, which makes an appearance of a considerable difference in the price, when in reality there is none at all. Thus, for instance, old South Sea annuities fell at present for £. 85½ or £. 85 10 s. while new South Sea annuities fetch only £. 84½, or £. 84 15 s. though each of them produce the same annual sum of £. 3 per cent. but the old annuities have a quarter's interest more due on them than the new annuities, which amounts to 1 s. the exact difference. There is, however, one or two causes that will always make one species of annuities sell somewhat lower than another, though of the same real value; one of which is, the annuities making but a small capital, and there not being for that reason so many people at all times ready to buy into it as into others where the quantity is larger; because it is apprehended, that whenever the government pays off the national debt, they will begin with that particular species of annuity the capital of which is the smallest.

A stock may likewise be affected by the court of chancery; for if that court should order the money which is under their direction to be laid out in any particular stock, that stock, by having more purchasers, will be raised to a higher price than any other of the like value.

By what has been said, the reader will perceive how much the credit and interest of the nation depends on the support of the public funds. While the annuities, and interest for money advanced, is there regularly paid, and the principal insured by both prince and people (a security not to be had in other nations' foreigners will lend us their property, and all Europe be interested in our welfare; the paper of the companies will be converted into money and merchandise, and Great Britain can never want cash to carry her schemes into execution).

In other nations, credit is founded on the word of the prince, if a monarchy; or that of the people, if a republic: but here, it is established on the interests of both prince and people: which is the strongest security: for however lovely and engaging honesty may be in other respects, interest in money-matters will always obtain confidence; because many people pay great regard to their interest, who have but little veneration for virtue.

STOCKS, among ship-carpenters, a frame of timber, and great posts, made ashore, to build pinnaces, ketches, boats, and such small craft, and sometimes small frigates. Hence we say, a ship is on the stocks, which she is a-building.

STOCKS, a wooden machine to put the legs of offenders in, for the securing of disorderly persons, and by way of punishment in divers cases, ordained by statute, &c.

STOEBE, in botany, a genus of the *syngenesia polygamia segregata* class. The receptacle is paleaceous; the pappus is feathered; and every floccule has a five-leaved calix. There is but one species, a native of *Æthiopia*.

STOICS, a sect of ancient philosophers, the followers of Zeno, thus called from the Greek *στοα*, which signifies a porch or portico, in regard Zeno used to teach under a portico or piazza.

To the praise of the Stoics in general, it must be confessed, that, less intent than other philosophers upon frivolous and often dangerous speculations, they devoted their studies to the clearing up of those great principles of morality which were the firmest supports of society; but the dryness and stiffness that prevailed in their writings, as well as in their manners, disgusted most of their readers, and abundantly lessened their utility. Zeno's chief followers, among the Greeks, were Lucippus, Cleanthes, Chrysippus, Diogenes Babylonius, Antipater, Panætius, Posidonius, and Epictetus; among the Romans, Cato, Varro, Cicero, Seneca, the emperor Antoninus, &c. The Stoics cultivated logic, physics, metaphysics, &c. but especially ethics. The principles of their dogmata, of the former kinds, are, that there are certain catalepsias or comprehensions, called innate ideas or principles, naturally found in the mind; that God is the seminal cause of the universe; and, with the Platonists, that the world is an animal, by reason of God's inhabiting and informing every part thereof; that nature is an artificial fire tending to generation; and that the world is at last to be destroyed by a conflagration. As for the morality of the Stoics, it was couched much in paradoxes; as, that a wise man is void of all passions, or perturbation of mind; that pain is no real evil, but that a wise man is happy in the midst of torture, is always the same, and is always joyful; that there is none else free; that none else ought to be esteemed king, magistrate, poet, or philosopher; that all wise men are great men; that they are the only friends or lovers; that nothing can happen to them beyond their expectations; that all virtues are insensibly connected together; that all good things are equal, and equally to be desired; that goodness admits of no increase or diminution. They own but one God, whom they however call by various names, as Fate, Jupiter, &c. by which they did not mean various things, but various powers and relations of the same thing. Providence they expressed under the name Fate, which Chrysippus defines to be a natural series or composition of things mutually following each other, by an immutable nexus or tie, fixed from all eternity. They held the immortality of the soul.

STOKEGOMER, a market-town of Somersetshire, situated twenty-two miles west of Wells.

STOKESLY, a market-town of Yorkshire, situated thirty miles north of York.

STOLBERG, a town of Germany, in the circle of Upper

Saxony, and territory of Thuringia, fifty-eight miles north-west of Leipzig.

STOLE, a sacerdotal ornament wore by the Romish parish-priests over their surplice, as a mark of superiority in their respective churches; and by other priests, over the alb, at celebrating of mass, in which case it goes across the stomach, and by deacons, over the left shoulder, scarf-wise; when the priest reads the gospel for any one, he lays the bottom of his stole on his head. The stole is a broad swath, or slip of stuff, hanging from the neck to the feet, with three crosses thereon.

Groom of the Stole, the eldest gentleman of his Majesty's bed chamber, whose office and honour it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber.

Order of the Stole, an order of knights instituted by the kings of Arragon. Another military order, at Venice, is called the order of the golden stole; thus called from a golden stole, which those knights wore over their shoulder, reaching to the knee, both before and behind, a palm and a half broad. None are raised to this order but patricians, or noble Venetians.

STOMACH, in anatomy. See *ANATOMY*, p. 258.

STOMACHIC, in pharmacy, medicines that strengthen the stomach, and promote digestion, &c.

Stomachic corroboratives are such as strengthen the tone of the stomach and intestines; among which are carminatives, as the roots of galangals, red ginseng, zedoary, pimpinella, calamus, aromaticus, and arum. Of barks and rinds, those of canella alba, saffras, citrons, Seville and China oranges, &c. Of spices, pepper, ginger, cloves, cinnamon, cardamums, and mace.

STONES, in natural history, are defined to be essentially compound fossils, not inflammable, nor soluble in water or oil, nor at all ductile; found in continued strata, or beds, of great extent; formed either of a congeries of small particles, in some degree resembling sand, and lodged in a smoother cementitious matter; or else of this cementitious matter, and the grit or sand-like particles, running together into one smooth mass; or, finally, of granules cohering by contact, without any cementitious matter among them; or composed of crystal or spar, usually debased by earth, and often mixed with talc and other extraneous particles.

Of this class of fossils there are three orders; and under these, eight genera.

The first order comprehends all the coarse, harsh, and rough stones, of a lax texture, and composed of a visible grit, resembling sand in form, and usually immersed in a cementitious matter, and of little natural brightness; scarce capable of any polish, and naturally mouldering away in form of powder from the tools of the workmen. The genera of this order are two, *viz.* the ammochista and pladioria; the former of which constitute our grey and rough lates; and the latter comprehends most of the stones used in building, particularly Portland stone.

The second order consists of stones moderately fine, of a more compact and even texture, scarce distinguishable construction, and affording no sand-like particles to the view; of some natural brightness, capable of a tolerable polish, and flying off from the tools of the workmen in form of small chips. Under this order are comprehended the *symplexia* and *stegania*.

The

The third order consists of stones of a very fine substance and elegant structure, naturally of a great brightness, and capable of an elegant polish; composed of granules of various shapes and sizes, but usually flutish, sometimes more, sometimes less distinct; and, in some species, running together into uniform masses, but never lodged in any cementitious substance. Of this order are the marbles, alabasters, porphyries, and granites.

STONE in the bladder. See **MEDICINE**, and **SURGERY**. **STONE** also denotes a certain quantity or weight of some commodities.

A stone of beef, at London, is the quantity of eight pounds; in Hertfordshire, twelve pounds; in Scotland, sixteen pounds.

STONE CHATTER, in ornithology. See **MOTACILLA**.

STONEHENGE, in antiquity. a famed pile or monument of huge stones on Salisbury plain, six miles distant from that city.

It consists of the remains of four ranks of rough stones, ranged one within another, some of them, especially in the outermost and third rank, twenty feet high, and seven broad; sustaining others laid across their heads, and fastened by mortises: so that the whole must have anciently hung together.

Antiquaries are now pretty well agreed that it was a British temple; and Dr Langwith thinks it might easily be made probable, at least, that it was dedicated to the sun and moon. Inigo Jones has given a fine scheme of the work, and strives hard to persuade the world, that it was Roman: but Dr Langwith, who took his measures on the spot, assures us he could by no means reconcile them with that scheme.

STONEY STRATFORD, a market-town of Buckinghamshire. fourteen miles north of Ailebury.

STOOL, in medicine, an evacuation or discharge of the fæces, &c. by the anus.

STOPPER, in a ship, a piece of cable-laid rope, having a wale-knot at one end, with a laniard fastened to it; and the other end is spliced round a thimble in the ring-bolts upon deck, and at the bits: its use is to stop the cable, that it may not run out too fast; in order to which, they make turns with the laniard about the cable, and the wale-knot stops it, so that it cannot slip away faster than is necessary.

STORAX, or **STYRAX**, in natural history, a dry and solid resin, of a reddish colour, and a peculiarly fragrant smell; of which there are two kinds, the styrax calamita, or styrax in tears, and the styrax vulgaris; whereof the former is by far the purer and finer kind, imported in small loose granules, or else in large masses composed of such granules: it is anciently used to be packed up in reeds, for the more secure carriage; whence the name. The common storax is likewise a fine and pure resin, though less so than the former; and is brought to us in large lumps, not formed of granules, but of one uniform consistance.

These are the two genuine kinds of storax; but neither of them is that met with in our shops, which is a kind of saw-dust connected into lumps, by just so much of the storax resin as will make the other matters hang together. This is what our apothecaries use, under the name of storax; but it is advisable to strain carefully the pure resin from the filth, and use no part of the latter.

The two genuine kinds of storax, which ought always

to be used where they can be had, differ only in this; that the granulated storax flows naturally from the styrax tree, and the common kind is obtained from the same tree by incision.

Storax is brought to us from Syria, and the East-Indies; and ought to be chosen pure, very fragrant, and of an acid taste. It is much recommended as a detergent and balsamic, in disorders of the breast: it is also esteemed a cordial, and is recommended in vertiges and other disorders of the head and nerves.

Liquid STORAX, in pharmacy, is a drug very different from the resin above described; being a resinous juice, of the consistance of venice-turpentine, or thicker: it is, when clean, pellucid, of a brownish colour, with a cast sometimes of reddish, and sometimes of greyish in it. Its smell is somewhat like that of common storax, only much stronger, and even disagreeable: its taste is acrid, aromatic, and somewhat bitterish; and it is oily, or unctuous. It should be chosen thin, pellucid, of a clean brown colour, and of a very strong smell.

STORGE, a greek term, frequently used for the parental instinct, or natural affection, which almost all animals bear their young; whereby they are most powerfully moved to defend them from dangers, and procure for them suitable nourishment.

STORK, in ornithology. See **ARDEA**.

STORM BIRD. See **PROCELLARIA**.

STORMAR, the fourth division of Holstein, whereof Ham-burgh is the chief town.

STORTFORD, a market-town of Hertfordshire, thirty miles north of London.

STOVES, in gardening, are buildings erected for the preservation of tender exotic plants, which, without that assistance, will not bear the cold of our winter, because they require an artificial warmth.

Stoves are of two kinds, distinguished by the names of the dry and the bark-stoves.

The dry stove has the flues, in which the smoke is carried, either laid under the pavement of the floor, or erected in the back part of the house over each other, and returned six or eight times all along the stove. In these stoves the plants are placed on scaffolds, and benches of boards, raised above one another; and the plants principally preferred in these are the aloes, ceruses, euphorbiums, tithymals, and other succulent plants, which are impatient of moisture in winter, and therefore are not to be kept among trees, or herbaceous plants, which perspire freely.

The bark-stoves are made with a large pit, nearly of the length of the house, which is three feet deep, and six or seven feet wide. This pit is to be filled with fresh tanner's bark to make a hot-bed, and in this the pots containing the tender plants are to be plunged.

STOURBRIDGE, a market-town, nineteen miles north of Worcester.

STOUTH-RIEF, in Scots law. See **LAW**, Tit. xxxiii. 30.

STOW, a market-town, twenty miles east of Gloucester.

STOWAGE, in the sea language, the placing goods orderly in the hold of a ship, viz. the heaviest next the ballast, &c.

STOWEY, a market-town of Somersetshire, eighteen miles west of Wells.

STOW MARKET, a town of Suffolk, ten miles east of Bury.

STRABISMUS, *SQUINTING*, a distortion of the eyes, whereby their pupils are turned from, instead of being directed to cards, objects at which they look : sometimes only one eye. but more frequently both are thus affected. See *MEDICINE*, p. 155.

STRAIN, in surgery, a violent extension of the sinews, or tendons, of some muscle.

STRAIT, is a narrow passage out of one sea into another, as those of Gibraltar and Magellan.

STRAKES, in the sea-language, signify the uniform ranges of planks on the bottom, decks, and sides of ships ; and the garboard-strake is that next the keel.

STRALSUND, a strong city and port-town of Germany, in the circle of Upper Saxony and duchy of Pomerania, subject to Sweden: E. long $13^{\circ} 22'$, and N. lat. $54^{\circ} 23'$.

STRAND, signifies any shore of the sea, or bank of a great river : hence an immunity from paying customs on goods or vessels, was anciently expressed by strand and stream.

STRANDED, among seamen, is said of a ship that is driven ashore by a tempest, or runs on ground through ill steering, and so perishes.

STRANGFORD, a town of Ireland, that gives name to a loch and bay in the county of Down and province of Ulster, situated nine miles east of Down.

STRANGURY, in medicine a suppression of urine. See *MEDICINE*, p. 160.

STRANRAER, a parliament-town of Scotland, situated in the shire of Galloway, on a bay of the frith of Clyde.

STRAPS of a saddle, are strong leather-thongs, nailed to the bows of a saddle, in order to make the girths, &c. fast.

STRAPADO, a kind of military punishment, wherein the criminal is hoisted up by a rope, and let down, so that, by the weight of his body in the fall, his arms are dislocated.

STRASBURG, a free imperial city of Germany, capital of the landgraviate of Alsace, situated near the western bank of the Rhine, in E. long. $7^{\circ} 35'$, and N. lat. $48^{\circ} 38'$.

STRATA, in natural history, the several beds or layers of different matters, whereof the body of the earth is composed.

The strata include all the layers of earths, minerals, metals, stones, &c. lying under the upper tegument, or stratum, the turf or mould.

The time when these several strata were laid, was doubtless at the creation ; unless, with some great naturalists, as Sieno. Dr. Woodward, &c. we suppose the globe of the earth to have been dissolved by the deluge.

STRATAGEM, in the art of war, any device for the deceiving and surprising an enemy.

STRATEGUS, in Grecian antiquity, an annual officer among the Athenians, whereof there were two chosen, to command the troops of the state.

STRATFORD, a populous market-town of Warwickshire, situated on the river Avon, six miles south of Warwick ; remarkable for being the birth-place of the inimitable Shakespeare, and lately for the Jubilee held there in honour of his memory, September 1769.

STRATHNAVER, a subdivision or district of the county of Sutherland, in Scotland, having the Caledonian ocean on the north and west.

STRATIFICATION, in chemistry, the ranging any thing

to be calcined in several layers or strata one above another.

STRATIOTES, in botany, a genus of the polyandria hexagynia class. The spathe consists of two leaves, and the perianthium of three segments ; the corolla has three petals, and the berry has six cells. There are two species, one of them, *viz.* the aloides, water-aloce, or fresh-water soldier, a native of Britain.

STRATTON, a market-town of Cornwall, situated a little south of the Britol channel, fourteen miles north-west of Launceston.

STRAWBERRY, in botany. See *FRAGARIA*.

STRAWBERRY-TREE, in botany. See *ARBUTUS*.

STRENGTH, in physiology, the same with force or power.

STRENGTHENERS, in pharmacy, medicines that add to the bulk and firmness of the solids : and such are all astringent, agglutinant, and astringent medicines.

STRLE, in the ancient architecture, the same with the flutings of columns. See *FLUTES*.

STRIATED LEAF, among botanists, one that has a number or longitudinal furrows on its surface.

STRIGONENSIS TERRA, *earth of Strigonium*, in the materia medica, a red earth, of the hole kind, found about the gold-mines at Strigonium in Hungary, and used in some places as an astringent and sudorific.

It is but of a coarse and impure texture, and lighter than most of the boles in colour ; it is of a strong, but dull red, and is of a tolerably smooth surface ; it is apt to crumble to pieces between the fingers, and stains the skin in handling ; it melts freely in the mouth, and has a remarkable smoothness, but very little astringency in its taste, and leaves a sensible grittiness between the teeth ; it is sometimes veined and spotted with small molecules of an earth, like the whitish variegations of the red French bole.

STRIKE, a measure of capacity, containing four bushels.

STRIKE, among seamen, is a word variously used : when a ship, in a fight, or on meeting with a ship of war, lets down or lowers her top-masts, at least half-mast high, they say she strikes, meaning she yields, or submits, or pays respect to the ship of war. Also, when a ship touches ground, in shoal-water, they say she strikes. And when a top-mast is to be taken down, the word of command is, Strike the top-mast, &c.

STRIX, in ornithology, a genus belonging to the order of accipitres. The bill is hooked, but has no cere or wax ; the nostrils are covered with setaceous feathers ; the head is very large, as are also the ears and eyes ; and the tongue is biid. There are twelve species, comprehending all the owl-kind. They are night-birds, and feed upon mice, bats, &c.

STROBILUS, among botanists. See *BOTANY*, p. 637.

STROMATEUS, in ichthyology. a genus belonging to the order of apodes. The head is compressed, the teeth are in the jaws and palate ; the body is oval, and slimy ; and the tail is forked. There are two species.

STROMBOLI, one of the Lipari islands, fifty miles north of Messina.

STRONGOLI, a town of the Hither Calabria, in the kingdom of Naples, situated on the gulph of Tarante.

STROPHE, in ancient poetry, a certain number of verses, including a perfect sense, and making the first part of an ode.

STROUD, a market-town, nine miles south of Gloucester.

STRUMÆ,

STRUMÆ, scrophulous tumours arising on the neck and throat, constituting what is commonly called the king's evil. See *MEDICINE*, p. 137, &c.

STRUTHIO, the ostrich in ornithology, a genus belonging to the order of grallæ. The bill is somewhat conical; the nostrils are oval; the wings are short, and not fit for flying; and the feet are of the running kind. There are three species. The camelus, or common ostrich, is a native of Syria, Arabia, Lybia, and Africa. This is the largest of all birds; it runs swifter than any animal; it lays about 50 eggs in the sand, and sits upon them only during the night the heat of the sun being sufficient during the day.

STRYCHNOS, in botany, a genus of the pentandria monogynia class. The corolla consists of five segments; and the berry has but one cell. There are two species, both natives of Britain.

STUCCO, in building, a composition of white marble, pulverized and mixed with plaster of lime; and the whole being sifted and wrought up with water, is to be used like common plaster: this is what Pliny means by marmortum opus, and albarium opus.

STUFF, in commerce, a general name for all kinds of fabrics of gold, silver, silk, wool, hair, cotton, or thread, manufactured on the loom; of which number are velvets, brocades, mohairs, satins, taffeties, cloths, serges, &c.

STUM, in the wine-trade, denotes the unfermented juice of the grape, after it has been several times racked off and separated from its sediment. The casks are, for this purpose, well matched, or fumigated with brimstone every time, to prevent the liquor from fermenting, as it would otherwise readily do, and become wine.

STUPOR, a numbness in any part of the body, whether occasioned by ligatures obstructing the blood's motion, by the palsy, or tie-like.

STUPHA, or **STUPE**, in medicine, is a piece of cloth dipped in some proper liquor, and applied to an affected part, by way of fomentation or epithem.

STURGEON. See *ACCIPENSER*.

STURMINSTER, a market town, eighteen miles north of Dorchester.

STURNUS, the STARLING, in ornithology, a genus belonging to the order of passeræ. The beak is tubulated, depressed, and somewhat blunt; the superior mandible is entire, and somewhat open at the edges; the nostrils are margined above; and the tongue is sharp and emarginated. There are five species, distinguished by their colour.

STYLE, a word of various significations, originally deduced from *stylos*, a kind of bodkin, wherewith the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory-leaves, and paper prepared for that purpose, &c.

STYLE, in dialling, denotes the gnomon or cock of a dial, raised on the plane thereof to project a shadow. See *DIALLING*.

STYLE, in botany. See *BOTANY* p. 637.

STYLE, in matters of language, a particular manner of expressing one's thoughts agreeably to the rules of syntax; or, as F. Buffon more accurately defines it, the manner wherein the words, continued according to the laws of syntax, are arranged among themselves, suitably to the genius of the language. See *COMPOSITION*.

STYLE, in jurisprudence, the particular form or manner of proceeding in each court of jurisdiction, agreeable to the rules and orders established therein: thus we lay the style of the court of Rome, of Chancery, of Parliament, of the Privy council, &c.

Old-STYLE, the Julian manner of computing time, as the *New STYLE* is the Gregorian method of computation. See *ASTRONOMY*, p. 490.

STYLET, a small dangerous kind of poinard, which may be concealed in the hand, chiefly used in treacherous assassinations. The blade is usually triangular, and so slender that the wound it makes is almost imperceptible.

STYLITES, an appellation given to a kind of solitaries, who spend their lives seated on the tops of columns, to be, as they imagine, the better disposed for meditation, &c. Of these we find several mentioned in ancient writers, and even as low as the eleventh century. The founder of the order was St. Simon Stylites, a famous anchorite in the fifth century, who took up his abode on a column six cubits high; then on a second, of twelve cubits a third, of twenty-two; and, at last, on another of thirty-six. The extremity of these columns were only three feet in diameter, with a kind of rail or ledge about it that reached almost to the girdle, somewhat resembling a pulpit. There was no lying down in it. The fakirs, or devout people of the east, imitate this extraordinary kind of life even to this day.

STYLOGLOSSUS, in anatomy. See *ANATOMY*, p. 304.

STYLOHYOIDÆUS, in anatomy. See *ANATOMY*, p. 304.

STYLOIDES, in anatomy. See *ANATOMY*, p. 155.

STYLOPHARYNGÆUS, in anatomy. See *ANATOMY*, p. 305.

STYPHIC, in pharmacy, medicines which by their astringent qualities stop hæmorrhages.

STYRAX, in botany, a genus of the dodecandria monogynia class. The calix consists of five teeth, and the corolla of one funnel-shaped petal; and the drupa has one cell, containing two seeds. There is but one species, a native of Syria. See *STORAX*.

SUBALTERN, a subordinate officer, or one who discharges his post under the command, and subject to the direction of another: such are lieutenants, sub-lieutenants, cornets and ensigns, who serve under the captain.

SUBBUTEO, in ornithology. See *FALCO*.

SUBCLAVIAN, in anatomy, is applied to any thing under the arm-pit or shoulder, whether artery, nerve, vein, or muscle.

SUBCOSTAL MUSCLES. See *ANATOMY*, p. 215.

SUBER, in botany. See *QUERCUS*.

SUBJECT, a person under the rule and dominion of a sovereign prince or state.

SUBJECT, is also used for the matter of an art or science, or that which it considers, or whereon it is employed: thus the human body is the subject of medicine.

SUBJUNCTIVE, in grammar. See *GRAMMAR*.

SUBLIMATE, a chemical preparation, the basis whereof is mercury or quick-silver. See *CHEMISTRY*, p. 138.

SUBLIMATION, the condensing and collecting in a solid form, by means of vessels aptly constructed, the fumes of bodies raised from them by the application of a proper heat. See *CHEMISTRY*, p. 138.

SUBLINGUAL GLANDS. See *ANATOMY*, p. 307.

SUBMISSION, in Scots law. See **LAW**, Tit. xxxii. 15.

SUBORDINATION, a relative term, expressing the degree of inferiority between one thing and another.

SUBORNATION OF PERJURY, in Scots law. See **LAW**, Tit. xxxiii. 35.

SUBPOENA, in law, a writ whereby all common persons, or those under the degree of peerage, may be called into chancery, in any case where the law cannot afford a remedy.

SUBREPTION, the act of obtaining a favour from a superior, by surprise or a false representation.

SUBREPTITIOUS, a term applied to a letter, licence, patent, or other act, fraudulently obtained of a superior, by concealing some truth, which, had it been known, would have prevented the concession or grant.

SUBROGATION, in the civil law, the act of substituting a person in the place, and entitling him to the rights of another.

SUBSCAPULARIS, in anatomy. See **ANATOMY**, p. 196.

SUBSCRIPTION, in general, signifies the signature put at the bottom of a letter, writing, or instrument.

SUBSEQUENT, something that comes after another, particularly with regard to the order of time.

SUBSIDY, in law, signifies an aid or tax granted to the king, by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods: but this word, in some of our statutes, is confounded with that of customs.

SUBSISTENCE, in the military art, is the money paid to the soldiers weekly, not amounting to their full pay; because their cloaths, accoutrements, tents, bread, &c. are to be paid.

SUBSTANCE, something that we conceive to subsist of itself, independently of any created being, or any particular mode or accident. See **METAPHYSICS**.

SUBSTANTIAL, in the schools, something belonging to the nature of substance.

SUBSTANTIVE, in grammar. See **GRAMMAR**.

SUBSTITUTE, a person appointed to officiate for another, in case of absence or other legal impediment.

SUBSTITUTION, in the civil-law, a disposition of a testament, whereby the testator substitutes one heir for another, who has only the usufruct, and not the property of the thing left him.

SUBTRACTION, in arithmetick. See **ARITHMETICK**, p. 370.

SUBTRACTION, in algebra. See **ALGEBRA**, p. 81.

SUBTENSE, in geometry, the same with the chord of an arch. See **CHORD**.

SUBTERRANEAN, whatever is under-ground: thus, naturalists speak of subterraneous fires, damps, &c.

SUBTILE, in physics, an appellation given to whatever is extremely small, fine, and delicate; such as the animal spirits, the effluvia of odorous bodies, &c. are supposed to be.

SUBULARIA, in botany, a genus of the tetradynamia siliculosa class. The pod is entire, oval, with oval concave valves; and the stylus is shorter than the pod. There is but one species, *viz.* the aquatica, or awl-wort, a native of Britain.

SUBULATED, something in the shape of an awl.

SUCCEDANEUM, in pharmacy, denotes a drug substi-

tuted in the place of another, in medical composition.

SUCCESSION, in philosophy, an idea which we get by reflecting on that train of ideas constantly following one another in our minds when awake.

SUCCESSION, in Scots law. See **LAW**, Tit. xxvii. 16 &c. xxviii. 1, &c.

SUCCESSOR, in law, one that succeeds, or comes in the place of another.

SUCCINUM, in natural history. See **AMBER**.

SUCCISA, in botany. See **SCABIOSA**.

SUCCORY, in botany. See **CICORIUM**.

SUCCUBUS, a term used by some imaginary writers, for a demon who assumes the shape of a woman, and as such lies with a man; in which sense, it stands opposed to incubus, which was a demon in form of a man, that they supposed to lie with a woman.

But the truth is, the succubus is only a species of the incubus, or night-mare. See **MEDICINE**, p. 157.

SUCCULA, in mechanics, a bare axis, or cylinder, with flaves to move it round; but without any tympanum or peritrochium.

SUCCULENT PLANTS, those whose leaves are thick, and abound with juice.

SUCHUEN, a province of China, bounded by that of Xensu on the north, by Honam and Huquam on the east, by Quecheu and Yunam on the south, and by the mountains of India on the west: its chief town is Chingtu.

SUCKERS, in gardening, the same with off-sets. See **OFF SETS**.

SUCTION, the act of sucking or drawing up a fluid, as air, water, milk, or the like, by means of the mouth and lungs. See **PNEUMATICS**, and **HYDROSTATICS**.

SUDATORY, a name given by the ancient Romans to their hot or sweating-rooms; sometimes also called laconica.

SUDBURY, a borough-town of Suffolk, thirteen miles south of Bury. It sends two members to parliament.

SUDORIFIC, an appellation given to any medicine that causes or promotes sweat.

SUEZ, a port-town of Egypt, situated at the bottom of the Red-sea, seventy miles east of Cairo: it is from this town that the isthmus of Suez, which joins Africa to Asia, takes its name.

SUFFOCATION, in medicine, the privation of respiration, or breathing; which is sometimes occasioned by a congestion of blood in the lungs, so as to prevent the ingress of the air.

SUFFOLK, a county of England, bounded by Norfolk on the north, by the German-sea on the east, by Essex, from which it is separated by the river Maningtree, on the south, and by Cambridgeshire on the west; being sixty two miles long, and twenty-eight broad.

SUFFRAGAN, an appellation given to simple bishops, with respect to archbishops, on whom they depend, and to whom appeals lie from the bishops courts.

SUFFRAGE, denotes a vote given in an assembly, where something is deliberated on, or where a person is elected to an office or benefice.

SUFFRUTEX, among botanists, denotes an under-shrub, or the lowest kind of woody plants, as lavender, rue, &c.

SUGAR, in natural history, is properly the essential salt of the sugar-cane, as tartar is of the grape. See **CHEMISTRY**, p. 161. and **SACCHARUM**.

This plant rises to eight, nine, or more feet high; the stalk,

stalk, or cane, being round, jointed, and two or three inches in diameter at the bottom : the joints are three or four inches asunder, and in a rich soil more : the leaves are long and narrow, and of a yellowish green colour ; as is also the stalk itself, the top of which is ornamented with a panicle, or cluster of arundinaceous flowers, two or three feet in length.

They propagate the sugar-cane, by planting cuttings of it in the ground in furrows, dug parallel for that purpose : the cuttings are laid level and even, and are covered up with earth ; they soon shoot out new plants from their knots or joints : the ground is to be kept clear, at times, from weeds ; and the canes grow so quick, that in eight, ten, or twelve months, they are fit to cut for making of sugar from them. The manner of doing it is thus : They cut off the reeds at one of the joints near the roots ; they are then cleared of the leaves, and tied up in bundles, and sent to the mills, which are worked either by water or horses.

The sugar-mill is composed of three rollers of an equal size, and all armed with iron plates, where the canes are to pass between them ; only the middle roller is much higher than the rest, to give the larger sweep to the two poles to which the horses are yoked. This great roller in the middle is furnished with a cog full of teeth, which catch the notches in the two side-rollers, and force them about to bruise the canes, which pass quite round the great roller, and come out dry and squeezed from all their juice ; which runs into a vessel or back under the mill, and is thence conveyed through a narrow spout into the first boiler.

After the juice is let out of the first vessel, it is received into another ; in which it is boiled more briskly, and skimmed from time to time with a large kind of spoon, pierced with holes to let the liquor through, while it retains the scum and foulness separated from it in boiling : towards the end of this boiling, they throw into it a strong lixivium of wood-ashes, with some quick-lime among it : this greatly promotes the separation of the foulness that yet remains amongst it ; and, after it has boiled some time with this addition, they strain it off. The feces left in the cloths make a kind of wine, when fermented properly with water. The strained liquor, which is now tolerably clean, is let into a third boiler, in which it is boiled down to the consistence of sugar over a very brisk fire, the people who attend it continually stirring and skimming it.

Great caution is to be used that the boiling matter does not rise over the sides of the vessel, which would be of very dangerous consequence : they prevent this by taking up quantities of the boiling matter with a ladle, lifting it up high, and letting it run in again, and by now and then adding a small piece of butter, or fat of some kind, which takes down the bubbling almost instantaneously. They are very careful that no lemon-juice, or any other acid of that kind, comes near the vessels, a very small admixture of that being sufficient to keep the matter from granulating. When the liquor is boiled enough, which is known by its concreting on throwing a spoonful of it up into the air, it is then let out into a fourth vessel, under which there is a very gentle fire, only kept up that it may have leisure to granulate ; when it has begun to granulate, it is let out of this last boiler into a kind of

conic earthen vessels, open at both ends ; the widest aperture is placed upwards, and the smaller end downwards, its aperture being stopped with a wooden plug. It is left in these vessels twenty-four hours to concrete : after this they are removed into sugar-houses, and are there arranged in regular order, with a vessel of earthen-ware under each ; the plug is then taken out of the bottom aperture of each, and they are left in this condition for about forty days, that all the thick liquor, or melassies, may run from them : after they have stood thus long to drain of themselves, a quantity of clay is diluted, with water, into a thin paste ; and this is poured on the top of every parcel of sugar in the vessels, so as to cover it two or three inches deep. This water, by degrees, all leaves the clay, and penetrating into the mass of sugar, runs through it, and carries off yet more of this foul thick liquor with it, into the vessels placed underneath to receive it.

When the clay is quite dry, it is taken off, and the first preparation of the sugar is now finished ; they shake it out of the vessels ; and, cutting it into lumps, which are of a dirty, brownish, or greyish colour, they put it up in hogheads, and other casks, under the name of grey or brown sugar. The sugar, in this state, ought to be dry, not unctuous, and to have no taste of burning. The liquor which has run from the sugar in standing, is boiled to a consistence, and sold under the name of melassies, or treacle ; this affords, by fermentation, a very clean and good spirit.

This coarse sugar is afterwards refined to various degrees of purity by new solutions, and is sold at different prices, and under different names, according to the degree of purity it is brought to. Our sugar refiners first dissolve it in water, then clarify the solution by boiling with whites of eggs and despumation ; and after due evaporation pour it into moulds ; where the fluid part being drained off, and the sugar concreted, its surface is covered with moist clay, as before. The sugar thus once refined, by repetition of the process becomes the double-refined sugar of the shops. The candy-sugar, or that in crystals, is prepared by boiling down solutions of sugar to a certain pitch, and then removing them into a hot room, with sticks placed across the vessel for the sugar to shoot upon : and these crystals prove of a white or brown colour, according as the sugar used in the process was pure or impure.

SUGILLATION, in medicine, an extravasation of blood in the coats of the eye, which at first appears of a reddish colour, and afterwards livid or black. If the disorder is great, bleeding and purging are proper, as are discutients.

SUIT, in law, is used in different senses ; as, 1. For an action, whether personal or real. 2. Suit of court, or suit-service, which is an attendance the tenant owes to his lord's court. 3. Suit-covenant, where a person has covenanted to do service in the court of the lord. 4. Suit-custom, which is where one and his ancestors have owed suit time out of mind. 5. It is used for a petition to the king, or any person of dignity ; where a lord distrains his tenant for suit, and none is due ; in this case, the party may have an attachment against him to appear in the king's court. 6. Suit of the king's peace, is an action brought against a person for breach of the king's peace ; as in the case of treasons, felonies, or trespasses.

SULPHUR. See CHEMISTRY, p. 72, 118.

SULTAN, a title of honour, given to the emperor of the Turks. The wife of a sultan is called sultana, and the favourite one *hâfeki-sultana*, *i. e.* the private sultana.

SUM, signifies the quantity that arises from the addition of two or more magnitudes, numbers, or quantities together. See ARITHMETIC.

SUMACH, in botany. See RHUS.

SUMATRA, an island in the East-indian ocean, situated between 93° and 104° E. long. and between 5° 30' N. lat. and 5° 30' S. lat. extending from north-west to south-east, nine hundred miles long, and from one hundred to one hundred and fifty broad.

SUMMARY, in matters of literature. See ABRIDGMENT.

SUMMER, one of the seasons of the year, commencing in these northern regions on the day the sun enters Cancer, and ending when he quits Virgo. See ASTRONOMY, p. 554.

SUMMIT, the top or vertex of any body, or figure; as of a triangle, cone, pyramid, &c.

SUMMONS, in Scots law. See LAW, Tit. xxx. 28.

SUN, in astronomy. See ASTRONOMY, p. 435.

SUN-FLOWER, in botany. See HÉLIANTHUS.

SUNDA-ISLANDS, those situated near the straits of Sunda, in the Indian ocean; the chief of which are Borneo, Java, Sumatra, &c. See BORNEO, &c.

SUNDAY, or the LORD'S-DAY, a solemn festival observed by Christians on the first day of every week, in memory of our Saviour's resurrection.

This is the principal and most noted of the Christian festivals, and was observed with great veneration in the ancient church, from the time of the apostles, who themselves are often said to have met on that day for divine service. It is likewise called the Sabbath-day as being substituted in the room of the Jewish sabbath. See SABBATH.

The ancients retained the name Sunday, or *dies solis*, in compliance with the ordinary forms of speech, the first day of the week being so called by the Romans, because it was dedicated to the worship of the sun.

SUNDERLAND, a port-town of Durham, situated on the German sea, at the mouth of the river Wear, ten miles north-east of Durham city.

SUNTGOW, a territory in the circle of the upper Rhine in Germany, bounded by Alsace on the north; by the river Rhine, which divides it from the Bisiweg, on the east; by Switzerland on the south; and by Franche-Compte on the west.

SUOVETAURILIA, an ancient Roman sacrifice, so called because it consisted of a pig (*sus*), a sheep, or rather ram (*ovis*), and a bull (*taurus*). They were all males, to denote the masculine courage of the Roman people. It was likewise called *foliularia*, because the animals offered up were always (*folida*) whole or uncut.

SUPERCARGO, a person employed by merchants to go a voyage, and oversee their cargo, or lading, and dispose of it to the best advantage.

SUPERCILIUM, in anatomy. See ANATOMY, p. 294.

SUPEREROGATION, in theology, what a man does beyond his duty, or more than he was commanded to do.

SUPERFETATION, a second, or after conception, happening, when the mother, already pregnant, conceives of

a latter coition; so that she bears at once two fetuses of unequal age and bulk, and is delivered of them at different times. We meet with instances of superfetations in Hippocrates, Aristotle, Du Laurens, &c. But they are said to be much more frequent in hares and sows. Naturalists hold, that female rats are frequently born with young rats in their wombs; and we are told of extraordinary instances of this kind in the female part of the human species, by Bartholine, Mentzelius, and in the history of the Royal Academy of Sciences.

SUPERFICIES, or SURFACE, in geometry, a magnitude considered as having two dimensions; or extended in length and breadth, but without thickness or depth.

SUPERFINE, in the manufactories, a term used to express the superlative fineness of a stuff; thus a cloth, a camlet, &c. are said to be superfine, when made of the finest wool, &c. or when they are the finest that can be made.

SUPERINTENDANT, in the French customs, an officer who has the prime management and direction of the finances or revenues of the king.

SUPERIOR, something raised above another, or that has a right to command another.

SUPERIOR, in Scots law. See LAW, Tit. x. 3.

SUPERLATIVE, in grammar, one of the three degrees of comparison, being that inflection of nouns-adjective that serves to augment and heighten their signification, and shews the quality of the thing denoted to be in the highest degree. See GRAMMAR.

SUPERNUMERARY, something over and above a fixed number. In several of the offices are supernumerary clerks, to be ready on extraordinary occasions.

SUPERSEDEAS in law, is a writ which lies in divers cases, and in general signifies a command to stay some of the ordinary proceedings in law, which, on good cause shewn, ought not to proceed.

SUPERSTITION, extravagant devotion, or religion wrong directed or conducted.

SUPERVISOR, a surveyor or overseer.

It was formerly, and still remains, a custom among some persons, to appoint a supervisor of a will, to see that the executors thereof do punctually observe and perform the same.

SUPINATION, in anatomy, the action of a supinator-muscle, or the motion whereby it turns the hand so as that the palm is lifted up towards heaven.

SUPINATOR, in anatomy. See ANATOMY, p. 198.

SUPPLEMENT, in matters of literature, an appendage to a book, to supply what is wanting therein.

SUPPORTED, in heraldry, a term applied to the uppermost quarters of a shield when divided into several quarters, these seeming as it were supported or sustained by those below. The chief is said to be supported when it is of two colours, and the upper colour takes up two thirds of it. In this case it is supported by the colour underneath.

SUPPORTERS, in heraldry, figures in an achievement placed by the side of the shield, and seeming to support or hold up the same. Supporters are chiefly figures of beasts: figures of human creatures, for the like purpose, are properly called tenants.

SUPPOSITORY, a kind of medicated cone, or ball, which is introduced to the anus for opening the belly. Suppositories

stories are usually made of soap, sugar, alum, or a piece of tallow-candle, about the length of a man's thumb and the breadth of a finger, though they may be made smaller for children, and sometimes a little thicker for adults.

SUPPRESSION, in law, the extinction or annihilating of an office, right, rent, or the like.

SUPPRESSION, in medicine, is generally used for a retention of urine or the menses. See **MEDICINE**, p. 160 162.

SUPPURATION the second way wherein an inflammation terminates, being a conversion of the inflamed blood and the soft adjacent parts, as the vessels and fat, into pus, or matter: which disorder, when it has not yet found an opening, is generally called an abscess. See **MEDICINE**, and **SURGERY**.

SUPPURATIVES, or **SUPPURATING MEDICINES**, such as promote suppuration. See the preceding article.

SUPRACOSTALES, in anatomy. See **ANATOMY**, p. 215.

SUPRALAPSARY, in theology, a person who holds that God, without any regard to the good or evil works of men, has resolved, by an eternal decree, to save some and damn others. These are also called antelapsaries, and are opposed to sublapsaries and infralapsaries.

SUPRASPINATUS, in anatomy. See **ANATOMY**, p. 196.

SUPREMACY, the superiority or sovereignty of the king.

SURAT, a city and port-town of Hither India, in the province of Guzerat, or Cambaya, situated on the river

Tapte, ten miles east of the Indian sea: in E. long. 72° 20', N. lat. 21° 30'.

SURCHARGE, the same with overcharge, and whatever is above that which is just and right.

SURCOAT, a coat of arms to be worn over the body armour.

The surcoat is properly a loose thin taffaty coat, with arms embroidered or painted on it, such as is worn by heralds: anciently also used by military men over their armour, to distinguish themselves by.

SURCULUS, in the anatomy of plants, a word used to express that part of the branching of the ribs of a leaf, which is of a middle kind betwixt the great middle rib and the smallest reticular ramifications.

SURD. See **ALGEBRA**, p. 95.

SURETY, in law, generally signifies the same with bail. See **BAIL**.

SURFACE. See **SUPERFICIES**.

SURFEIT, in medicine, a sickness proceeding from the sensation of a load at the stomach, usually attended with eruptions, and sometimes with a fever. See **MEDICINE**.

SURGE, in the sea-language, the same with wave. See **WAVE**.

Also when heaving at the capitan, if the cable royal or messenger slip a little, they call it surging.

S U R G E R Y.

SURGERY, the art of curing all manner of wounds, and other disorders, where the application of the hand, assisted by proper instruments, is necessary.

OF PHLEBOTOMY.

We begin with the operation of phlebotomy: because it is of all the most general, performed in most parts of the body, and by much the most frequent in use at this present day. By phlebotomy, or bleeding, we here intend the opening a vein, by a sharp-edged and pointed instrument of steel, for extracting a proper quantity of blood, either for the preservation or recovery of a person's health.

It is commonly enough known, that the operation of bleeding in the arm is performed on the veins that lie on the internal part of the cubit. There are several things worthy the surgeon's notice in this operation: some of which regard the things which are to be done preparatory to bleeding, some in the operation itself, others immediately after the performance of it. Preparatory to bleeding you should have in readiness. (1.) A linen fillet, about an ell in length, and two fingers in breadth. (2.) Two small square bolsters. (3.) Pongings or vessels to receive the blood. (4.) A sponge with warm water. (5.) Some vinegar, wine, or Hungary water, to raise the patient's spirits if he should be inclinable to faint. (6.) Two assistants, one to hold the ponging, the other to reach you anything that you shall want. (7.) You must place your patient upon a couch; or, if he is very fearful of the operation, lay him upon a bed, lest he should fall into a swoon. Lastly, the operator should be as expert in bleeding with his left hand as with his right: For,

as you are readier at bleeding in the right arm with your right hand, so when you are to open the veins of the left arm you will find it necessary to use your left hand.

Though the operation is to be performed at once, with one puncture, yet many things are to be observed in order to render it successful. First, it is necessary for the surgeon to inspect his patient's arm diligently, that he may see the course of the veins: he must then take hold of the arm, and extend it towards his breast, tucking up the sleeve about a hand's breadth above the bend of the cubit, where he must make his ligature, rolling the fillet twice round, and fastening it with a knot. The veins being compressed, and the blood being stopped in its return, they will enlarge, and lie fairer to the eye. When you have bound up the arm in this manner, you let it go for a small time till the veins grow turgid. You are then to lay hold of the arm again in the same manner as we directed before, and extend it to your breast, having an assistant ready with the vessel in his hand, at a convenient distance for receiving the blood.

You are now to examine which vein lies fairest, and is therefore most proper to be opened. For you must observe, that in the arm there usually appear three principal veins. The first is called *Vena Cephalica* and is found in the external part of the arm. The second is termed *Basilica*, and lies on the internal part of the arm: In the right arm it is also called *Hepatica*; in the left, *Splenica*. The third, which is obliquely situated between the former two, is called *Mediana*. The median and basilic veins, as they are larger than the cephalic, discharge a greater quantity of blood, but are attended with more danger in the operation:

E.

For a considerable artery and the brachial nerve lie under the basilic vein, and the tendon of the biceps muscle under the median. But as they lie fairer to the eye, and are therefore more frequently the subjects of the operations we are treating of than the cephalic vein, it is safer and more eligible for the less experienced surgeons to open the basilic, or at least the median vein.

When you have determined which vein to open, you are to perform the operation on that part which presents itself fairest to you. But if the vein has frequently been opened, and the part which appears largest and fairest is full of cicatrices, you are not to open above, but below the cicatrices, by which means the blood will discharge itself more freely: For the part above is generally straitened by the cicatrix.

Before you apply the lancet to the skin, when the veins are not risen, it will be proper to rub the arm below the bandage, which will drive the blood back towards the cubit, and render the veins more turgid. Whilst this is doing in the right arm, the surgeon should take hold of the patient's arm in such a manner that he may lay his thumb upon the vein he intends to open, to prevent the blood from flowing back, and to keep the vein from rolling. You are now to fix your eye upon that part of the vein which you intend to open, and taking the lancet with your right hand, so placed that the thumb and first finger may be fixed about the middle of the blade; the other fingers should rest gently upon the patient's arm, to prevent your hand from slipping.

Your lancet is now to be pushed lightly and carefully forward by your thumb and fore-finger, till it has penetrated through the coats of the vein; and at that instant to be raised a little upwards, in order to enlarge the orifice of the wound, which will give a freer passage to the blood. The most common and convenient size of an orifice is about twice the breadth of the back of an ordinary knife. You are to keep even between the two extremes of rashness and timidity in making the puncture. For as in one case you will only divide the common integuments, and so leave your work undone; so in the other you will run the risque of wounding the artery, nerve, or tendon.

Your aperture being thus made, and the instrument drawn instantly back, the blood will then rush forth from the orifice either in a large or small stream. In the mean time the blood must be permitted to flow as long as it shall be judged useful or necessary; and if it should stop too soon, as it often may from too great a stricture of the bandage on the arm, it must be slackened a little, by which means the compressed artery being set at liberty, the blood will flow from the orifice as at first. If you find the orifice obstructed by too great a tension of the skin, or an intrusion of the *membrana adiposa*, you ought in that case to return the bit of fat, by pressing with the finger or a warm sponge, and to relax the skin by bending the arm a little. Lastly, if the orifice be obstructed by thick, grumous, or congealed blood, that impediment may be removed by wiping it with a sponge dipped in warm water.

But that the patient's arm may not become painful or languid, by holding it long extended, the surgeon should support it by the cubitus for a little while; and then give him a stick, or other cylindric body, to turn round in his hand, that by the contractions of the flexor and extensor muscles of the fingers, the course of the blood may be accelerated towards the cubitus: which will still be further promoted, if the patient urges a little voluntary cough.

When there seems to be a sufficient quantity of blood discharged, the ligature must then be immediately taken off from above the elbow, and the skin about the orifice must next be gently stroked or pressed together by the two fore-fingers of the left-hand; by which means the lips of the divided vein are more easily compressed and closed. But while the surgeon is doing this with his left hand, he takes the smallest of the two compresses, and applies it upon the incision with his right-hand: but so as to let what little blood may remain betwixt the orifice and the vein, be discharged, before he imposes the compress. Over the first or smallest compress he should impose another that is a little larger, pressing them both gently on the orifice with his left thumb, till the bandage is laid across.

Having applied your bandage, and drawn down the patient's sleeve over his arm; he should be ordered not to use it too early or violently, before the orifice is well closed, which might excite a fresh hæmorrhage, an inflammation, suppuration, or other bad accident. And if the patient should faint away soon after the operation, it may be then convenient to wet his nostrils with Hungary water or vinegar; and to sprinkle some of the last, or else cold water, in his face; and, especially in summer-time, to let in the fresh and cool air, by opening the windows, &c. Also, if any wine or cordial water be at hand, you may give the languishing patient a small draught thereof.

OF BLEEDING IN THE FOOT.

BLEEDING in the foot is an operation of very old standing: it having been an observation made by the most ancient physicians, that phlebotomy in this part proved highly serviceable in most disorders of the head and breast, and for an obstruction of the menstrual and hæmorrhoidal flux; upon which discharges greatly depended the healthy state of both sexes. For these reasons they therefore denominated those veins of the foot, *Saphena* and *Cephalica*: the last of which extends itself from the internal ancle to the great toe; and the first, from the external *malleolus* to the smaller toes. But why one of them should be thought or denominated more cephalic than the other, there is not the least reason to be offered; since bleeding from either of them has altogether the very same effect. Therefore, the surgeon should always open that which lies fairest and most conspicuous. But if the veins upon the *metatarsus*, or instep of the foot, do not well appear, it may then be convenient to open one of those at the ancle, or about the calf or ham of the leg. Nor is the phlebotomist so liable to injure any of the tendons in these last parts as he is upon the *metatarsus*.

For the more easy and successful apertion of these veins, the patient must first wash both feet well for some time in hot water; that when the veins become sufficiently turgid, the surgeon may take his choice of that which presents fairest either in the right or left foot, without paying any deference to the distinction of right or left in any of the fore-mentioned disorders. Having fixed upon the particular foot and vein, your ligature must be applied about two fingers breadth above the ancle; and then the patient must return it into the warm water, while the surgeon takes out and prepares his instrument or lancet. Then kneeling down on one knee, the surgeon takes out the patient's foot from the warm water, and having wiped it dry with a napkin, places it upon his other knee, or else upon a board laid over the vessel of hot

hot water. He now fastens or secures down the vein from slipping with his left hand. But if the veins do not appear well under the angles, the ligature must be removed higher, about two fingers breadth above where you intend to make the aperture of the vein which best offers itself.

The blood from the vein thus opened may be received into a basin; and if it does not flow freely from the orifice, the foot should be returned into the warm water, which will either prevent or dissolve the congealing of the blood that in this case often obstructs the aperture. When a sufficient quantity of blood has been thus drawn, which may be known partly from the time, and partly from the largeness of the stream, as also from the redness of the water, and condition of strength of the patient, the orifice is then to be closed by the finger, and after drying the foot with a napkin, to be secured by compresses and bandages.

Of Bleeding in the Veins of the Forehead, Temples, and Occiput.

THERE are many physicians and surgeons, who think that bleeding by the veins of the forehead and temples is much more serviceable and expeditious in relieving all disorders of the head, such as violent pains, vertigo, delirium, melancholy, and raving madness, &c. than the like discharge by veins more remote from the parts affected; judging that their vicinity renders them more capable of evacuating the offending matter of the disease. Before proceeding to cut the veins, a handkerchief or neckcloth ought to be drawn tight round the neck; that, by compressing the jugular vein, those branches of it may become more turgid and conspicuous. The vein being opened, the patient must hold down his head, that the blood may not trickle from his forehead into his eyes or mouth, when the stream does not spin out with sufficient force. If the blood does not stop of itself after a due quantity is discharged, you must compress the orifice with your finger; and after wiping the forehead and face, apply a compress or two, and then your bandage.

Bleeding from the occipital veins, which communicate with the lateral sinusses of the *dura mater*, is both by reason and experience proved to be serviceable in most disorders of the brain, where that part is overcharged with blood, which may be this way diverted and evacuated. The celebrated anatomist Morgagni especially recommends it, with scarification and cupping in those parts, for all lethargic disorders.

Of Bleeding in the Jugular Veins of the Neck.

It has been a very ancient practice to bleed in the external jugular veins of the neck, for most inflammatory disorders of the adjacent parts, for a quinsey, phrenzy, madness, ophthalmia, apoplexy, inveterate head-aches, lethargy, and other disorders of the head. Nor are there wanting many among our modern surgeons and physicians to encourage the same practice, and that even from the authority of reason and experience; since the accumulated and obstructed blood and humours may be this way discharged from the parts affected, and their bad consequences prevented. Nor is the operation at all dangerous; since the jugular veins run on each side the neck from the head to the clavicles, immediately under the skin, and appearing generally very large, they may be easily perceived and opened: before which, you must make a stricture upon the lower part of the neck with a handkerchief, or the common ligature,

which must be drawn tight by an assistant or the patient, to make the vein turgid and conspicuous.

When the jugular veins have been by this means rendered turgid and conspicuous, either of them which appears plainest may be secured by the finger for incision, either in the right or left side of the neck indifferently; when the disorder lies in the whole head, or in the neck and fauces. But when only one side of the head, or one eye, is affected, the vein ought to be opened on the disordered side of the neck. The requisite quantity of the blood being taken, the ligature is next removed, and the orifice compressed with your finger, if the blood does not stop without, while you wipe clean the neck, and then apply your compress and circular bandage. Thus the blood stops without any danger of a fresh hæmorrhage. Lastly, it must be acknowledged, that the patient faints away as readily after bleeding in the neck, as the jugular veins are safely and easily opened: but no danger follows from thence.

Of Bleeding in the Veins, called Ranula, under the Tongue.

It is very often found of no small service in a quinsey, or other inflammatory disorder of the neck, to bleed in the two small veins which run under the tip or end of the tongue: especially if a larger vein has been opened before, either in the neck, foot, or arm, whereby the impurified and stagnated blood may be gradually evacuated. To bleed in these veins, a stricture being made upon the neck as before, you then elevate the apex of the tongue with your left hand, while, with the lancet in your right you circumspically open first one, and then the other on each side; because the aperture of one only will hardly ever discharge blood enough to give any considerable relief. When you judge a sufficient quantity of blood has run out of the mouth into your vessel, remove the ligature from the neck: upon which the flux usually stops of itself. But if it should still continue, let the patient take a little vinegar or *Frontinac* wine in his mouth: or else you may apply a bit of vitriol or alum, or a compress dipt in some styptic liquor, till the hæmorrhage ceases; which can never be dangerous even without such topics.

Of Phlebotomy in the Penis.

Bleeding in the *vena dorsalis penis* usually surpasses the benefit of all remedies whatever in abating inflammatory disorders of this member. This large vein, which runs along the back or upper side of the penis, being generally pretty much dilated, and conspicuous in an inflammation of this part, may be incised about the middle or back part of the penis; and kept bleeding till the member becomes flaccid, and a sufficient quantity of blood be discharged proportionable to the urgency of the symptoms. This done, you must apply a compress, and the bandage proper for the penis. But you must carefully endeavour to avoid injuring the arteries or nerves which enter the penis near this vein; as also not to make your bandage too strict: for by these means the inflammation and symptoms may turn out worse than before.

Of Wounds.

To conceive rightly of the nature and treatment of wounds, under the variety of disorders that they are subject to, it will be proper first to learn, what are the appearances in

the progress of healing a large wound, when it is made with a sharp instrument, and the constitution is pure.

In this circumstance, the blood-vessels, immediately upon their division, bleed freely, and continue bleeding till they are either stopped by art, or at length contracting and withdrawing themselves into the wound, their extremities are shut up by the coagulated blood. The hæmorrhage being stopped, the next occurrence, in about twenty-four hours, is a thin serous discharge: and, a day or two after, an increase of it, though somewhat thickened, and thickening. In this state it continues two or three days without any great alteration, from which time the matter grows thicker and less offensive; and when the bottom of the wound fills up with little granulations of flesh, it diminishes in its quantity, and continues doing so till the wound is quite skinned over.

The first stage of healing, or the discharge of matter, is by surgeons called *digestion*: the second or the filling up by *flesh*, *incarnation*; and the last, or skinning over, *cicatization*.

It is worth observing, that the loss of any particular part of the body can only be repaired by the fluids of that distinct part; and as in a broken bone, the *callus* is generated from the ends of the fracture, so, in a wound, is the cicatrix from the circumference of the skin only: Hence arises the necessity of keeping the surface even, either by pressure or eating medicaments, that the eminence of the flesh may not resist the fibres of the skin in their tendency to cover the wound. This eminence is composed of little points or granulations called *fungus*, or proud flesh, and is frequently esteemed an evil, though in truth this species of it be the constant attendant on healing wounds; for when they are smooth, and have no disposition to shoot out above their lips, there is a slackness to heal, and a cure is very difficultly effected. Since then a *fungus* prevents healing only by its luxuriancy, and all wounds cicatrize from their circumference, there will be no occasion to destroy the whole *fungus* every time it rises, but only the edges of it near the lips of the skin; which may be done by gentle escharotics, such as lint dipped in a mild solution of *vitriol*, or for the most part only by dry lint, and a tight bandage, which will reduce it sufficiently to a level, if applied before the *fungus* have acquired too much growth. In large wounds, the application of corrosive medicines to the whole surface, is of no use; because the *fungus* will attain but to a certain height, when left to itself, which it will be frequently rising up to, though it be often wasted; and as all the advantage to be gathered from it, is only from the evenness of its margin, the purpose will be as fully answered by keeping that under only, and an infinite deal of pain avoided from the continual repetition of escharotics.

From what has been said of the progress of a wound made by a sharp instrument, where there is no indispotion of body, we see the cure is performed without any interruption, but from the *fungus*; so that the business of surgery will consist principally in a proper regard to that point, and in applications that will the least interfere with the ordinary course of nature, which in these cases will be such as act the least upon the surface of the wound; and agreeably to this we find, that dry lint only is generally the best remedy through the whole course of dressing: at first, it stops the blood with less injury than any styptic powders or waters; and afterwards, by absorbing the matter, which in the be-

ginning of suppuration is thin and acrimonious, it becomes in effect a digestive: during incarnation it is the softest medium that can be applied between the roller and tender granulations, and at the same time is an easy compress upon the sprouting *fungus*.

Over the dry lint, may be applied a pledget of some soft ointment spread upon tow, which must be renewed every day, and preserved in its situation by a gentle bandage; though in all large wounds, the first dressing, after that of the accident or operation, should not be applied in less than three days, when, the matter being formed, the lint separates more easily from the part; in the removal of which, no force should be used, but only so much be taken away as is loose and comes off without pain.

Of INFLAMMATIONS and ABSCESSSES.

As almost all abscesses are the consequences of inflammations, and these produce a variety of events, as they are differently complicated with other disorders, it will be proper first to make some inquiry into their disposition. Inflammations from all causes have three ways of terminating; either by dispersion, suppuration, or gangrene.

But though every kind of inflammation will sometimes terminate in different shapes, yet a probable conjecture of the event may be always gathered from the state of the patient's health. Thus inflammations happening in a slight degree upon colds, and, without any foregoing indisposition, will most probably be dispersed: those which follow close upon a fever, or happen to a very gross habit of body, will generally impothumate: and those which fall upon very old people, or dropical constitutions, will have a strong tendency to gangrene.

In the state of an inflammation be such as to make the dispersion of it safely practicable, that end will be best brought about by evacuations, such as plentiful bleeding and repeated purges: the part itself must be treated with fomentations twice a-day; and if the skin be very tense, it may be embrocated with a mixture of three fourths of oil of roses, and one fourth of common vinegar, and afterwards be covered with *unguent for Jamb.* or a soft ointment made of white wax and sweet oil, spread upon a fine rag, and rolled on gently. If after four or five days, the inflammation begin to subside, the purging waters and manna may take place of other purges, and the embrocation of oil and vinegar be now omitted, or sooner if it has begun to excoriate. The ointment of wax and oil may be continued to the last. During the cure a thin diet is absolutely necessary, and in the height of the inflammation the drinking of thin liquors is of great service.

Here we have supposed that the inflammation had so great a tendency to diffusion, as, by the help of proper assistance, to terminate in that manner; but when it happens that the disposition of the tumour resists all discutient means, we must then desist from any farther evacuations, and assist nature in the bringing on a suppuration.

That matter will most likely be formed, we may judge from the increase of the symptomatic fever, and enlargement of the tumour, with more pain and pulsation; and if a small rigor come on, it is hardly to be doubted. Inflammations after a fever, and the small-pox, almost always suppurate; but these presently discover their tendency, or at least should be at first gently treated, as though we expected an impothumation. It is a maxim laid down in surgery,

very, that evacuations are pernicious in every circumstance of a disease, which is at last to end in suppuration: But as physicians do now acknowledge, that bleeding on certain occasions in the small-pox, is not only no impediment to the maturation, but even promotes it; so in the formation of abscesses, when the vessels have been clogged, and the suppuration has not kindly advanced, bleeding has sometimes quickened it accordingly; but, however, this practice is to be followed with caution. Purgés are, no doubt, improper at this time; yet if the patient be collive, he must be assisted with gentle clysters every two or three days.

Of all the applications invented to promote suppuration, there are none so easy as poultices; but as there are particular tumours very slow of suppuration, and almost void of pain (such, for instance, are some of the scrophulous swellings) it will be less troublesome in these cases to wear the gum-plasters, which may be renewed every four or five days only. Amongst the suppurative poultices perhaps there is none preferable to that made of bread and milk softened with oil; at least the advantage of any other over it is not to be distinguished in practice. The abscess may be covered with the poultice twice a-day, till it come to that ripeness as to require opening, which will be known by the thinness and eminence of the skin in some part of it, a fluctuation of the matter, and generally speaking, an abatement of the pain previous to these appearances.

The signs of a gangrene are these: the inflammation loses its redness, and becomes dusky and livid; the tenderness of the skin goes off, and feels to the touch flabby or emphysematous; vesications filled with ichor of different colours spread all over it; the tumour subsides, and, from a dusky complexion, turns black: the pulse quickens and sinks, and profuse sweats coming on, at last grow cold, and the patient dies.

To stop the progress of a mortification, the method of treatment will be nearly the same, from whatever cause it proceed, except in that arising from cold; in which case, we ought to be cautious not to apply warmth too suddenly to the part, if it be true, that in the northern countries they have daily conviction of gangrenes produced by this means, which might have been easily prevented by avoiding heat; nay, they carry their apprehension of the danger of sudden warmth so far as to cover the part with snow first, which they say seldom fails to obviate any ill consequence.

The practice of scarifying gangrenes, by several incisions, is almost universal; and with reason; since it not only lets the parts free, and discharges a pernicious ichor, but makes way for whatever efficacy there may be in topical applications. These are different with different surgeons: but the digestives softened with oil of turpentine are as good dressings as any for the scarifications: and upon them all over the part, may be laid the *theriaca Londinensis*, which should be always used in the beginning of a gangrene before the necessity of scarifying arises; or what is equally good, if not often preferable, a cataplasm made with lixivium and bran, and applied warm, which will retain its heat better than most other topicals. Medicines also given internally are beneficial, and these should consist of the cordial kind; but the bark is the sovereign remedy for this disorder: after the separation of the eschar, the wound becomes a common ulcer, and must be treated as such.

There are two ways of opening an abscess; either by incision, or caustick; but incision is preferable in most cases.

In small abscesses, there is seldom a necessity for greater dilatation than a little orifice made with the point of a lancet; and in large ones, where there is not a great quantity of skin discoloured and become thin, an incision to their utmost extent will usually answer the purpose; or if there be much thin discoloured skin, a circular or oval piece of it must be cut away; which operation, if done dexterously with a knife, is much less painful than by caustick, and at once lays open a great space of the abscess, which may be dressed down to the bottom, and the matter of it be freely discharged; whereas, after a caustick, though we make incisions through the eschar, yet the matter will be under some confinement; and we cannot have the advantage of dressing properly till the separation of the slough, which often requires a considerable time, so that the cure must be necessarily delayed; besides that the pain of burning continuing two or three hours, which a caustick usually requires in doing its office, draws such a fluid upon the skin round the eschar, as sometimes to indispose it very much, or healing afterwards. In the use of causticks, it is but too much a practice, to lay a small one on the most prominent part of a large tumour, which not giving sufficient vent to the matter, and perhaps the orifice soon after growing narrow, leads on to the necessity of employing tents; which two circumstances more frequently make fistulas after an abscess, than any malignity in the nature of the abscess itself. The event would more certainly be the same after a small incision; but surgeons not depending so much on small openings by incision, as by caustick, do, when they use the knife, generally dilate sufficiently: whereas, in the other way, a little opening in the most depending part of the tumour usually satisfies them.

From this account of the method of opening abscesses, it does not appear often necessary to apply causticks; yet they have their advantages in some respects, and are seldom so terrible to patients as the knife, though in fact they are frequently more painful to bear. They are of most use in cases where the skin is thin and inflamed: and we have reason to think the malignity of the abscess is of that nature as to prevent a quickness of incarning; in which circumstance, if an incision only were made through the skin, little sinusses would often form, and burrow underneath, and the lips of it lying loose and flabby, would become callous, and retard the cure, though the malignity of the wound were corrected of this kind, are venereal buboes, which notwithstanding they often do well by mere incision, yet when the skin is in the state we have supposed, the caustick is always preferable: but this method should be confined to venereal buboes; for those which follow a fever, or the small-pox, for the most part are curable by incision only. There are many scrophulous tumours, where the reasoning is the same as in the venereal: and even in great swellings, if the patient will not submit to cutting, and the surgeon is apprehensive of any danger in wounding a large vessel, which is often done with the knife, yet as this inconvenience is avoided by caustick, it may on such an occasion be made use of; however, in scrophulous swellings of the neck and face, unless they are very large, causticks are not adviseable, since in that part of the body, with length of time, they heal after incision. Causticks are of great service in destroying stubborn scrophulous indurations of the glands, also venereal indurations of the glands of the groin, which will neither disengage nor suppurate; likewise in exposing carious bones, and making,

making large issues. The best caustick in use is a paste made with lime and *liviūm capitale*, which is to be prevented from spreading, by cutting an orifice in a piece of sticking plaster, nearly as big as you mean to make the eschar; which being applied to the part, the caustick must be laid on the orifice, and preserved in its situation by a few slips of plaster laid round its edges, and a large piece over the whole. When issues are made, or bones exposed, the eschar should be cut out immediately, or the next day: for if we wait the separation, we miscarry in our design of making a deep opening; since sloughs are flung off by the sprouting new flesh underneath, which fills up the cavity at the same time that it discharges the eschar; so that we are obliged afterwards to make the opening a second time with painful escharotick medicines. To make an issue or lay a bone bare, this caustick may lie on about four hours; to destroy a large gland, five or six; and to open abscesses, an hour and a half, two hours, or three hours, according to the thickness of the skin; and what is very remarkable, notwithstanding its strength and sudden efficacy, it frequently gives no pain where the skin is not inflamed, as in making issues, and opening some few abscesses.

When an abscess is already burst, we are to be guided by the probe where to dilate, observing the same rules with regard to the degree of dilatation as in the other case. The usual method of dilating, is with the probe-scissars; and indeed, in all abscesses, the generality of surgeons use the scissars, after having first made a puncture with a lancet; but as the knife operates much more quickly, and with less violence to the parts, than scissars, which squeeze at the same time that they wound, it will be sparing the patient a great deal of pain to use the knife, where-ever it is practicable, which is in almost all cases, except some fistula's *in ano*, where the scissars are more convenient. The manner of opening with a knife, is by sliding it on a director, the groove of which prevents its being misguided. If the orifice of the abscess be so small as not to admit the director, or the blade of the scissars, it must be enlarged by a piece of sponge-tent; which is made by dipping a dry bit of sponge in melted wax, and immediately squeezing as much out of it again as possible, between two pieces of tile or marble; the effect of which is, that the loose sponge being compressed into a small compass, if any of it be introduced into an abscess, the heat of the part melts down the remaining wax that holds it together, and the sponge sucking up the moisture of the abscess, expands, and in expanding opens the orifice wider, and by degrees, so as to give very little pain.

The usual method of dressing an abscess, the first time, is with dry lint only; or if there be no flux of blood, with soft digestives spread on lint. If there be no danger of the upper part of the wound uniting too soon, the dossils must be laid in loose; but if the abscess be deep, and the wound narrow, as is the case sometimes of abscesses *in ano*, the lint must be crammed in pretty tightly, that we may have afterwards the advantage of dressing down to the bottom without the use of tents, which, by resisting the growth of the little granulations of flesh, in process of time harden them, and in that manner produce a fistula; so that, instead of being used for the cure of an abscess, they never should be employed but where we mean to retard the healing of the external wound, except in some little narrow abscesses, where, if they be not crammed in too large, they become as dossils, admitting of incarnation at the bottom; but care

should be taken, not to infiltrate them much deeper than the skin in this case, and that they should be repeated twice a day, to give vent to the matter they confine. But tents do most good in little deep abscesses, whence any extraneous body is to be evacuated, such as small splinters of bone, &c.

The use of vulnerary injections into abscesses has been thought to bear so near a resemblance to the use of tents, that they both fell into disrepute almost at the same time.

Over the dossils of lint may be laid a large pledget of tow spread with balsam, which will lie softer than a desiccative plaster; for this, though designed to defend the circumference of wounds against inflammation or a fluxion of humours, is often the very cause of them; so that the dressings of large wounds should never be kept on by these plasters, where there is danger of such accidents. In this manner, the dressings may be continued, till the cavity is incarnated; and then it may be cicatrised with dry lint, or some of the cicatrifying ointments, observing to keep the fungus down, as directed before.

In the course of dressing it will be proper to have regard to the situation of the abscess, and as much as possible to make the patient favour the discharge by his ordinary posture: and to this end also, as what is of greater importance than the virtue of any ointment, the discharge must be assisted by compress and bandage: the compress may be made of rags or plaster; though the latter is sometimes preferable, as it remains immovable on the part it is applied to. The frequency of dressing will depend on the quantity of discharge: once in twenty-four hours is ordinarily sufficient; but sometimes twice, or perhaps three times, is necessary.

Of ULCERS.

WHEN a wound or abscess degenerates into so bad a state as to resist the methods of cure above laid down, and loses that completion which belongs to a healing wound, it is called an ulcer, and as the name is generally borrowed from the ill habit of the fore, it is a custom to apply it to all sores that have any degree of malignity, though they be immediately formed without any previous abscess or wound; such are the venereal ulcers of the gonoids, &c.

Ulcers are distinguished by their particular disorders, though it seldom happens that the affections are not complicated, and when we lay down rules for the management of one species of ulcer, it is generally requisite to apply them to almost all others. However, the characters of most eminence are, the callous ulcer, the sinous ulcer, and the ulcer with caries of the adjacent bone; tho' there be abundance more known to surgeons, such as the putrid, the corrosive, the varicous, &c. but as they have acquired their names from some particular affection, we shall speak of the treatment of them under the general head of ulcers.

It will be often in vain to pursue the best means of cure by topical application, unless we are assisted by internal remedies; for as many ulcers are the effects of a particular indispotion of body, it will be difficult to bring them into order, while the cause of them remains with any violence; though they are sometimes in a great degree the discharge of the indispotion itself, as in the plague, small-pox, &c. But we see it generally necessary in the pox, the scurvy, obstructions of the menses, dropsies, and many other distempers, to give internals of great efficacy; and indeed, there are hardly any constitutions where ulcers are not assisted by some physical regimen. Those that are cancerous and

and scrophulous seem to gain the least advantage from physic; for if in their beginnings they have sometimes very much relieved, or cured, by salivation, or any other evacuation, they are also often irritated and made worse by them; so that there is nothing very certain in the effects of violent medicines in these distempers. Upon the whole, in both these cases, the milk-diet, and gentle purgings with manna, and the waters, seem to be most efficacious; though brisk methods may be used with more safety in the evil than in the cancer; and sometimes, particularly in young subjects, the decoction of the woods is extremely beneficial for scrophulous ulcers: but it has lately been attested by men of great skill and veracity, that sea-water is more powerful than any other remedy hitherto known, both for scrophulous ulcers, and scrophulous tumours.

When an ulcer becomes foul, and discharges a nasty thin ichor, the edges of it, in process of time, tuck in, and growing skinned and hard, give it the name of a callous ulcer, which, so long as the edges continue in that state, must necessarily be prevented from healing: But we are not immediately to destroy the lips of it, in expectation of a sudden cure; for while the malignity of the ulcer remains, which was the occasion of the callosity, so long will the new lips be subject to a relapse of the same kind: however often the external surface of them be destroyed: so that when we have to deal with this circumstance, we are to endeavour to bring the body of the ulcer into a disposition to recover by other methods. It sometimes happens to poor laborious people, who have not been able to afford themselves rest, that lying a-bed will in a short time give a diversion to the humours of the part, and the callous edges softening, will without any great assistance shoot out a cicatrix, when the ulcer is grown clean and filled with good flesh: the effect of a salivation is generally the same; and even an issue does sometimes dispose a neighbouring ulcer to heal: but though callosities be frequently softened by these means, yet when the surface of the ulcer begins to yield thick matter, and little granulations of red flesh shoot up, it will be proper to quicken nature by destroying the edges of it, if they remain hard. The manner of doing this, is by touching them a few days with the lunar caustick, or *lapis infernalis*; and some chuse to cut them off with a knife: but this last method is very painful, and not more efficacious: though when the lips do not tuck down close to the ulcer, but hang loose over it, as in some venereal buboes, where the matter lies a great way under the edges of the skin, the easiest method is cutting them off with the scissars.

To digell the ulcer, or to procure good matter from it when in a putrid state, there are an infinity of ointments invented; but the *Basilicon Flavum* alone, or softened down sometimes with turpentes, and sometimes mixt up with different proportions of red precipitate, seems to serve the purposes of bringing an ulcer on to cicatrification as well as any of the others. When the ulcer is incarnated, the cure may be finished as in other wounds; or if it do not cicatrise kindly, it may be washed with *Aq. Calcis*, or *Aq. Phag.* or dressed with a pledgit dipt in *Tinct. Myrræ*: and if excoriations are spread round the ulcer, they may be anointed with *Sperm. Cet.* ointment, or *Unguent. Nutritum*.

The *Red Precipitate* has of late years acquired the credit it deserves for the cure of ulcers; but by falling into general use, is very often unskillfully applied: when mixed with the *Basilicon*, or, what is nearer, a cerate of wax and oil, it is

most certainly a digestive, since it hardly ever fails to make the ulcer yield a thick matter in twenty-four hours, which discharged a thin one before the application of it.

If the ulcer should be of such a nature as to produce a spongy flesh, sprouting very high above the surface, it will be necessary to destroy it by some of the escharotics, or the knife. This fungus differs very much from that belonging to healing wounds, being more eminent and lax, and generally in one mass; whereas the other is in little distinct protuberances. It approaches often towards a cancerous complexion, and when it rises upon some glands does actually degenerate sometimes into a cancer. When these excrescences have arisen in venereal ulcers, escharotics should be applied. Those in use, are the *Vitriol*, the *Lunar Caustick*, the *Lapis Infernalis*, and more generally the red *Precipitate* powder.

It is but seldom, that these inveterate fungules appear on an ulcer; but it is very useful for those of a milder kind to rise, which may often be made to fuse with pressure, and the use of mild escharotics: however, if the aspect of the fore be white and smooth, as happens in ulcers accompanied with a dropsy, and often in young women with obstructions, it will answer no purpose to waste the excrescences, until the constitution is repaired, when most probably they will sink without any assistance. In ulcers also, where the subjacent bone is carious, great quantities of loose flabby flesh will grow up above the level of the skin: but as the caries is the cause of the disorder, it will be in vain to expect a cure of the excrescence, until the rotten part of the bone be removed; and every attempt with escharotics will be only a repetition of pain to the patient without any advantage.

When the excrescence is cancerous, and does not rise from a large cancer, but only from the skin itself, it has been usual to recommend the actual cautery, but it is better to cut away quite underneath, and dress afterwards with easy applications. As to the treatment of incurable cancerous ulcerations, after much trial, surgeons have at last discovered, that what gives the most ease to the fore is the most suitable application; and therefore the use of escharotics is not to be admitted on any pretence whatsoever; nor in those parts of a cancer that are corroded into cavities, must the precipitate be made use of to procure digestion, or promote the separation of the sloughs. The best way, therefore, is to be guided by the patient what medicine to continue. Those usually prescribed are preparations from lead; but what we have found most beneficial, have been sometimes dry lint alone when it does not stick to the cancer; at other times, lint doiled spread with *Basilicon* or *Cerat. de Lapid. Calam.* and oftener than either with a *Cerate* made of oil and wax, or the *Sperm. Cet.* ointment; and over all, a pledgit of tow spread with the same. Embrocating the neighbouring skin and edges of it with milk, is of service; but the chief good is to be acquired by diet, which should be altogether of milk and things made of milk, though herbage may be admitted also. Issues in the shoulders or thighs do also alleviate the symptoms; and manna, with the purging waters, once, or perhaps twice a-week, will serve to keep the body cool.

When ulcers or abscesses are accompanied with inflammation and pain, they are to be assisted with fomentations made of some of the dry herbs, such as Roman wormwood, bay-leaves, and rosemary; and when they are very putrid and corrosive, which circumstances give them the name of foul phagedenic ulcers, some spirits of wine should be added to the fomentation, and the bandage be also dipt in brandy

or spirits of wine, observing in these cases where there is much pain, always to apply gentle medicines till it be removed.

When the pain and inflammation are excessive, bleeding and other evacuations will often be serviceable; and above all things, rest and a horizontal position, which last circumstance is of great importance to the cure of ulcers of the legs, that unless the patient will conform to it strictly, the skill of the surgeon will often avail nothing; for as the indispotion of these sores is in some measure owing to the gravitation of the humours downwards, it will be much more beneficial to lie along than sit upright, though the leg be laid on a chair; since even in this posture they will descend with more force, than if the body was reclined.

In ulcers of the legs, accompanied with varices or dilatations of the veins, the method of treatment will depend upon the other circumstances of the sore; for the varix can only be assisted by the application of bandage, which must be continued a considerable time after the cure. The nearest bandage is the strait stocking, which is particularly serviceable in this case; though also, if the legs be *œdematous*, or, if, after the healing of the ulcers, they swell when the patient quits his bed, it may be worn with safety and advantage. There are instances of one vein only being varicous, which when it happens, may be destroyed by tying it above and below the dilation, as in an aneurism; but this operation should only be practised where the varix is large and painful.

Ulcers of many years standing are very difficult of cure; and in old people the cure is often dangerous, frequently exciting an asthma, a diarrhoea, or a fever, which destroys the patient, unless the sore break out again. So that it is not altogether advisable to attempt the absolute cure in such cases, but only the reduction of them into better order, and less compass, which, if they be not malignant, is generally done with rest and proper care. The cure of those in young people may be undertaken with more safety; but we often find it necessary to raise a salivation to effect it, though, when completed, it does not always last; so that the prospect of cure in stubborn old ulcers, at any time of life, is but indifferent. In all these cases, however, it is proper to purge once or twice a-week with calomel, if the patient can bear it, and to make an issue when the sore is almost healed, in order to continue a discharge the constitution has been so long habituated to, and prevent its falling from the cicatrix, and bursting out again in that place.

When an ulcer or abscess has any sinuses or channels opening and discharging themselves into the sore, they are called sinuous ulcers. These sinuses, if they continue to drain a great while, grow hard in the surface of their cavity, and then are termed fistule, and the ulcer a fistulous ulcer; also, if matter be discharged from any cavity, as those of the joints, abdomen, &c. the opening is called a sinuous ulcer, or a fistula.

The treatment of these ulcers depends upon a variety of circumstances. If the matter of the sinus be thick, thick bandage and compress will sometimes bring the opposite sides of the sinus to a re-union: if the sinus grow turgid in any part, and the skin thinner, shewing a disposition to break, the matter must be made to push more against that part, by plugging it up with a tent; and then a counter-opening must be made, which proves often sufficient for the whole abscess, if it be not afterwards too much tented, which locks up the matter and prevents the healing; or

too little, which will have the same effect; for dressing quite superficially, does sometimes prove as mischievous as tents, and for nearly the same reason, since suffering the external wound to contract into a narrow orifice before the internal one be inclosed, does almost as effectually lock up the matter as a tent: to preserve then a medium in these cases, a hollow tent of lead or silver may be kept in the orifice, which, at the same time that it keeps it open, gives vent to the matter. The abscesses where the counter opening are made most frequently, are those of compound fractures, and the breast; but the latter do often well without dilatation than the former, though it must be performed in both, if practicable, the whole length of the abscess, when after some trial the matter does not lessen in quantity, and the sides of it grow thinner; and if the sinuses be fistulous, there is no expectation of cure without dilation. There are also a great many scrophulous abscesses of the neck, that sometimes communicate by sinuses running under large indurations; in which instances, counter-openings are advisable, and generally answer without the necessity of dilating the whole length; and indeed there are few abscesses in this distemper, which should be opened beyond the thinness of the skin. When abscesses of the joints discharge themselves, there is no other method of treating the fistula, but by keeping it open with the cautions already laid down, till the cartilages of the extremities of the bones being corroded, the two bones shoot into one another, and form an ankylosis of the joint, which is the most usual cure of ulcers in that part.

Gun-shot wounds often become sinuous ulcers and then are to be considered in the same light as those already described; though surgeons have been always inclined to conceive there is something more mysterious in these wounds than any others; but their terribleness is owing to the violent contusion and laceration of the parts, and often to the admission of extraneous bodies into them, as the bullet, splinters, clothes, &c. and were any other force to do the same thing, the effect would be exactly the same as when done by fire-arms. The treatment of these wounds consists in removing the extraneous body as soon as possible; to which end the patient must be put into the same posture as when he received the wound: if it cannot be extracted by cutting upon it, which should always be practised when the situation of the blood-vessels, &c. does not forbid, it must be left to nature to work out, and the wound dressed superficially; for we must not expect, that if it be kept open with tents, the bullet, &c. will return that way; and there is hardly any case where tents are more pernicious than here, because of the violent tension and disposition to gangrene which presently ensue. To guard against mortification in this, and all other violently contused wounds, it will be proper to bleed the patient immediately, and soon after give a clyster: the part should be dressed with soft digestives, and the compress and roller applied very loose, being first dipped in brandy or spirits of wine. The next time the wound is opened, if it be dangerous, the spirituous fomentation may be employed, and after that continued till the danger is over. If a mortification comes on, the applications for that disorder must be used. In gun-shot wounds, it seldom happens that there is any effusion of blood, unless a large vessel be torn; but the bullet makes an eschar, which usually separates in a few days, and is followed with a plentiful discharge; but when the wound is

come

come to this period, it is manageable by the rules already laid down.

When an ulcer with loose rotten flesh discharges more than the size of it should yield, and the discharge is oily and stinking, in all probability the bone is carious; which may easily be distinguished by running the probe through the flesh: and if so, it is called a carious ulcer. The cure of these ulcers depends principally upon the removal of the rotten part of the bone, without which it will be impossible to heal; as we see sometimes even in little sores of the lower jaw, which taking their rise from a rotten tooth, will not admit of cure till the tooth be drawn. Those caries which happen from the matter of abscesses lying too long upon the bone, are most likely to recover: those of the pox very often do well, because that distemper fixes ordinarily upon the middle and outside of the densest bones, which admit of exfoliation; but those produced by the evil, where the whole extremities of spongy parts of the bone are affected, are exceedingly dangerous, though all enlarged bones be not necessarily carious; and there are ulcers sometimes on the skin that covers them, which do not communicate with the bone and consequently do well without exfoliation: nay, it sometimes happens, though the case be rare, that, in young subjects particularly, the bones will be carious to such a degree, as to admit a probe almost thro' the whole substance of them, and yet afterwards admit of a cure, without any notable exfoliation.

The method of treating an ulcer with a caries, is by applying a caustick of the size of the scale of the bone that is to be exfoliated, and after having laid it bare, to wait till such time as the carious part can, without violence, be separated, and then heal the wound. In order to quicken the exfoliation, there have been several applications devised; but that which has been most used in all ages, is the actual cautery, with which surgeons burn the naked bone every day, or every other day, to dry up, as they say, the moisture. And by that means procure the separation: but as this practice is never of great service, and always cruel and painful, it is now pretty much exploded. Indeed, from considering the appearance of a wound, when a scale of bone is taken out or it, there is hardly any question to be made, but that burning retards rather than hastens the separation; for as every scale of a carious bone is slung off by new flesh generated between it and the sound bone, whatever would prevent the growth of these granulations, would also in a degree prevent the exfoliation; which must certainly be the effect of a red hot iron applied so close to it; though the circumstances of carious bones, and their disposition to separate, are so different from one another, that it is hardly to be gathered from experience, whether they will sooner exfoliate with or without the assistance of fire: for sometimes, in both methods, an exfoliation is not procured in a twelve month, and at other times it happens in three weeks or a month: however, if it be only uncertain whether the actual cautery be beneficial or not, the cruelty that attends the use of it should entirely banish it out of practice. It is often likewise, in these cases, employed to keep down the fungous lips that spread upon the bone: but it is much more painful than these caustic medicines; though there will be no need of either, if a regular compress be kept on the dressing; or at worst, if a flat piece of the prepared sponge, of the size of the ulcer, be rolled on with a tight bandage, it will swell on every side, and dilate the ulcer without any pain.

Some caries of the bones are so very shallow, that they crumble insensibly away, and the wound fills up; but when the bone will neither exfoliate nor admit of granulations, it will be proper to scrape it with a ruginé, or perforate it in many points with a convenient instrument down to the quick. In the evil, the bones of the *carpus* and *tarfus* are often affected, but their sponginess is the reason that they are seldom cured: so that when these, or indeed the extremities of any of the bones, are carious through their sponginess, it is advisable to amputate: though there are instances in the evil, but more especially in critical abscesses, where after long dressing down, the splinters, and sometimes the whole substance of the small bones, have worked away, and a healthy habit of body coming on, the ulcer has healed; but these are so rare, that no great dependence is to be laid on such an event. The dressings of carious bones, if they are stinking, may be dissolved in the tincture of myrrh; otherwise those of dry lint are easiest, and keep down the edges of the ulcer better than any other gentle applications.

Burns are generally esteemed a distinct kind of ulcers, and have been treated with a greater variety of applications than any other species of sore.

When burns are very superficial, not raising suddenly any vesication, spirits of wine are said to be the quickest relief; but whether they be more serviceable than embrocations with linseed oil, is uncertain, though they are used very much by some persons whose trade subjects them often to this misfortune. If the burn excoriates, it is easiest to roll the part up gently with bandages dipped in sweet oil, or a mixture of *unguent. for sambu.* with the oil: when the excoriations are very tender, dropping warm milk upon them every dressing is very comfortable; or if the patient can bear to have flannels wrung out of it, applied hot, it may be still better: if the burn have formed eschars, they may be dressed with *balsicon*, though generally oil alone is easier; and in these sores, whatever is the easiest medicine will be the best digestive. There is great care necessary to keep down the *fungus* of burns, and heal the wounds smooth: to which end, the edges should be dressed with lint dipped in *aque. virid.* and dried afterwards; or they may be touched with the vitriol-stone, and the dressings be repeated twice a day. There is also a greater danger of contractions from burns after the cure, than from other wounds: to obviate which, embrocations of neat-foot oil, and bandage with pasteboards to keep the part extended, are absolutely necessary, where they can be applied.

EXPLANATION of Plate CLVII. fig. 1.

A. A director by which to guide the knife in the opening of abscesses that are burst of themselves, or first punctured with a lancet. This instrument should be made either of steel, silver, or iron; but so tempered, that it may be bent and accommodated to the direction of the cavity. It is usually made quite straight; but that form prevents the operator from holding it firmly while he is cutting. The manner of using it is, by passing the thumb through the ring, and supporting it with the fore finger, while the straight-edged knife is to slide along the groove with its edge upwards, towards the extremity of the abscess.

B. The straight-edged knife, proper for opening abscesses with the assistance of a director; but which, in few other respects, is preferable to the round-edged knife.

C. A crooked needle, with its convex and concave sides sharp:

sharp: this is used only in the suture of the tendon, and is made thin, that but few of the fibres of so slender a body as a tendon may be injured in the passing of it. This needle is large enough for stitching the *tendo Achillis*.

D, The largest crooked needle necessary for the tying of any vessels, and should be used with a ligature of the size it is threaded with in taking up the spermatic vessels in castration, or the femoral and humeral arteries in amputation. This needle may also be used in sewing up deep wounds.

E, A crooked needle and ligature of the most useful size, being not much too little for the largest vessels, nor a great deal too big for the smallest; and therefore in the taking up of the greatest number of vessels in an amputation, is the proper needle to be employed. This needle also is of a convenient size for sewing up moist wounds.

F, A small crooked needle and ligature for taking up the lesser arteries, such as those of the scalp, and those of the skin that are required in opening abscesses.

Great care should be taken by the makers of these needles, to give them a due temper: for if they are too soft the force sometimes exerted to carry them through the flesh, will bend them; if they are too brittle, they snap; both which accidents may happen to be terrible inconveniences, if the surgeon be not provided with a sufficient number of them. It is of great importance also to give them the form of part of a circle, which makes them pass much more readily round any vessel, than if they were made partly of a circle, and partly of a straight line, and in taking up vessels at the bottom of a deep wound is absolutely necessary, it being impracticable to turn the needle with a straight handle, and bring it round the vessel when in that situation. The convex surface of the needle is flat, and its two edges are sharp. Its concave side is composed of two surfaces, rising from the edge of the needle, and meeting in a ridge or eminence, so that the needle has three sides. The best materials for making ligatures, are the flaxen thread that shoemakers use; which is sufficiently strong when four, six, or eight of the threads are twisted together and waxed; and is not so apt to cut the vessels, as threads that are more finely spun.

G, A straight needle, such as glovers use, with a three-edged point, useful in the uninterrupted suture, in the suture of tendons, where the crooked one *C*, is not preferred, and in sewing up dead bodies, and is rather more handy for taking up the vessels of the scalp.

Of Sutures.

WHEN a wound is recent, and the parts of it are divided by a sharp instrument, without any farther violence, and in such a manner that they may be made to approach each other, by being returned with the hands, they will, if held in close contact for some time, re-unite by insensate, and cement like one branch of a tree ingrafted on another. To maintain them in this situation, several sorts of sutures have been invented, and formerly practised; but the number of them has of late been very much reduced. Those now chiefly described, are the interrupted, the glover's, the quilled, the twisted, and the dry sutures; but the interrupted and twisted, are almost the only useful ones; for the quilled suture is never preferable to the interrupted; the dry suture is ridiculous in terms, since it is only a piece of plaister applied in many different ways to re-unite the lips of a wound; and the glover's, or uninterrupted suture,

which is advised in superficial wounds, to prevent the deformity of a scar, does rather, by the frequency of the stitches, occasion it, and is therefore to be rejected in favour of a compress and sticking plaister; the only instance where it should be used, is in a wound of the intestine.

Wounds are not fit subjects for suture, when there is either a contusion, laceration, loss of substance, great inflammation, difficulty of bringing the lips into apposition, or some extraneous body insinuated into them; though sometimes a lacerated wound may be assisted with one or two stitches. It has formerly been forbidden to sew up wounds of the head; but this precaution is very little regarded by the moderns.

If we stitch up a wound that has none of these obstacles, we always employ the interrupted suture, passing the needle two, three, or four times, in proportion to the length of it, though there can seldom be more than three stitches required.

The method of doing it is this: the wound being emptied of the grumous blood, and your assistant having brought the lips of it together, that they may lie quite even; you carefully carry your needle from without, inwards to the bottom, and so on from within, outwards; using the caution of making the puncture far enough from the edge of the wound, which will not only facilitate the passing the ligature, but will also prevent it from entering through the skin and flesh. This distance may be three or four tenths of an inch: as many more stitches as you shall make, will be only repetitions of the same process. The threads being all passed, you begin tying them in the middle of the wound, though, if the lips are held carefully together all the while, as they should be, it will be of no great consequence which is done first. The most useful kind of knot in large wounds, is a single one first; over this, a little linen compress, on which is to be made another single knot; and then a slip-knot, which may be loosened upon any inflammation; but in small wounds, there is no danger from the double knot alone, without any compress to tie it upon; and this is most generally practised. If a violent inflammation should succeed, loosening the ligature only will not suffice; it must be cut through and drawn away, and the wound be treated afterwards without any suture. When the wound is small, the less it is disturbed by dressing, the better; but in large ones, there will sometimes be a considerable discharge, and if the threads be not cautiously carried through the bottom of it, abscesses will frequently ensue from the matter being pent up underneath, and not finding issue. If no accident happen, you must, after the lips are firmly agglutinated, take away the ligatures, and dress the orifices which they leave.

It must be remembered, that during the cure, the suture must be always assisted by the application of bandage, if possible, which is frequently of the greatest importance; and that sort of bandage with two heads, and a slit in the middle, which is by much the best, will in most cases be found practicable.

The twisted suture being principally employed in the hare-lip, we shall reserve its description for the section on that head.

Of the Suture of Tendons.

WOUNDS of the tendons are not only known to heal again, but even to admit of sewing up like those of the fleshy parts,

parts, though they do not re- unite in so short a time. When a tendon is partly divided, it is generally attended with an excessive pain, inflammation, &c. in consequence of the remaining fibres being stretched and forced by the action of muscle, which necessarily will contract more when some of its resistance is taken away. To obviate this mischief, it has been hitherto an indisputable maxim in surgery, to cut the tendon quite through, and immediately afterwards perform the future. But this practice is not advisable; for though the division of the tendon afford present ease, yet the mere flexion of the joint will have the same effect, if, for example, it be a wound of a flexor tendon: besides, in order to sew up the extremities of the tendon when divided, we are obliged to put the limb in such a situation, that they may be brought into contact, and even to sustain it in that posture to the finishing of the cure: if then, the posture will lay the tendon in this position, we can likewise keep it so without using the future, and are more sure of its not slipping away, which sometimes happens from any careless motion of the joint, when the stitches have almost worn through the lips of the wound; on which account, it is by all means advisable, in this case, to forbear the future, and only to favour the situation of the extremities of the tendon, by placing the limb properly.

But when the tendon is quite separated, and the ends are withdrawn from one another, having brought them together with your fingers, you may sew them with a straight triangular pointed needle, passing it from without inwards, and from within outwards in small tendons; about three tenths of an inch from their extremities, and in the *tendo Achillis* half an inch.

As the wound of the skin will be nearly transverse, it should not be raised to expose more of the tendon, but rather sewed up with it, which will conduce to the strength of the future. The knot of the ligature is to be made as in other wounds, and the dressings are to be the same: there is a sort of thin crooked needle that cuts on its concave and convex sides, which is very handy in the future of large tendons, and to be preferred to the straight one. During the cure, the dressings must be superficial and the parts kept steady with pasteboard and bandage: the small tendons reunite in three weeks, but the *tendo Achillis* requires six at least.

Of the GASTROGRAPHY.

THIS word signifies no more than sewing up any wound of the belly; yet in common acceptation, it implies that the wound of the belly is complicated with another of the intestine. Now the symptoms laid down for distinguishing when the intestine is wounded, do not with any certainty determine it to be wounded only in one place; which want of information makes it absurd to open the abdomen in order to come at it: if so, the operation of stitching the bowels can only take place where they fall out of the abdomen, and we can see where the wound is, or how many wounds there are: if it happens that the intestines fall out unwounded, the business of the surgeon is to return them immediately, without waiting for spirituous or emollient fomentations; and in case they puff up so as to prevent their reduction by the same orifice, you may with a knife or probe-scissors sufficiently dilate it for that purpose, or even prick them to let out the wind.

Upon the supposition of the intestine being wounded in

such a manner as to require the operation, (for in small punctures it is not necessary,) the method of doing it may be this: Taking a straight needle with a small thread, you lay hold of the bowel with your left hand, and sew up the wound by the glover's stitch, that is, by passing the needle through the lips of the wound, from within outwards all the way, so as to leave a length of thread at both ends, which are to hang out of the incision of the abdomen; then carefully making the interrupted future of the external wound, you pull the bowel by the small threads into contact with the peritonæum, in order to procure an adhesion, and tie them upon a small bolster of linen. In about six days, it is said the ligature of the intestine will be loose enough to be cut and drawn away, which must be done without great force; in the interim, the wound is to be treated with superficial dressings, and the patient to be kept very still and low.

Of the BUBONOCÆLE.

WHEN the intestine or omentum falls out of the abdomen into any part, the tumour in general is known by the name of *hernia*; which is farther specified either from the difference of situation, or the nature of its contents. When the intestine or omentum falls through the navel, it is called a *hernia umbilicalis*, or *exomphalos*; when through the rings of the abdominal muscles into the groin, *hernia inguinalis*; or if into the scrotum, *scrotalis*: these two last, though the first only is properly so called, are known by the name of bubonocœle. When they fall under the *ligamentum Falsopii*, through the same passage that the iliac vessels creep into the thigh, it is called *hernia femoralis*. The bubonocœle is also sometimes accompanied with a descent of the bladder: however, the case is very rare; but when it occurs, it is known by the patient's inability to urinate, till the hernia of the bladder is reduced within the pelvis. With regard to the contents characterizing the swelling, it is thus distinguished: if the intestine only is fallen, it becomes an *enterocœle*; if the omentum, (*epiploon*) *epiplocœle*; and if both, *entero-epiplocœle*. There is, besides these, another kind of hernia mentioned and described by the moderns, when the intestine or omentum is insinuated between the interstices of the muscles, in different parts of the belly: this hernia has derived its name from the place affected, and is called the *hernia ventralis*; and lastly, there have been a few instances, where the intestines or omentum have fallen thro' the great foramen of the ischium into the internal part of the thigh, between and under the two anterior heads of the triceps muscle.

All the kinds of hernias of the intestines and omentum, are owing to a preternatural dilatation of the particular orifices through which they pass, and not to a laceration of them.

The rupture of the groin, or scrotum, is the most common species of hernia, and in young children is very frequent; but it rarely happens in infancy, that any mischief arise from it. For the most part, the intestine returns of itself into the cavity of the abdomen, whenever the person lies down, at least a small degree of compression will make it. To secure the intestine when returned into its proper place, there are steel trusses now so artfully made, that by being accommodated exactly to the part, they perform the office of a bolster, without galling, or even sitting uneasily on the patient. These instruments are of so great service, that

S B † were

were people who are subject to ruptures always to wear them, very few would die of this distemper; since it often appears, upon inquiry, when we perform the operation for the bubonocoele, that the necessity of the operation is owing to the neglect of wearing a truss.

In the application of a truss to these kinds of swellings, a great deal of judgment is sometimes necessary, and for want of it, we daily see trusses put even on buboes, indurated testicles, hydrocles, &c.

If there is a rupture of the intestine only, it is easily, when returned into the abdomen, supported by an instrument; but if of the omentum, notwithstanding it may be returned, yet the reduction seldom brings relief, unless there is only a small quantity of it; for the omentum will lie uneasily in a lump at the bottom of the belly, and, upon removal of the instrument, drop down again immediately; upon which account, seeing the little danger and pain there is in this kind of hernia, nothing need be used but a bag, truss, to suspend the scrotum, and prevent possibly by that means the increase of the tumour. The difference of these tumours will be distinguished by the feel; that of the omentum feeling flaccid and rumpled, the other more even, flatulent, and springy.

Sometimes, in a rupture of both the intestine and omentum, the gut may be reduced, but the omentum will still remain in the scrotum; and when thus circumstanced, a steel truss must be used.

We have hitherto considered the rupture as moveable; but it happens frequently, that the intestine, after it has passed the rings of the muscles, is presently inflamed, which enlarging the tumour, prevents the return of it into the abdomen, and becoming every moment more and more strangulated, it soon tends to a mortification, unless we dilate the passages through which it is fallen, with some instrument, to make room for its return; which dilatation is the operation for the Bubonocoele.

It rarely happens that patients submit to this incision before the gut is mortified, and it is too late to do service; not but that there are instances of people surviving small gangrenes, and even perfectly recovering afterwards.

In mortifications of the bowels, when fallen out of the abdomen into the navel, it is not very uncommon for the whole gangrened intestine to separate from the sound one, so that the excrement must necessarily ever after be discharged at that orifice; there are likewise a few instances, where the rupture of the scrotum has mortified, and become the anus, the patient doing well in every other respect.

Before the performance of the operation for the bubonocoele, which is only to be done in the extremity of danger, the milder methods are to be tried; these are, such as will conduce to soothe the inflammation.

Perhaps except the pleurisy, no disorder is more immediately relieved by plentiful bleeding than this: Clysters repeated, one after another, three or four times, if the first or second are either retained too long, or immediately returned, prove very efficacious: these are serviceable, not only as they empty the great intestines of their excrements and flatulencies, which last are very dangerous, but they likewise prove a comfortable fomentation, by passing thro' the colon all around the abdomen. The scrotum and groin must, during the stay of the clyster, be bathed with warm sops wrung out of a fomentation; and after the part has been well fomented, you must attempt to reduce the rup-

ture: for this purpose, let your patient be laid on his back, so that his buttocks may be considerably above his head; the bowels will then retire towards the diaphragm, and give way to those which are to be pushed in. If, after endeavouring two or three minutes, you do not find success, you may still repeat the trial.

If, notwithstanding these means, the patient continues in very great torture, though not so bad as to threaten an immediate mortification, we must apply some sort of poultice to the scrotum; such as equal parts of oil and vinegar made into a proper consilience with oat-meal: after some few hours, the fomentation is to be repeated, and the other directions put in practice.

After all, should the pain and tenderness of the part continue, and hiccoughs and vomitings of the excrements succeed, the operation must take place; for if you wait until a languid pulse, cold sweats, subsiding of the tumour, and emphysematous feel come on, it will be most likely too late, as they are pretty sure symptoms of a mortification.

To conceive rightly of the occurrences in this operation, it must be remembered, that in every species of rupture, a portion of the *peritoneum* generally falls down with whatever makes the *hernia*; which, from the circumstance of containing immediately the contents of the tumour, is called the *sac* of the *hernia*. Now, the portion of the *peritoneum*, which usually yields to the impulsion of the descending *viscera*, is that which corresponds with the inmost opening of the abdominal muscles, just where the *membrana cellularis peritonæi* begins to form the *tunica vaginalis* of the spermatic cord; so that the *sac* with the *viscera* insinuates themselves into the *tunica vaginalis* of the spermatic cord, and lie upon the *tunica vaginalis* of the testicle: nevertheless, upon examination, the contents of the *hernia* are sometimes in contact with the testicle itself; that is to say, within the *tunica vaginalis* of the testicle. For some months during gestation, the *testes* of the *fœtus* remain in the *abdomen*; and when they descend into the *tunica vaginalis*, there is an immediate communication betwixt the cavity of the *abdomen*, and the cavity of the *tunica vaginalis*, which, in process of time, becomes obliterated by the coalition of the *tunicæ* with the cord; but if it happen, before the coagulation be effected, that the intestine or the *omentum* fall into the *scrotum*, they will necessarily remain in contact with the *testes*.

From this description of the descent of the *viscera*, it is evident that the *herniary sac* is contained within the *tunica vaginalis*, and ought to give the idea of one bag inclosing another: but in the operation, this distinction of coats does not always appear; for the *herniary sac* sometimes adheres so firmly to the *tunica vaginalis*, that together they make one thick coat: this adhesion may possibly result from the present inflammation of the parts, which has rendered the operation necessary.

The best way of laying your patient will be on a table about three feet four inches high, letting his legs hang down; then properly securing him, you begin your incision above the rings of the muscles, beyond the extremity of the tumour, and bring it down about half the length of the *scrotum*, through the *membrana adiposa*, which will require very little trouble to separate from the *tunica vaginalis*, and consequently will expose the rupture for the farther process of the operation. If a large vessel is opened by the incision, it must be taken up before you proceed further.

When

When the *tunica vaginalis* is laid bare, you must cut carefully through it and the *peritoneum*, in order to avoid ripping the intestines.

The *peritoneum* being cut through, we arrive to its contents, the nature of which will determine the next process: or if it is intestine only, it must directly be reduced, but if there is any mortified *omentum*, it must be cut off; in order to which it is advised to make a ligature above the part wounded, to prevent an hæmorrhage; but it is quite needless, and in some measure pernicious, as it puckers up the intestine, and disorders its situation, if made close to it.

When the *omentum* is removed, we next dilate the wound; to do which with safety, an infinite number of instruments have been invented: but there is none we can use in this case with so good management as a knife; and the finger in this operation is often a much better defence against pricking the bowels, than a director. The knife must be a little crooked and blunt at its extremity, like the end of a probe. Some surgeons perhaps may not be steady enough to cut dexterously with a knife, and may therefore perform the incision with probe-passars carefully introducing one blade between the intestine and circumference of the rings, and dilating upwards, and a little obliquely outwards. When the finger and knife only are employed, the manner of doing the operation will be by pressing the gut down with the fore-finger, and carrying the knife between it and the muscles, so as to dilate upwards about an inch, which will be a wound generally large enough: but if, upon examination, it shall appear that the intestine is strangulated within the *abdomen*, which may possibly happen from a contraction of the *peritoneum* near the entrance into the *jac*; in that case, the incision must be continued through the length of the contracted channel, or the consequence will be fatal, notwithstanding the intestine be restored into the *scrotum*: on this account the operator should pass his finger up the *jac* into the *abdomen*, after the reduction of the gut, in order to discover whether it be safely returned into its proper place.

The opening being made, the intestine is gradually to be pushed into the *abdomen*, and the wound to be stitched up; for this purpose, some advise the quilled, and others the interrupted suture, to be passed through the skin and muscles; but as there is not so much danger of the bowels falling out when a dressing and bandage are applied, and the patient all the while kept upon his back, but that it may be prevented by one or two slight stitches through the skin only, it is by all means advisable to follow this method, since the stricture of a ligature in these tendinous parts may be dangerous.

Hitherto, in the description of the *bubonocèle*, we have supposed the contents to be loose, or separate in the *jac*: but it happens sometimes in an operation, that we find not only an adhesion of the outside of the *peritoneum* to the *tunica vaginalis*, and spermatic vessel, but like wise of some part of the intestines to its internal surface; and in this case there is so much confusion, that the operator is often obliged to extirpate the testicle, in order to dissect away and disentangle the gut; though if it can be done without castration, it ought: however, this accident happens rarely, except in those ruptures that have been a long time in the *scrotum* without returning: in which case the difficulty and hazard of the operation are so great, that, unless urged by the symptoms of an inflamed intestine, it should not be undertaken.

The dressing of the wound first of all may be with dry lint, and afterwards as directed under the head of wounds.

The operation of the *bubonocèle* in women so nearly resembles that performed on men, that it requires no particular description: only in them the rupture is formed by the intestine or *omentum* falling down through the passage of the *ligamentum rotundum* into the groin, or one of the *labia pudendi*; where causing the same symptoms, as when obstructed in the *scrotum*, it is to be returned by the dilatation of that passage.

Of the EPIFLOCELE.

THERE have been a few instances where so great a quantity of the *omentum* has fallen into the *scrotum*, that, by drawing the stomach and bowels downwards, it has excited vomitings, inflammation, and the same train of symptoms as happen in a *bubonocèle*; in which case, the operation of opening of the *scrotum* is necessary: the incision must be made in the manner of that for the rupture of the intestine, and the same rules observed with regard to the *omentum* that are laid down in the last section. It is necessary also, the rings or the muscles should be dilated; or otherwise, though you have taken away some of the mortified part of the *omentum*, the rest that is out of its place, and strangled in the perforation, will gangrene also. The wound is to be treated in the same manner as that after the operation of the *bubonocèle*.

Of the HERNIA FEMORALIS.

THIS species of rupture is the same in both sexes, and formed by the falling of the *omentum* or intestine, or both of them, into the inside of the thigh, through the arch made by the *os pubis* and *ligamentum Fallopii*, where the iliac vessels and tendons of the *psoas* and *iliacus internus* muscles pass from the *abdomen*. It is very necessary surgeons should be aware of the frequency of this disorder, which creates the same symptoms as other ruptures, and must first of all be treated by the same methods: the manner of operating in the reduction is here too so exactly the same, with the difference of dilating the ligament instead of the rings of the muscles, that it would be a mere repetition of the operation for the *bubonocèle* to give any description of it: only it may be observed, that the spermatic cord, as it enters into the *abdomen*, lies nearly transverse to the incision, and close in contact with the ligament; so that unless you make the dilatation obliquely outwards, instead of perpendicularly upwards, you will probably divide those vessels.

Of the EXOMPHALOS.

THIS rupture is owing to a protrusion of the intestine, or *omentum*, or both of them, at the navel, and rarely happens to be the subject of an operation: for though the case is common, yet most of them are gradually formed from very small beginnings; and if they do not return into the *abdomen* upon lying down, in all probability they adhere without any great inconvenience to the patient, till some time or other an inflammation falls upon the intestines, which soon brings on a mortification, and death: unless, by great chance, the mortified part separates from the sound one, leaving its extremity to perform the office of an *anus*: in this emergency, however, it is advisable to attempt the reduction, if called in at the beginning, though the universal adhesion of the *jac* and its contents are a great obstacle to the success: the

the instance in which it is most likely to answer, is, when the rupture is owing to any strain, or sudden jerk, and is attended with those disorders which follow upon the strangulation of a gut.

In this case, having tried all other means in vain, the operation is absolutely necessary; which may be thus performed: Make the incision somewhat above the tumour, on the left side of the navel, through the *membrana adiposa*; and then emptying the sac of its water, or mortified omentum, dilate the ring with the same crooked knife, conducted on your finger, as in the operation for the bubonocoele; after this, return the intestines and omentum into the abdomen, and dress the wound without making any ligature but of the skin only.

Of the HERNIA VENTRALIS.

THE *hernia ventralis*, which sometimes appears between the recti muscles, is very large; but that tumour which requires the operation is seldom bigger than a walnut, and is a disease not so common as to have been observed by many; but there are cases enough known, to put a surgeon upon inquiry after it. When the patient is suddenly taken with all the symptoms of a rupture, without any appearance of one in the navel, scrotum, or thigh, the manner of dilating it will be the same as that above directed in the other hernias: after the operation in this and all hernias where the intestines have been reduced, it will be convenient to wear a truss, since the cicatrix is not always firm enough in any of them to prevent a relapse.

EXPLANATION of Fig. 2. Plate CLVII.

A, The round-edged knife, of a convenient size for almost all operations where a knife is used: the make of it will be better understood by the figure than any other description; only it may be remarked, that the handle is made of a light wood, as indeed the handles of all instruments should be, that the resistance to the blades may be better felt by the surgeon.

B, A pair of probe-scissors, which require nothing very particular in their form, but that the lower blade should be made as small as possible, so that it is strong, and has a good edge; because, being chiefly used in fistulas *in ano*, the introduction of a thick blade into the sinus, which is generally narrow, would be very painful to the patient.

C, The crooked knife with the point blunted, used in the operation of the bubonocoele.

Of the HYDROCELE.

THE *hydrocele*, called also *hernia aquosa*, *hydrops scroti*, and *hydrops testis*, is a watery tumour of the scrotum; which, notwithstanding the multiplicity of distinctions used by writers, is but of two kinds; the one when the water is contained in the *tunica vaginalis*, and the other when in the *membrana cellularis scroti*. This last is almost always complicated with an anasarca; which species of dropsy is an extravasation of water lodged in the cells of the *membrana adiposa*; and when thus circumstanced, will not be difficult to be distinguished; besides that it is sufficiently characterized by the shining and softness of the skin, which gives way to the least impression, and remains pitted for some time. The penis is likewise sometimes enormously enlarged, by the insinuation of the fluids into the *membra-*

na cellularis; all which symptoms are absolutely wanting in the dropsy of the *tunica vaginalis*.

In the dropsy of the *membrana cellularis scroti*, the puncture with the trocar is recommended by some, and little orifices made here and there with the point of a lancet by others; or a small skene of silk passed by a needle through the skin, and out again at the distance of two or three inches, to be kept in the manner of a seton, till the waters are quite drained: But the two first methods avail very little, as they open but few cells; and the last cannot be so efficacious in that respect as incisions, and will be much more apt to become troublesome, and even to gangrene.

Indeed it is not often proper to perform any operation at all upon this part, since the *membrana cellularis scroti*, being a continuation of the *membrana adiposa*, scarifications made through the skin in the small of the legs will effectually empty the scrotum: and this place ought rather to be pitched upon than the other, as being more likely to answer the purpose by reason of its dependency: however, it sometimes happens, that the waters fall in so great quantities into the scrotum, as, by distending it, to occasion great pain, and threaten a mortification: the prepuce of the penis also becomes very often excessively dilated, and so twisted, that the patient cannot void his urine. In these two instances, an incision of three inches long should be made on each side of the scrotum, quite through the skin into the cells containing the water, and two or three of half an inch long, in any part of the penis, with a lancet or knife; all which may be done with great safety, and sometimes with the success of carrying off the disease of the whole body.

The dropsy of the *tunica vaginalis* is owing to a preternatural discharge of that which is continually separating in a small quantity, on the internal surface of the tunica for the moistening or lubricating the testicle, and which collecting too fast accumulates and forms in time a swelling of great magnitude: this is what we take to be the other species of hydrocele, and the only one besides.

The hydrocele of the *tunica vaginalis* is very easily to be distinguished from the hydrocele of the *membrana cellularis*, by the preceding description of that species of dropsy: We shall now explain how it differs from the other tumours of the scrotum, *viz* the *bubonocoele*, *epiplocele*, and enlarged testicle. In the first place, it is seldom or never attended with pain in the beginning, and is very rarely to be imputed to any accident, as the hernia's of the omentum and intestine are. From the time it first makes its appearance, it very seldom is known to appear or diminish, but generally continues to increase, though in some much faster than in others; in one person growing to a very painful distension in a few months, whilst in another it shall not be troublesome in many years; nay, shall cease to swell at a certain period, and ever after continue in that state without any notable disadvantage; though this last case very rarely happens. In proportion as it enlarges, it becomes more tense, and then is said to be transparent: indeed the transparency is made the chief criterion of the distemper, it being constantly advised to hold a candle on one side of the scrotum, which it is said will shine through the other, if there be water. But this experiment does not always answer, because sometimes the *tunica vaginalis* is very much thickened, and sometimes the water itself is not transparent: so that to judge positively if there be a fluid, we must be guided by feeling a fluctuation: and

and though we do not perhaps evidently perceive it, yet we may be persuaded there is a fluid of some kind, if we are once assured that the distention of the *tunica vaginalis* makes the tumour; which is to be distinguished in the following manner.

If the intestine, or omentum, form the swelling, they will be soft and pliable, (unless inflamed;) uneven in their surface, particularly the omentum; and both of them extend themselves up from the scrotum quite into the very abdomen: whereas, in the hydrocele, the tumour is tense and smooth, and ceases before or at its arrival to the rings of the abdominal vessels; because the upper extremity of the *tunica vaginalis* terminates at some distance from the surface of the belly.

When the testicle is increased in its size, the tumour is rounder; and if not attended with an enlargement of the spermatic vessels, the cord may be easily distinguished between the swelling and abdomen; but without this rule of distinction, either the pain, or the very great hardness, will discover it to be a disease of the testicle.

As to the cure of this distemper by external applications, or internal means, little is to be expected; on which account, it is generally advisable to wait with patience until the tumour becomes troublesome, and then to tap it with a lancet or trocar. In opening with a lancet, it may possibly happen, that the orifice of the skin shall slip away from that of the tunick, and prevent the egress of the water: to obviate which inconvenience, you may introduce a probe, and by that means secure the exact situation of the wound; but if the coats are very much thickened, it will be advisable to use the trocar, rather than the lancet. It is spoken of as an easy thing, to hold the testicle with the left hand, while we make the puncture with the right; but when the *tunica vaginalis* is very tense, it cannot well be distinguished: however, there is no danger of wounding it, if you make the puncture in the inferior part of the scrotum. During the evacuation, the scrotum must be regularly pressed; and after the operation, a little piece of dry lint and sticking plaster are sufficient.

This method of tapping is called the palliative cure; not but that it does now and then prove an absolute one. To prevent the relapse of this disease, surgeons prescribe the making a large wound, either by incision or caustic, that upon healing it afterwards, the firmness and contraction of the cicatrix may bind up the relaxed lymphatic vessels, and obstruct the further preternatural effusion of their contents: but this practice is generally attended with so much trouble, that, notwithstanding its success in the end, most surgeons prefer the palliative.

Of Castration.

This is one of the most melancholy operations in the practice of surgery, since it seldom takes place but in disorders into which the patient is very apt to relapse, viz. those of a scirrhus, or cancer: for under most of the symptoms described as rendering it necessary, it is absolutely improper; such as a hydrocele, abscess of the testes, an increasing mortification, or what is sometimes understood by a farctocoele; of which last it may not be amiss to say a word. In the utmost latitude of the meaning of this term, it is received as a fleshy swelling of the testicle itself, called likewise *hernia carnosae*; or in some enlargements, such as in a clap, more frequently *hernia humoralis*; but generally speaking, is considered as a fleshy excrescence formed on the body of the testis, which

becoming exceedingly hard and tumefied, for the most part is supposed to demand extirpation, either by cutting or burning away the induration, or amputating the testicle. But this maxim too precipitately received, has very much misguided the practitioners of surgery.

It sometimes happens that the epididymis is tumefied, independent of the testicle; and feeling like a large adventitious excrescence, answers very well to the idea most surgeons form of a *farctocoele*: but not being aware of the different nature and texture of the epididymis, they have frequently confounded its disorders with those of the testicle itself, and equally recommended extirpation in the induration of one or the other. But all indurations of the glandular part of the testicle not tending to inflammation and abscess, generally, if not always, lead on to scirrhus and cancers; whereas those of the epididymis seldom or never do. It is true, in spite of internal or external means, these last often retain their hardness, and sometimes suppurate, but however without much danger in either case.

Before castration, it is laid down as a rule to inquire whether the patient has any pain in his back, and in that case to reject the operation, upon the reasonable presumption of the spermatic vessels being likewise diseased: but we are not to be too hasty in this determination; for the mere weight of the tumour stretching the cord, will sometimes create this complaint. To learn the cause then of this pain in the back, when the spermatic cord is not thickened, let your patient be kept in bed, and suspend his scrotum in a bag-truss, which will relieve him, if disordered by the weight only; but if the spermatic cord is thickened or indurated, which disease, when attended with a dilatation of the vessels of the scrotum, is known by the Greek appellations *circocoele* and *varicocoele*, the case is desperate, and not to be undertaken.

But supposing no obstacle in the way to the operation, the method of doing it may be this: Lay your patient on a square table of about three feet four inches high, letting his legs hang down, which, as well as the rest of his body, must be held firm by the assistants. Then with a knife begin your wound above the rings of the abdominal muscles, that you may have room afterwards to tie the vessels, since for want of this caution operators will necessarily be embarrassed in making the ligature: then carrying it through the *membrana adiposa*, it must be continued downward, the length of it being in proportion to the size of the testicle. If it is very small, it may be dissected away without taking any part of the scrotum. If the testicle, for instance, weighs twenty ounces; having made one incision about five inches long, a little circularly, begin a second in the same point as the first, bringing it with an opposite sweep to meet the other in the inferior part, in such a manner as to cut out the shape of an oval whose smallest diameter shall be two inches: after this, dissect away the body of the tumour, with the piece of skin on it, from the scrotum; first taking up some of the blood-vessels, if the hemorrhage is dangerous. Then pass a ligature round the cord, pretty near the abdomen, and if you have space between the ligature and testicle, a second about half an inch lower, to make the stoppage of blood still more secure. The ligatures may be tied with what is called the *surgeon's knot*, where the thread is passed through the ring twice. This done, cut off the testicle a little underneath the second ligature, and pass a needle from the skin at the lower part of the wound through the skin at the upper part, in such a manner as to envelope in

some degree the sound testicle, which will greatly facilitate and quicken the cure; or if one flitch will not answer the purpose, you may repeat it in such part of the wound where the skin on each side lies most loose.

In large tumours, it is advisable to cut away great part of the skin; for besides that the hæmorrhage will be much less in this case, and the operation greatly shortened, the skin by the great distension having been rendered very thin, will great part of it, if not taken away, sphacelate, and the rest be more prone to degenerate into a cancerous ulcer.

Of the PHYMOSIS.

THE *phymosis* signifies no more than such a straitness of the prepuce, that the glans cannot be denuded; which if it becomes troublesome, so as to prevent the egress of the urine, or conceal under it chancres, or foul ulcers, quite out of the reach of application, is to be cut open. It sometimes happens, that children are born imperforate; in which case, a small puncture, dressed afterwards with a tent, effects a cure. But this operation is chiefly practised in venereal cases, in order to expose chancres either on the glans or within the prepuce itself: and here, if the prepuce is not very callous and thick, a mere incision will answer; which may be made either with the scissors, or by slipping a knife between the skin and glans to the very extremity, and cutting it up: the last method is more easy than that of the scissors; but it is safer to make the wound on the side of the prepuce than upon the upper part, for sometimes the great vessels on the *dorsum penis* afford a terrible hæmorrhage; though the prepuce remains better shaped after an incision made in the upper part, and therefore is to be preferred by those who undertake how to take up the vessels. In children it sometimes happens that the prepuce becomes very much contracted; and in that case, it is accidentally subject to slight inflammations, which bring on some symptoms of the stone; but the disorder is always removed by the cure of the phymosis.

If the prepuce be very large and indurated, the opening alone will not suffice; and it is more advisable to take a way the callosity by circumcision, which must be performed with a knife; and if the artery bleed much, it must be taken up with a small needle and ligature.

Of the PARAPHIMOSIS.

THE paraphimosis is a disease of the penis, where the prepuce is fallen back from the glans, and cannot be brought forwards to cover it. There are many whose penis is naturally thus formed, but without any inconvenience; so that since the time of the Romans, (some of whom thought it indecent to have the glans bare) it has not been usual to perform any operation upon that account; but we read the several processes of it described very particularly by Celsus, who does not speak of it as an uncommon thing. Most of the instances of this distemper are owing to a venereal cause; but there are some where the prepuce is naturally very tight, which take their rise from a sudden retraction of it, and immediate enlargement of the glans preventing its return. Sometimes it happens that the surgeon succeeds in the reduction immediately, by compressing the extremity of the penis, at the time he is endeavouring to advance the prepuce; if he does not, let him keep it suspended, and attempt again, after having fomented, and used some emollient applications: but if, from the contraction below the

corona glandis, there is so great a stricture as to threaten a gangrene, or even, if the penis is much enlarged by water in the *membrana reticularis*, forming tumours called *crySTALLINE*, three or four small incisions must be made with the point of a lancet, into the stricture and *crySTALLINE*, according to the direction of the penis; which in the first case will set free the obstruction, and in the other evacuate the water: the manner of dressing afterwards must be with fomentations, digestives, and the *theriaca Londinensis* over the pledgits.

Of the PARACENTESIS.

THIS operation is an opening made into the abdomen, in order to empty any quantity of extravasated water, collected in that species of dropsy called the *ascites*; but as there is much more difficulty in learning when to perform than how to perform it, and indeed in some instances requires the nicest judgment, we shall endeavour to specify the distinctions which render the undertaking more or less proper.

There are but two kinds of dropsy: the *anasarca*, called also *leucophlegmacy*, when the extravasated water swims in the cells of the *membrana adiposa*; and the *ascites*, when the water possesses the cavity of the abdomen. In the first kind, the water is clear and limpid; but in the second, a little grosser, very often gelatinous and corrupted, and sometimes even mixed with fleshy concretions.

The operation of tapping is seldom the cure of the distemper: but dropsies, which are the consequence of a mere impoverishment of the blood, are less likely to return than those which are owing to any previous disorder of the liver; and it is not uncommon for dropsies that follow agues, hæmorrhages, and diarrhœis, to do well; whereas in such as are complicated with a scirrhus liver, there is hardly an example of a cure.

The water floating in the belly, is, by its fluctuation, to determine whether the operation be advisable: for, if, by laying one hand on any part of the abdomen, you cannot feel an undulation from striking on an opposite part with the other, it is to be presumed there will be some obstacle to the evacuation. It sometimes happens, that a great quantity, or almost all the water, is contained in little bladders, adhering to the liver and the surface of the *peritonæum*, known by the name of *hydatids*; and the rest of it in different sized ones, from the degree of a *hydatid*, to the size of a globe holding half a pint or a pint of water. This is called the encysted dropsy, and from the smallness of its cysts makes the operation useless; but is not difficult to be distinguished, because there is not a fluctuation of the water, unless it is complicated with an extravasation.

When the fluctuation is hardly perceptible, (except the teguments of the abdomen are very much thickened by an *anasarca*), in all probability the fluid is gelatinous.

There is another kind of dropsy, which for the most part forbids the operation, and is peculiar to women, being seated in the body of one or both ovaries. There is no example of this species but what may be known by the hardness and irregularity of the tumour of the abdomen, which is nearly uniform in the other cases.

When the ovary is dropical, the water is generally deposited in a great number of cells formed in the body of it; which circumstance makes the fluctuation insensible, and the perforation useless: though sometimes there are only one or

two cells; in which case, if the ovary is greatly magnified, the undulation will be readily felt, and the operation be ad-
feasible.

When the *ascites* and *anasarca* are complicated, it is seldom proper to perform the operation, since the water may be much more effectually evacuated by scarifications in the legs than by tapping.

Upon the supposition nothing forbids the extraction of the water, the manner of operating is this: Having placed the patient in a chair of a convenient height, let him join his hands so as to press upon his stomach; then dipping the trocar in oil, you stab it suddenly through the teguments, and, withdrawing the perforator, leave the waters to empty by the canula: the *abdomen* being, when filled, in the circumstance of a bladder distended with a fluid, would make it indifferent where to wound; but the apprehension of hurting the liver, if it be much enlarged, has induced operators rather to chuse the left side, and generally in that part which is about three inches obliquely below the navel: if the navel protrudes, you may make a small puncture with a lancet through the skin, and the waters will be readily voided by that orifice, without any danger of a *hernia* succeeding; but it should be carefully attended to, whether the protuberance is formed by the water or an *exomphalos*; in which latter case, the intestine would be wounded, and not without the greatest danger. The surgeon neither in opening with the lancet, nor perforating with the trocar, need fear injuring the intestines, unless there is but little water in the *abdomen*, since they are too much confined by the mesentery to come within reach of danger from these instruments, but it sometimes happens, that when the water is almost all emptied, it is suddenly stopped by the intestine or *omentum* pressing against the end of the canula; in which case you may push them away with a probe: during the evacuation, your assistants must keep pressing on each side of the *abdomen*, with a force equal to that of the waters before contained there; for by neglecting this rule, the patient will be apt to fall into faintings, from the weight on the great vessels of the *abdomen* being taken off, and the sinking of the diaphragm succeeding; in consequence of which, more blood flowing into the inferior vessels than usual, leaves the superior ones of a sudden too empty, and thus interrupts the regular progress of the circulation. To obviate this inconvenience, the compression must not only be made with the hands during the operation, but be afterwards continued, by swathing the *abdomen* with a roller of flannel, about eight yards long, and five inches broad, beginning at the bottom of the belly, so that the intestines may be borne up against the diaphragm: you may change the roller every day till the third or fourth day, by which time the several parts will have acquired their due tone. For the dressing a piece of dry lint and plaster suffice; but between the skin and roller it may be proper to lay a double flannel a foot square, dipt in brandy or spirits of wine.

This operation, though it does not often absolutely cure, yet it sometimes preserves life a great many years, and even a pleasant one, especially if the waters have been long collecting.

EXPLANATION of Fig. 3. Plate CLVII.

A, A trocar of the most convenient size for emptying the *abdomen* when the water is not gelatinous. It is here re-

presented with the perforator in the canula, just as it is placed when we perform the operation.

B, The canula of a large trocar, recommended in cases where the water is gelatinous.

C, The perforator of the large trocar.

The handle of the trocar is generally made of wood, the canula of silver, and the perforator of steel. Great care should be taken by the makers of this instrument, that the perforator should exactly fill up the cavity of the canula; for unless the extremity of the canula lies quite close and smooth on the perforator, the introduction of it into the *abdomen* will be very painful. To make it slip in more easily, the edge of the extremity of the canula should be thin and sharp; and that the canula should be of steel; for the silver one being of too soft a metal, becomes jagged or bruised at its extremity with very little use.

Of the FISTULA IN ANO.

THE *fistula in ano* is an abscess running upon or into the *intestinum rectum*.

The piles, which are little tumours formed about the verge of the *anus*, immediately within the *membrana interna* of the *rectum*, do sometimes suppurate, and become the fore-runners of a large abscess; also external injuries here, as in every other part of the body, may produce it; but from whatever cause the abscess arise, the manner of operating upon it will be according to the nature and direction of its cavity.

If the surgeon have the first management of the abscess, and there appear an external inflammation upon one side of the buttock only; after having waited for the proper maturity, let him with a knife make an incision the whole length of it; and in all probability, even though the bladder be affected, the largeness of the wound, and the proper application of doffs lightly pressed in, will prevent the putrefaction of the intestine, and make the cavity fill up like imposthumations of other parts.

If the *sinus* be continued to the other buttock, almost surrounding the intestine, the whole course of it must be dilated in like manner; since, in such spongy cavities, a generation of flesh cannot be procured but by large openings; whence also, if the skin is very thin, lying loose and flabby over the *sinus*, it is absolutely necessary to cut it quite away, or the patient will be apt to sink under the discharge, which, in the circumstance here described, is sometimes excessive. By this method, which cannot be too much recommended, it is amazing how happy the event is likely to be; whereas, from neglecting it, and trusting only to a narrow opening, if the discharge do not destroy the patient, at least the matter, by being confined, corrupts the gut, and insinuating itself about it, forms many other channels, which running in various directions often baffle an operator, and have been the cause of a fistula being to generally esteemed very difficult of cure.

Here we have considered the imposthumation as possessing a great part of the buttock; but it more frequently happens, that the matter points with a small extent of inflammation on the skin, and the direction of the *sinus* is even with the gut: in this case, having made a puncture, you may with a probe learn if it has penetrated into the intestine by passing your finger up it, and feeling the probe introduced through the wound into its cavity; though, for the most part, it may

be known by a discharge of matter from the *anus*. When this is the state of the fistula, there is no hesitation to be made; but immediately putting one blade of the scissars up the gut, and the other up the wound, snip the whole length of it. This process is as advisable when the intestine is not perforated, if the *sinus* is narrow, and runs upon or very near it; for if the abscess be tented, which is the only way of dressing it while the external orifice is small, it will almost certainly grow callous; so that the surest means of cure, will be opening the gut, that proper applications may be laid to the bottom of the wound. However, it should be well attended to, that some *sinuses* pretty near the intestine neither run into nor upon it; in which case, they must be opened, according to the course of their penetration. There are abundance of instances, where the intestine is so much ulcerated, as to give free issue to the matter of the abscess by the *anus*; but there are none where there is not, by the thinness and discolouration of the skin, or an induration to be perceived through the skin, some mark of its direction; which, if discovered, may be opened into with a lancet, and then it becomes the same case as if the matter had fairly pointed.

If the *sinuses* into and about the gut are not complicated with an induration, and you can follow their course; the mere opening with scissars, or a knife guided on a director, will sometimes suffice; but it is generally safer to cut the piece of flesh surrounded by these incisions quite away, and, when it is callous, absolutely necessary, or the callosities must be wasted afterwards by escharotick medicines, which is a tedious and cruel method of cure.

When the fistula is of a long standing, and we have choice of time for opening it, a dose of rhubarb the day before the operation will be very convenient, as it not only will empty the bowels, but also prove an alstringent for a while, and prevent the mischief of removing the dressings in order to go to stool.

It sometimes happens, that the orifices are so small, as not to admit the entrance of the scissars; in which case, sponge tents must be employed for their dilatation.

In performing these operations on the *anus*, no instruments are so handy as the knife and scissars; almost all the others which have been invented to facilitate the work are not only difficult to manage, but more painful to the patient: however, in those instances where the fistula is very narrow, and opens into the intestines, just within the verge of the *anus*, the syringotomy may be used with advantage; but where the opening into the gut is high, it cannot be employed without giving great pain.

The worst species of fistula is that communicating with the *urethra*, and sometimes (through the prostate gland) with the bladder itself. This generally takes its rise from a former gonorrhoea, and appears externally first in *perineo*, and afterwards increasing more towards the *anus*, and even sometimes into the groin, bursts out in various orifices, through the skin, which soon becomes callous and rotten; and the urine passing partly through these orifices, will often excite as much pain, and of the same kind, as a stone in the bladder.

This species of fistula taking its rise from strictures of the *urethra*, is only manageable by the bougie: for so long as the *urethra* is obstructed, the cure of the fistula will be imperfect; but if the canal be opened by this application, it is amazing what obdurate indurations and foul *sinuses* will

in consequence disappear; though there are some so called, and rotten, as to demand the knife and skilful dressing; notwithstanding the *urethra* should be dilated by the usual bougies.

Of the Puncture of the PÆRINEUM.

This operation is performed, when the bladder is under such a suppression of urine, as cannot be relieved by any gentler methods, nor, by reason of the obstruction in its neck, or the *urethra*, will admit of the introduction of a catheter. The manner of doing it, as described by most writers, is by pushing a common trocar from the place where the external wound in the old way of cutting is made, into the cavity of the bladder, and so procuring the issue of the water through the canula; but others, refining upon this practice, have ordered an incision to be carried on from the same part into the bladder, and then to infuse the canula: but both the methods are to be rejected, in favour of an opening a little above the *os pubis*: for besides that it is not easy to guide the instrument through the prostate gland into the bladder, the necessity of continuing it, in part already very much inflamed and thickened, seldom fails to do mischief, and even to produce a mortification.

There is another method still more easy both to the patient and the operator; which consists only in emptying the bladder with a common trocar, and stopping the canula with a little cork, which is afterwards to be taken out as often as the patient has occasion to urine. The canula is to be continued in the bladder, till such time as the person finds he can void his urine by the natural passage.

In this operation the *abdomen* ought to be perforated about two inches above the *os pubis*; and if the patient be fat, the trocar should penetrate two inches, otherwise an inch and a half will be sufficient.

Of the STONE.

STONY concretions are a disease incident to several parts of the body; but we shall treat only of those formed in the kidneys and bladder.

Small stones and gravel are frequently voided without pain; but sometimes they collect and become very large in the kidneys, in which case, a fit of the stone in that part is the cure, from the inflammation and pain occasioning convulsive twitches, which at last expel them. But in this disease the patient is very much relieved by several kinds of remedies, such as the mucilaginous, the saponaceous, &c. some of which lubricate, and others both lubricate and stimulate. The sand, in passing through the *ureters*, is very much forwarded by the force of the urine. The *ureters* being very narrow as they run over the *psos* muscle, and also at their entrance into the bladder, make the movement of the stone very painful and difficult in those parts; but there is seldom so much trouble after the first fit; for when once they have been dilated, they generally continue so. For the symptoms of a stone in the bladder, see MEDICINE, p. 122.

Of SEARCHING.

The patient being laid on a horizontal table, with his thighs elevated and a little extended, pass the sound with the concave part towards you, until it meets with some resistance in *perineo*, a little above the *anus*; then turning it without much force, push it gently on into the bladder; and

if it meets with an obstruction at the neck, raise its extremity upwards, by inclining the handle of it towards you; or if it don't then slip in, withdraw it a quarter of an inch, and introducing your fore-finger into the *rectum*, lift it up, and it will seldom fail to enter: there is some art in turning the found in the proper place of the *urethra*, which surgeons not versed in this operation cannot so well execute; therefore they may pass the instrument with the concave side always towards the *abdomen* of the patient, observing the same rule at the entrance into the bladder as in the other method. The cause of this obstacle, besides the *rugæ* of the *urethra*, and the resistance of the *verumontanum*, is sometimes a small projection of the orifice of the bladder, in the *urethra*, like that of the *os tincæ* in the *vagina*, which occasions the end of the found to slip a little beyond it.

Though, upon searching, we are assured of a stone in the bladder, we are not, without further inquiry, to operate immediately; since there are sometimes obstacles which forbid the operation, either absolutely, or only for a certain time; among these, that of greatest consequence, is the gravel or stone in the kidneys. The objections of less weight, and which frequently are removed, are a fit of the stone, a cough, a hectic, and being emaciated by long pain; excessive hot or cold weather are likewise hindrances: But in extremity of danger, these last considerations may be disregarded.

Difference of age makes an extreme difference of danger, infants and young people almost always recovering; but still the operation is advisable on those advanced in years, tho' it is not attended with near the same success. This operation is performed four several ways, all which we shall describe.

Of the LESSER APPARATUS, or Cutting on the GRIPE.

THE most ancient way of cutting for the stone, is that described by *Celsus*, and known by the name of *cutting on the gripe*; though, since the time of *Johannes de Romanis*, it is also called *cutting with the lesser apparatus*, to distinguish it from his new method, which, on account of the many instruments employed in it, is called *cutting with the greater apparatus*. The manner of doing the operation is this: You first introduce the fore finger and middle finger of the left hand, dipt in oil, up the *anus*, and pressing softly with your right hand above the *os pubis*, endeavour to bring the stone towards the neck of the bladder; then making an incision, on the left side of the *perineum*, above the *anus*, directly upon the stone, you turn it out through the wound, either with your fingers or a scoop.

This way of cutting was attended with many difficulties, for want of proper instruments to direct the incision, and extract the stone, when it lay beyond the reach of the fingers, which in a large bladder was frequently the case.

The wound of the bladder in this operation is made in the same place as is now practised in the lateral method; but it being impracticable on some subjects, and uncertain on all others, has made it universally exploded.

Of the GREATER APPARATUS, or the Old way.

THIS method of cutting, invented by *Johannes de Romanis*, has at different times, and with different people, varied considerably in some of its processes, and particularly with regard to the use of certain instruments. What we shall

describe, will be the manner in which it is now practised with all its improvements.

Having laid the patient on a square horizontal table, three feet four inches high, with a pillow under his head, let his legs and thighs be bent, and his heels made to approach his buttocks, byrning his hands to the bottom of his feet, with a couple of strong ligatures, about two yards long; and to secure him more effectually from struggling, pass a double ligature under one of his hams, and carry the four strings round his neck to the other ham; then passing the loop underneath it, make a knot by threading one of the single ends through the loop: After this, the thighs being widened from each other, and firmly supported by proper persons, you introduce the staff, having first dipt it in oil, which must be held by your assistant, a little leaning on the left side of the seam in *perineo*; and beginning the external wound just below the *scrotum*, (which must be held out of the way,) you continue it downwards, to within two fingers breadth of the *anus*; then leaving that direction, you slip the knife forwards in the groove, pretty far into the bulbous part of the *urethra*; or, as there is some danger of wounding the *rectum*, in the continuation of the incision, you may turn the knife with the back towards it, and make this part of the incision from within outwards. Should a very large vessel be cut, it will be advisable to tie it before you proceed any farther in the operation. When the wound is made, slide the gorget along the groove of the staff into the bladder; and to do it with more safety, when the beak of it is received in the groove, it will be proper to take the staff yourself in your hand: for if the assistant should, unwarily, either incline the handle of it too much towards you, or not resist enough to the force of the gorget, it is very apt to slip out of the groove, between the *rectum* and the bladder; which accident is not only inconvenient to the operator for the present, but is attended for the most part with very bad consequences. The gorget being passed, dilate the *urethra* and neck of the bladder with your fore-finger, and introduce the forceps into the bladder, keeping them shut till you touch the stone, when you must grasp it with a moderate force, and extract it by pulling downwards towards the *rectum*. Should you find a difficulty in laying hold of the stone, be careful to keep your forceps in such a position, that they may open upwards and downwards, (not laterally,) which will very much facilitate the embracing of the stone, in case it should happen to be thin and flat.

Of the HIGH OPERATION.

THIS method of cutting for the stone was first published in the year 1561, by *Pierre Franco*. About the year 1719, it was first done in *England* by Mr *Douglas*, and after him practised by others. The manner of performing it, with the improvements made since *Francis's* operation, is this:

The patient being laid on a square table, with his legs hanging over, and fastened to the sides of it by a ligature passing above the knee; his head and body lifted up a little by pillows, so as to relax the abdominal muscles; and his hands held steady by some assistants; insert through a catheter into the bladder as much barley-water as he can bear, which in a man is often about eight ounces, and sometimes, twelve. For the more easily doing this, an ox's *ureter* may be tied to the extremity of the syringe, and handle of the

catheter, which being pliable will prevent any painful motion of the instrument in the bladder.

The bladder being filled, an assistant, in order to prevent the reflux of the water, must grasp the *penis* the moment the catheter is withdrawn, holding it on one side, in such a manner as not to stretch the skin of the *abdomen*; then with a round edged knife make an incision about four inches long, between the *recti* and pyramidal muscles, through the *membrana adiposa*, as deep as the bladder, bringing its extremity almost down to the *penis*; after this, taking a crooked knife, continue the incision into the bladder, carrying it a little under the *os pubis*, and immediately upon the water's flowing out, introduce the fore-finger of your left hand, which will direct the forceps to the stone.

This method was at first received with great applause in London; but after some trial was rejected, for the following inconveniences.

It sometimes happens that the bladder, notwithstanding the injection, still continues so deep under the *os pubis*, that the *peritonæum* being necessarily wounded first, the intestines push out immediately at the orifice, and the urine afterwards empties into the *abdomen*; in which case, hardly any recovery. The injection itself is exceedingly painful; and however slowly the fluid be injected, it distends the bladder so much more suddenly than the urine from the kidneys does, and so much faster than it can well bear, that it not only is seldom dilated enough to make the operation absolutely secure, but is sometimes even burst, or at least its tone destroyed by the hasty dilatation. What adds to the danger here, is the possibility of meeting with a contracted indurated bladder; which is a circumstance sometimes attending on the stone, and indeed an exceedingly dangerous one in all the other methods; but would be frightful in this, by reason not only of the necessity of wounding the *peritonæum*, but of the difficulty of coming at the stone. If the stone be very small, it is hard to lay hold of it with the forceps, and in a fat man the fingers are not long enough for that purpose. If there are many little stones, it will scarce happen that more than one at a time can be extracted; and if the stone breaks, it not only is impracticable to take it all away in the operation, but also, from the supine posture of the patient, it will generally remain in the bladder; whereas, in the other methods, for the most part, it works itself out with the urine. But even supposing that the operation itself is prosperous, the consequences generally are very troublesome; for the urine issuing out at an orifice where there is no descent, spreads itself upon the *abdomen*, and makes very painful excoriations; though, what is still worse, it sometimes insinuates itself into the cells between the bladder and *abdominal* muscles, and, together with the inflammation excited by the operation, brings on a suppuration there, which is always difficult to manage, and frequently mortal.

Of the LATERAL OPERATION.

This method was invented by an ecclesiastic, who called himself *Frere Jaques*. He came to Paris in the year 1677, bringing with him an abundance of certificates of his dexterity in opening; and making his history known to the court, and magistrates of the city, he got an order to cut at the *Hotel Dieu*, and the *Charité*, where he performed this operation on about sixty persons. His success did not answer the promises he had made.

The principal defect in his manner of cutting was the want of a groove in his staff: which made it difficult to carry the knife exactly into the bladder; nor did he take any care of his patients after the operation; so that for want of proper dressings, some of the wounds proved fistulous, and other ill consequences ensued.

Chefelden, improving *Frere Jaques*'s method, made use of the following, which is now the practice of most operators.

The patient being laid on a table, with his hands and feet tied, and the staff passed as in the old way, let your assistant hold it a little slanting on one side, so that the direction of it may run exactly through the middle of the left *erector penis* and *accelerator urinae* muscles; then make your incision through the skin and fat, very large, beginning on one side of the seam in *perinae*, a little above the place wounded in the old way, and finishing a little below the anus, between it and the tuberosity of the ischium: this wound must be carried on deeper between the muscles, until the prostate be felt; when, searching for the staff, and fixing it properly, if it has slipped, you must turn the edge of the knife upwards, and cut the whole length of that gland from within outwards, at the same time pushing down the rectum with a finger or two of the left hand; by which precautions the gut will always escape wounding; after which, the operation finishes nearly in the same manner as with the greater apparatus.

If, upon introducing the forceps, you do not perceive the stone readily, you must lift up their handle, and feel almost perpendicularly for it; since for the most part, when it is hard to come at, it lies in one of the sinuses sometimes formed on each side of the neck of the bladder, which project forward in such a manner, that if the stone lie there, the forceps pass beyond it the moment they are through the wound; so that it would be impossible to lay hold of it, or even to feel it, if not aware of this circumstance.

When the stone breaks, it is much safer to take away the fragments with the forceps, than to leave them be discharged with the urine; and if the pieces are very small, like sand, a scoop is the best instrument; though some prefer the injecting barley-water into the bladder, which suddenly returning, brings away the broken particles of the stone.

As there are hardly any instances of more stones than one, when the stone taken away is rough; so when it is smooth and polished in any part of it, it is almost a certain sign of others behind; on which account, an operator should be careful, in that case, to examine not only with his fingers, but some convenient instrument, for the remaining ones; though indeed, in all cases, it may be proper to examine the bladder after the extraction of a stone; because it is possible there may be a second stone, notwithstanding the first be rough.

The great inconvenience of the lateral operation is the hæmorrhage which sometimes ensues in men; for in children the danger of it is not worth mentioning.

If in the operation any very large vessel of the external wound should be divided, it is advisable to tie it before the extraction of the stone; but the necessity of doing this, does not occur once in twenty times.

There is but one objection more of any consequence, which is the danger of wounding the rectum; and this is a very troublesome accident: But if the operator observes the rule laid down with regard to that article, it might always be avoided.

In this method the remarkable parts wounded by the knife are, the *musculus transversalis penis, levator ani, and prostate gland*: In the old way, the urethra only is wounded, about two inches on this side the prostate, and the instruments are forced through the rest of the passage, which is composed of the bulbous part of the urethra, the membranous part of the urethra, the neck of the bladder, and prostate gland. This channel is so very narrow, that, till it be torn to pieces, the management of the forceps is exceedingly difficult; and it happens frequently, that from the tender texture of the membranous parts, the forceps are so variously pushed through it between the *os pubis* and bladder; besides that in introducing the gorget upon the staff, it is apt to slip downwards between the rectum and bladder, both which inconveniences are avoided in the lateral operation. It is true, the wound made in the lateral method will not admit of the extraction of a large stone without laceration as well as in the old way: but in the one case, the laceration is small, and made after a preparation for it by an incision; and in the other, all the parts are torn without any previous opening, and which are so very tight, that the pain of the distension must necessarily be excessive. However, in both these operations, the surgeon must not grasp the stone with violence; and even in extracting, must, with both hands to the branches of his forceps, relit their shutting so tight, as the compression from the lips of such a narrow wound would otherwise make them. The extraction of very large stones is much more impracticable with the greater apparatus than by this method, because of the smallness of the angle of the bones in that part where the wound is made; so that indeed it is necessary in almost all extractions to pull the stone downward towards the rectum, which cannot be done without great violence to the membranous parts, and even the separation of one from another; whence follow abscesses and sloughs about the wound, which is a circumstance not known in the lateral operation. *Echinococcus* followed by suppuration and gangrene, sometimes spread themselves upon the scrotum; and in short, all the inconveniences and ill symptoms which attend upon the lateral operation, except the hæmorrhage, are in a more violent degree incident to the old way.

An incontinence of urine is not common after the lateral operation, and a fistula seldom or never the consequence of it.

The manner of treating the patient after the operation, is pretty nearly this: If it happens that the vessels of the prostate bleed, dry lint, or lint dipped in some styptic water, such as *aqua vitrioli*, must be applied to the part, and held there with a considerable degree of pressure for a few hours; or a silver canula of three or four inches long, covered with fine rag, may be introduced into the bladder, and left there two or three days, which seldom fails to stop the hæmorrhage. The patient may also take an opiate. If the wound does not bleed, a little dry lint, or a pledget of digestive, laid gently in it, is best. The place where the patient lies, should be moderately cool, as heat not only diffuses the vessels to bleed afresh, but generally makes him low and faint. If, soon after the operation, he complains of a sickness at the stomach, or even a pain in that part of the abdomen near the bladder, it is not always a sign of a dangerous inflammation, but frequently goes off in half an hour: to assist, however, in its removal, a fomentation put into an hog's bladder, and applied pretty warm to the part in pain, will be of great service: if the pain increases, af-

ter two or three hours, the consequence is much to be feared; and in this case, bleeding, and emollient clysters by way of fomentation to the bowels, are immediately necessary.

The first good symptom after the operation is the urine coming freely away, as we then know the lips of the bladder and prostate gland are not much inflamed. If the patient should become languid, and continue without any appetite, blisters prove beneficial; which may be applied with great safety, and little pain, as there is seldom or never any strangury. About the third or fourth day a stool must be procured by a clyster; for it seldom comes naturally the first time, and this method must be continued as every man's discretion shall guide him. As soon as the patient comes to an appetite, he should be indulged in eating light food; with this caution, that he do not eat too much at a time.

If, during the cure, the buttocks should be excoriated by the urine, let them be anointed with nutritum: the dressing from first to last is seldom any other than a soft digestive, or dry lint.

Of the Stone in the URETHRA.

If a small stone be lodged in the urethra near the glans, it may often be pushed out with the fingers, or picked away with some instrument; but if it stops in any other part of the channel, it may be cut upon without any inconvenience. The best way of doing it, is to pull the prepuce over the glans, as far as you can; and then making an incision the length of the stone, through the teguments, it may be turned out with a little hook or the point of a probe: The wound of the skin slipping back afterwards, to its proper situation, and from the orifice of the urethra, prevents the issue of the urine through that orifice, and very often heals in twenty-four hours. This is a much less painful method of extracting stones from the urethra, than by any instruments that have hitherto been devised.

Of the extraction of the Stone in WOMEN.

THE extraction of the stone in women, will easily be understood, since the whole operation consists in placing them in the same manner as men, and, without making any wound, introducing into the bladder a straight director, upon that a gorget, and afterwards the forceps to take hold of the stone; all which may be done without difficulty, by reason of the shortness of the urethra. If the stone proves very large, and in extracting draws the bladder forwards, it is advisable to make an incision through the neck of it, upon the stone; which not only will facilitate the extraction, but also be less dangerous than a laceration which will necessarily follow. The dressings are fomentations and emollient ointments, which should be applied two or three times a day, and the patient in other respects be treated like men who have undergone the operation for the stone.

EXPLANATION of Fig. 4. Plate CLVII.

A. A sound used in searching for the stone.

The size represented here is but a little too large for the youngest children, and may be used upon boys till they are thirteen or fourteen years of age; a larger should be employed between that age and adulthood, when one of about ten inches, in a right line from the handle to the extremity, is proper. This should be made of steel, and its extremity

B, A staff fit for the operation on boys from eight to fourteen years of age. The staff for a man must be of the size of the sound already described.

C, A staff something too big for the smallest children, but may be used upon boys from about four years of age to eight.

The staff has a groove on its convex side, which first serves as a direction where to cut, and afterwards receiving the beak of the gorget, guides it readily to the bladder. Care should be taken, in making the groove, that the edges of it be smoothed down, so that they cannot wound in passing through the urethra. The extremity should also be open; otherwise it will be sometimes difficult to withdraw the staff, when the gorget is introduced, and presses against the end of it.

These instruments are usually made with a greater bending than here represented; but this shape is more like to that of the urethra, and rather more advantageous for making the incision.

D, the yoke, an instrument to be worn by men with an incontinence of urine. It is made with iron, but for use must be covered with velvet. It moves upon a joint at one end, and is fastened at the other by catches at different distances placed on a spring. It must be accommodated to the size of the penis, and be taken off whenever the patient finds an inclination to make water. This instrument is exceedingly useful, because it always answers the purpose, and seldom galls the part after a few days wearing.

EXPLANATION OF Fig. 5. Plate CLVII.

A, A small catheter made of silver. This instrument is hollow, and serves to draw off the urine when under a suppression. It is also used in the high operation to fill the bladder with water. Near its extremity, are two orifices, through which the water passes into its cavity. Care should be taken that the edges of these orifices are quite smooth.

B, The knife used in cutting for the stone: it is the same already described; but it is not improper to repeat the figure with the alteration of a quantity of tow twisted round it, which makes it easier to hold, when we perform the lateral operation, and turn the edge upwards to wound the prostate gland.

C, A female catheter, differing from the male catheter, it being almost straight; and something larger.

D, A silver-wire to pass into either catheter, for the removing any grumous blood or matter that clogs them up.

EXPLANATION OF Fig. 6. Plate CLVII.

A, The gorget used upon men in the lateral operation.

B, The gorget used upon children under five years of age in the lateral operation.

A gorget between the sizes of these two will be fit for boys from five years of age to fifteen or sixteen.

These instruments are hollow for the passage of the forceps into the bladder; and their handles lie slanting, that they may the more readily be carried through the wound of the prostate, which is made obliquely on the left side of it. The beak at the extremity of the gorget must be smaller than the groove of the staff which is cut upon, because it is to be received in the groove. Care should be taken, that the edges of the gorget near the beak are not sharp, least, instead of dilating the wound, as it ought, it should only cut

on each side when introduced; in which case, it would be difficult to carry the forceps into the bladder.

C, A gorget, with its handle exactly in the middle; this shaped instrument is used in the old way. All the gorgets should be made of steel.

EXPLANATION OF Fig. 7. Plate CLVIII.

A, The forceps for extracting the stone. These are represented a little open, that the teeth may be better seen within-side.

This instrument must be of different sizes for different ages and stones, from the length of four inches to one of near a foot long; but the forceps of about eight inches long will be found most generally useful. The number necessary to be furnished with, will be four or five.

Great care should be taken by the makers of this instrument, that it move easily upon the rivet; that the extremity of the chops do not meet when they are shut; and particularly that the teeth be not too large, lest, in entering deep into the stone, they should break it. It is of consequence also that the teeth do not reach farther towards the joint than here represented, because a small stone, when received into that part, being held fast there, would dilate the forceps excessively, and make the extraction difficult; on which account, the inside of the blades near the joint should be smooth, that the stone may slip towards the teeth.

B, A director made of steel, used for the direction of the gorget, in the extraction of the stone from women.

C, A scoop to take away the stone when it is broken into small pieces like sand. This instrument is made of steel.

Of the EMPYEMA.

THE operation for the empyema generally implies an artificial opening made into the cavity of the thorax, by which we evacuate any fluid that lies there extravasated, and is become dangerous by its weight and quantity. The fluids described as necessary to be voided by this operation, are blood, matter, and water.

When blood is the fluid, supposed to require evacuation by this method, it is always extravasated through some wound of the vessels of the lungs or thorax, and being discharged in great quantities on the diaphragm, is said to oppress respiration, till let out by some convenient opening made in the most depending part of that cavity, which is the only kind of perforation into the thorax distinguished by the name of the operation for the *empyema*: But though this opening is universally recommended in the case here stated, yet we meet with few or no examples where it has been practised for a mere extravasation of blood.

To empty the thorax, in a rupture of any vessels which open into it, bleeding is very necessary; which not only stops the hæmorrhage, by abating the force of the circulation; but likewise, by unloading the vessels of their contents, makes them more fit to receive the extravasated fluid by absorption: gentle evacuations and pectorals are also very serviceable, and a low diet is absolutely necessary.

The second circumstance in which this operation takes place, is a rupture of matter from the *pleura mediastinum* or lungs into the cavity of the thorax, where accumulating it at length proves fatal for want of a discharge. It is true, that the case occurs but very seldom, where the operation is necessary; because, in most abscesses of the thorax, the matter

matter is usually spit up as fast as it is generated; and in the dissection of such who have died of this species of consumption, we rarely find much extravasated *pus* in the cavity, though a great portion of the lungs be destroyed. However, there are a few examples which require the operation: and these may be distinguished by the following symptoms. The patient is obliged to lie upon the diseased side, or, in case there is matter in both cavities of the thorax, on his back; because the *mediastinum* can seldom support the weight of the incumbent fluid, without suffering great pain; but this rule is not certain, it sometimes happening that the patient can lie with ease on that side where there is no fluid. Another symptom of extravasated matter, is an evident undulation of it, so that in certain motions it may be heard to quash. For the most part too, upon careful inquiry, an *edema*, or at least a thickening of some portion of the intercostal muscles, will be discovered. And lastly, if there be much fluid, it will be attended with a preternatural expansion of that side of the chest where it lies. When therefore these signs appear after a previous pleuritic or pulmonary disorder, and the case has been attended with the symptoms of a suppuration, it is most probably owing to a collection of matter; though the patient will also labour under a continual low fever, and a particular anxiety from the load of fluid.

The last sort of fluid said to require issue from this operation is water, which however very seldom collects in such manner as to become the proper subject of the operation: for if the dropsy of the thorax be complicated with an *anasarca*, or even *ascites*, it is certainly improper; and indeed it hardly ever takes place, but where the distemper is single, and takes its rise from the same sort of disorders in the lymphatics of the pleura, as the hydrocele does from those of the *tunica vaginalis*. The symptoms of this dropsy are, a small cough without spitting, a little slow fever from the disturbance of respiration; sometimes too the water, by a sudden jerk, may be heard to quash; and, generally speaking, its weight upon the *diaphragm* and *mediastinum* are so troublesome as to oblige the patient to stoop forward, and to turn upon the affected side when he lies down; for the same reason, when there is water in both cavities of the thorax, he is forced to lie on his back.

The manner of operating, whether it be for the discharge of matter or water, is to pitch upon the most depending part of the thorax, which some have supposed to be between the eighth and ninth rib, and others between the ninth and tenth, at such a distance from the *vertebrae* that the depth of the flesh may not be an impediment to the perforation. This distance is determined to be about a hand's breadth: and here, with a knife, scissars, or trocar, we are ordered to make the perforation; but in doing it there are a great many difficulties. In fat persons, it is not easy to count the ribs, and the wound will be very deep, and troublesome to make; it is hardly possible to escape wounding the intercostal artery, which runs in this place between the ribs. But if the only advantage proposed by the situation of the wound be derived from its dependency, the purpose of discharging the fluid will be as well answered by an opening between the sixth and seventh rib, half way from the sternum towards the spine; which, by laying ourselves down, becomes in effect as depending an orifice, as the other in sitting up; and by an opening made in this manner we avoid all the inconveniences in the other method: For in this part of the thorax

there is very little depth of muscles; the artery lies concealed under the rib; and the diaphragm is at great distance. The opening is best made with a knife, and should be about an inch long through the skin, and half an inch through the subjacent muscles; though, to make the incision with less risk of wounding the lungs, it may be advisable to dilate it with the blunt-pointed knife (as is practised in the operation for the *bubonocoele*) after having made a small puncture with a common knife. The treatment of the wound will be according to the nature of the discharge. If, after a few days, there appears no drain, you may let the orifice heal up; but if it continues, it may be kept open with a short silver canula, until such time as an alteration in that circumstance will give us leave to cicatrize with safety.

Of Encysted Tumours.

THESE tumours borrow their names from a cyst or bag, in which they are contained; and are farther distinguished by the nature of their contents: If the matter forming them resembles milk-curd, the tumour is called *atheroma*; if it be like honey, *meliceris*; and if composed of fat, or a stony substance, *steatoma*. The two first are not readily distinguished from one another, but their difference from the *steatoma* is easily learnt by their softness and fluctuation. These tumours appear in every part of the body, and in places where there are no glands.

The *steatoma* is never painful until by its weight it grows troublesome, nor is it a mark of general indisposition of body; so that the extirpation seldom fails of success. The size of some of them is very large, frequently weighing five or six pounds, and there have been instances of their weighing above forty.

When the *steatoma* is irregular in its surface, with eminencies and depressions, it is stony; whereas the fat one has for the most part a uniform smooth outside. The operation for the *steatoma* will be understood by the description of that for the *schirrhus*.

The *atheroma* is much more common than the *meliceris*; at least, if all encysted tumours with matter not curdled, may, in compliance with custom, be called so: These are more frequent, and grow larger than those where the matter is curdled, being often attendant on scrophulous indispositions, which makes them more difficult of cure.

The cysts of these tumours, with the skin covering them, after a certain period of growth, resisting any further enlargement, do frequently inflame and break; but this opening is not so advantageous for the cure as extirpation by the knife, which should be done in the infancy of the swelling. When the tumours are no bigger than a small golden pippen, they may be dissected away from under the skin, by making a straight incision only through it; but if they exceed this bulk, an oval piece of skin must be cut through first, to make room for the management of the knife and taking away the tumour; in which case, it will be advisable to take off the upper portion of the cyst with the skin; and then, by the help of a hook, to dissect away as much of the remainder of it as can be conveniently, which is a less painful and more secure method than destroying it afterwards with escharotics. This rule is to be observed, when the cyst runs so deep amongst the interstices of the muscles, as to make it impossible to remove the whole of it, where, if we cut off a great quantity, the rest usually comes away in sloughs and matter.

The ganglion of the tendon is an encysted tumour of the

meliceris kind, but its fluid is generally like the white of an egg; when it is small, it sometimes disperies of itself; pressure and sudden blows do also remove it; but for the most part it continues, unless it be extirpated. It is no uncommon case to meet with this species of ganglion, running under the *ligamentum carpalæ*, and extending itself both up the wrist and down to the palm of the hand. The cure of this disorder cannot be effected but by an incision through its whole length and dividing the *ligamentum carpalæ*.

The dressing in these cases does not at all differ from the general methods of treating wounds.

Of the Amputation of the Cancered and Scirrhus Breast.

THE success of this operation is exceedingly precarious, from the great disposition there is in the constitution, after an amputation, to form a new cancer in the wound, or some other part of the body. When a scirrhus has admitted of a long delay before the operation, the patient seems to have a better prospect of cure without danger of a relapse, than when it has increased very fast, and with acute pain.

The scirrhus may be distinguished, by its want of inflammation in the skin, its smoothness and slipperiness deep in the breast, and generally by its pricking pain, which as it is more or less, increases the danger accordingly; though there are some few with little or none in the beginning: as the tumour degenerates into a cancer, which is the worst degree of scirrhus, it becomes unequal and livid, and the vessels growing varicose, at last ulcerates.

In extirpating the scirrhus, if it be small, a longitudinal incision will dilate sufficiently for the operation; but if too large to be dissected out in that manner, an oval piece of skin must be cut through first, the size of which is to be proportioned to that of the tumour; for example, if the swelling is five inches long, and three broad, the oval piece of skin cut away must be nearly of the same length, and about an inch and a half in breadth. In taking off the whole breast, the skin may be very much preserved, by making the wound of it a great deal less than the basis of the breast, which must be carefully cleared away from the pectoral muscle. This is not difficult to do, because all these scirrhuses being enlarged glands, are encompassed with their proper membranes, which make them quite distinct from the neighbouring parts, and easily separable; at least this is the case when the tumour is moveable; for sometimes it adheres to the subjacent muscle, and that muscle to the ribs; in which circumstance, the operation is impracticable. When it is attended with knots in the arm pit, no service can be done by amputation, unless the knots be taken away; for there is no sort of dependence to be laid on their subsiding, by the discharge of the wound of the breast.

The bleeding of the large arteries is to be stopped by passing the needle twice through the flesh, almost round every vessel, and tying upon it, which will necessarily include it in the ligature. In order to discover the orifices of the vessels, the wound must be cleaned with a sponge wrung out of warm water.

The scirrhus tumours which appear about the lower jaw, are, generally speaking, cerophalus disorders, that distinguish themselves almost by the circumstance of fixing on the salivary glands. These are very stubborn of cure, but not so bad as the scirrhus, since they frequently suppurate, and heal afterwards: if they imposthumate again after heal-

ing, it is for want of a good bottom, which may sometimes be procured by destroying their bad surface with a caustick. Besides these, there is another species of scirrhus in the neck, that succeeds better after extirpation than either of the former kind; this is an enlargement of the lymphatick glands, which run close up to the jugular vein, and is distinguishable from the cancers of this part, by its moveableness, want of pain, the laxness of the skin covering it, the small degree of pressure it makes on the *œsophagus* and *trachea*, and lastly the good habit of body, as it seldom affects the constitution, which cancers here do very early, after their first appearance. This tumour, from its situation, requires great exactness in the cutting off: they sometimes extend up to the chin towards the mouth, and occasion a division of the salivary duct in operating, which proves very troublesome to heal; but, when all other methods have failed, may be cured by a perforation into the mouth, through that part of the cheek where it is wounded, which by a tent or small seton may be made fistulous; then, by properly dressing upon the outside, the oozing of the *saliva* that way will be prevented, and the external orifice healed without difficulty.

The treatment of all these wounds may be with dry list first, and afterwards as in common wounds.

Of the Operation of the TREPAN.

THE operation of the *trepan*, is the making one or more orifices through the skull, to admit an instrument for raising any pieces of bone that by violence are beaten inwards upon the brain, or to give issue to blood or matter lodged in any part within the *cranium*.

Fractures of the skull are at all times very dangerous, not in consequence of the injury done to the *cranium* itself, but as the brain becomes affected either from the pressure of the fractured bone, or that of the extravasated blood and matter. If then the symptoms excited by a fracture do sometimes follow from a mere extravasation of blood, as is the case when the *cranium* is not beaten inwards, it must likewise happen that a rupture of the vessels of this part, without a fracture, will also occasion the same disorders: For this reason, the operation may take place where the skull is not much offended, but only the vessels of the *dura mater*, the *pia mater*, or the brain.

When the *cranium* is beaten inward, without any fracture, it is called a depression; when very much broken, a fracture; or if broken and beat in also, a fracture with depression; if it is only cracked without depression, though properly a fracture, it is called a fissure; if none of these disorders appear, where there is a suspicion of them, the symptoms are imputed to a concussion of the brain. These are the four distinctions in use, and which fully comprehend all the others.

The depression of the *cranium* without a fracture can but seldom occur, and then it happens to children whose bones are more pliable and soft than those of adults.

In blows of the *cranium*, requiring the use of the *trepan*, the marks of a fracture are generally very evident, since the scalp is often lacerated so much, as to expose it to our sight: But if the wound of the scalp be so small, as only to admit a probe, we must judge then by the feel of the surface of the bone, using the caution of not mistaking a future for a fracture.

If there be no wound of the scalp, you must press about the

the head with your fingers, till the patient complains of some particular part, which in all likelihood is the place affected; and, if the scalp there be separated from the *cranium*, is almost infallibly so. The symptoms of a fracture, are, a bleeding at the ears and nose, a loss of sense, vomitings, drowsiness, delirium, incontinence of urine and excrement; but what is most to be depended upon, is a depression of the bone, or a roughness on its outside: for all the other complaints not only happen to concussions, which do well without the application of a trepan, but likewise there are fractures not attended with any of them, or at least in a slight degree; so that these symptoms alone, without examination of the part affected, are but an uncertain rule to go by.

In concussions without a fracture, that produce the symptoms here laid down, and do well afterwards, the vessels of the brain and membranes are only inflamed and dilated; or if they are ruptured, they absorb the extravasated blood again; on which account, nature should be assisted by plentiful bleedings, clysters, and other evacuations, and so in all fractures where the patient is not trepanned immediately: however, although people with violent concussions do sometimes recover, it is so very seldom, that there can be no pretence, when they happen, for neglecting the trepan, but not being able to learn in what part the concussion is.

Writers dispute very much about the possibility of the *centra fissure*, or a fissure occasioned on the part of the head opposite to that on which the blow is given, or where the inner table is fractured while the outer one remains entire; but there are histories of cases, which, if fairly stated, make it unquestionable; and this is most certain, that if the complaint be at a distance from where the blow was received, there can be no danger in sawing, and applying the trepan to that part where the pain is.

When we are assured of a fracture or depression, it is always advisable to trepan as soon as possible, in order to prevent the spreading of the abscess, which seldom fails to follow upon the rupture of the vessels of the brain and membranes, and for the most part in a few days.

The manner of treating a fracture of the *cranium*, will be according to the nature of the fracture itself, and the injury of the scalp. If the wound of the head be torn into angles, perhaps cutting off the lacerated flaps will make room for the saw; if the bone be broken into several pieces, the pieces may be taken away with the forceps; or if some of the pieces of the skull be also depressed, the removal of the pieces will, without perforating, make way for the elevator to raise the depressed part; but if the fracture be not complicated with a wound of the scalp, or the wound be too small to admit of the operation, which seldom fails to be the case, then the fracture must be laid bare, by taking away a large piece of the scalp.

Before the application of the trepan, it is to be remembered there are certain places on the skull where it cannot be used with so much safety as on others; the whole length of the sagittal suture, down to the nose, is always mentioned as one where the perforation is dangerous, because of the spine of the *os frontis*, and the course of the superior longitudinal *sinus* under this part, which it is supposed would be necessarily wounded by the saw, and in consequence destroy the patient by the hæmorrhage: but though a perforation may, contrary to the general opinion, be made over the *sinus* without offending it, and, even if it was wounded, the effusion of blood would not in all probability be mortal;

yet at best it would be very troublesome; and since we are not straitened in that part of the *cranium* for room, it is advisable to forbear operating in this place. The bony *sinus* of the *os frontis* forbid the use of the trepan near the orbits of the eyes; therefore, if it should be depressed near those cavities, the surgeon must be careful to perforate either above, or on one side of the fracture; for sawing below it will only lead into the *sinus*, and answer no purpose in the design either of giving a discharge to the matter from the brain, or an opportunity to elevate the depression; nay, perhaps leave an incurable fistula, if the patient escapes with life.

The *os occipitis* being very uneven, both in its internal and external surface, makes trepanning there almost impracticable; besides, the great *sinules* run about so much of it, as hardly to afford space to perforate without danger of wounding them; but then it is so defended from injuries by its situation and strength, that fractures do not happen to it so often as to the other bones of the *cranium*; and when they do, for the most part they become so soon mortal, by affecting the *cerebellum* which it sustains, that the operation is seldom required in this case. Indeed the upper angle of this bone lies above the *cerebellum*, and when fractured or depressed, is not attended with so immediate danger; but when this happens, the course of the longitudinal *sinus* down the middle of it, and the neighbourhood of the lateral *sinuses* beneath it, make it advisable to trepan at the lower part of the *os parietale*, or at least upon or just below the lambdoidal suture, so that the perforation of the *os occipitis* can hardly ever be proper.

Though wounds in the *cerebellum* are always mortal, yet great portions of the cerebrum have been carried off, or destroyed, without any notable inconvenience.

The places then unfit to admit the saw, are the three described; that is, the sagittal suture; that part of the *os frontis* near the orbits of the eyes; and the *os occipitis*. But when a fracture happens in any other part above the ear, there is no objection to the operation. When there is only a small fissure without any depression or motion in the bone, the trepan may be applied on the fissure itself, which will more readily give vent to the blood or matter underneath, than if made at a distance. If the fissure be large, and the bone weakened or depressed, the trepan must be applied on one side of it, but so as to make it a part of the circumference of the sawed piece; if the fracture run upwards, it will be eligible always to perforate near its bottom, because the dependency of the orifice will give better issue to the matter, though the ill-grounded apprehension of the brain falling out there has made many eminent surgeons contradict this rule in their practice. If, by making one orifice, you cannot raise all the depressed part, you must make a second and a third, and continue doing so, till you have reduced the whole *cranium* even: there is frequently occasion to repeat it twice or thrice; and it has been done twelve times, you oftener, with success; which shews the little danger there is, either in sawing the skull, or exposing the *dura mater* and brain, when the pressure is taken off. Indeed the mischief of laying the brain bare, is so small, compared with a concussion of it, or an abscess from pent-up matter, that those fractures of the skull where the bone is broken into splinters the whole extent of it, and can be taken away, much more readily do well, than a simple fissure only, where the abscess cannot discharge itself freely; for

which reason, though the depressed fracture may be raised by the means of one orifice, yet, if it is of a considerable length, it will be almost absolutely necessary to make one or two more openings, for the convenience of discharge; since, for want of this, we see abscesses increase daily in their quantity of matter, and at the end of a few weeks carry off the patient.

In concussions of the brain without a fracture of the cranium, if the trepan be applied, and vast discharges ensue, it will be also convenient to make more perforations into the abscess and the neighbourhood of the abscess, the situation of which will be easily guessed by the direction of the stream of matter. And here it is to be observed, that abscesses which ensue from a concussion are generally more extensive and dangerous than those which accompany a fracture with depression: for in a fracture, the yielding of the bone destroys, in a great degree, the force of the striking body, and prevents any violent commotion of the brain; so that what the brain suffers results chiefly from the pressure of the incumbent bone, and the laceration of the vessels, near the fracture: whereas, when the cranium resists the shock, all, or great part of the *cerebrum* sustains the concussion, and is often impotumated or inflamed almost in its whole dimension.

The manner of trepanning is this: Having fixed your patient's head steady, either on the bolster of a bed, or by placing him in a low chair; with the pin of your saw, mark the center of the piece of bone to be taken out; then with the perforating trepan, make an orifice deep enough to receive the pin, which being fixed in it will prevent the saw from slipping; and thus you are to continue sawing, till the impression made will preserve the steadiness without the pin, when it is to be taken away, for fear of its wounding the brain before the saw has entered through the cranium, which it would do at last, because of its projection. In working through the bone, the teeth of the saw will begin to clog, by that time you arrive to the *diploe*; wherefore a brush must be ready to clean it every now and then, and with a pointed probe you must clear away the dust in the circle of the trepanned bone, observing, if it be deeper on one side than the other, to lean afterwards on that side where the impression is least, that the whole thickness may be sawed through at the same time. To do all this with less interruption, it will be proper to have two saws of exactly the same diameter, that an assistant may be brushing one while you operate with the other. We are advised to saw boldly till we come to the *diploe*, which, it is said, will always distinguish itself by the bloodiness. But, however, this is not a certain mark to go by: for though, where there is a *diploe*, it will manifest itself by its bloodiness, yet sometimes the skull is so very thin as not to admit of any; in which case, if an operator should push on his instrument in expectation of meeting with this substance, he would unwarily wound the brain. This is not very often the case; but, however, often enough to put a man on his guard, and make him inquire whether the bone be loose after a little sawing, which is the only rule we go by when we have passed through the *diploe*, and may as well be attended to before coming at it, without any considerable loss of time. When it is quite sawed through, and lies loose, it may be taken away with the forceps contrived for that use; and if the lower edges of the orifice, next to the *dura mater*, are splintered, they may be scraped smooth with a lenticular.

These are the chief processes of the operation of the trepan. The only thing remaining to be done is, with an elevator introduced at the orifice, to raise the depression, or broken splinters, if they cannot otherwise be laid hold of, and to draw out the grumous blood, or any other extraneous body. If the *dura mater* be not wounded or torn, an incision must be made through it, to give way to the blood or matter, which almost certainly lie underneath it, if the symptoms have been bad, and none has been discharged from between the *cranium* and *dura mater*: Though it has been lately observed, that an abscess will sometimes be formed in the substance of the brain; and therefore, if the puncture of the *dura mater* does not procure an evacuation of the matter, and the symptoms of a suppuration are still urgent, it will be advisable to make a small incision with a lancet into the brain itself.

We have used the word trepan all along, for the sake of being better understood; but the instrument here recommended is a trephine; the advantages of which, as also that of a cylindrical saw, or one nearly cylindrical, are described in the explanation of the copper-plate.

With regard to the dressings of these wounds, it is very certain, that as the greatest part of the evil proceeds from the quantity and pressure of the matter, whatever approaches towards the nature of a tent, and increases its quantity and pressure by locking it up, must be pernicious. Therefore the use of all lyndons whatever should be excluded. The hasty application too of spirits of wine, which is so commonly advised, cannot be proper; as they are not only unfit for inflammations in general, but also crisp up the vessels of the *dura mater* and brain, and, stopping the suppuration, sometimes produce a gangrene. Since then a close application is inconvenient, and, whatever good there may be in topical medicines, it cannot for the most part be communicated to the abscess, by reason of its extent beyond the orifice, the best remedy will be dry lint only, which must be laid on loosely to give vent to the matter, and be repeated twice a day till the discharge is lessened, when once in twenty-four hours will be sufficient to the finishing of the cure, which will be something retarded by the exfoliations that sometimes follow this operation. The patient afterwards may wear a plate of tin upon the scar, to defend it from blows or any accidental injury.

EXPLANATION of Fig. 1. Plate CLVIII.

A, The perforator, commonly called the perforating trepan. With this instrument, an orifice is usually made for the reception of the pin, on the centre of the piece of bone that is to be taken away, in the operation of trepanning; though if the pin be very sharp, and project but little beyond the teeth of the saw, as in that marked with the letter *B*, the perforator would be needless; but as the point of the pin presently grows blunt with use, and in that case it is difficult to fix the saw, it is advisable to have this instrument in readiness. It is also handy for boring into the substance of the bones, in order to promote a granulation of flesh on their surfaces. When it is made use of, it must be received and fastened in the handle *C*.

B, The crown, or saw of the trepan, with the pin appearing just beyond the extremities of the teeth. The shape of this saw is cylindrical.

C, The handle of the foregoing instrument, called the trephine; which is much preferable to the trepan, (an instrument like a wimble used by joiners,) because of the great

great convenience of holding it, and leaning on one side or other of the saw, as we find it necessary: The trepan however, though allowed to be unhandy, is the instrument most used by surgeons in other parts of Europe, upon the supposition of its working quicker than the trephine.

The trephine here represented is of such a shape as to make it a convenient elevator, for which purpose the extremities of it are made rough.

D, A key to take out the pin E, when the saw has made an impression deep enough to be worked without the help of it.

EXPLANATION of Fig. 2. Plate CLVIII.

A, A convenient forceps to take out the circular piece of bone, when it does not stick to the saw: the contrivance by which they readily lay hold of it, is to make the extremities that are to grasp it, with an arch of the same circle as the saw is made. Upon one of the handles, there is added a little elevator, to lift up any small splinter of bone.

B, A lenticular: the fore-part of its blade is sharp, in order to scrape the lower edge of the orifice of the *cranium*, in case any splinters should remain after the operation; and the button at its extremity receives the dust, that it may not fall on the brain; but there is seldom any occasion for this instrument.

C, A rugine or raspator, for scraping bones in order to promote granulations of flesh. The handles of these two last instruments are wood, whereas every part of the others should be made of steel.

Of the CATARACT.

THE cataract, called by the Latins *suffusio*, is a disease of the crystalline humour, rendering the whole body of it opaque, so that the rays of light, which, in the natural state of its transparency, were transmitted to the *tunica retina*, become now totally intercepted, and produce no effect. This is pretty nearly the account delivered down to us by Hippocrates and the ancient Greeks, who likewise knew it by the name of *glaucoma*.

Anatomists have frequently dissected the eyes of persons under this disorder after their death, and have found it to be always an opacity of the crystalline humour, agreeably to the definition of a *glaucoma*: so that by consequence we must understand the words *cataract* and *glaucoma* as synonymous terms.

The general criterion of the fitness of cataracts for the operation, is taken from their colour; the pearl coloured, and those of the colour of burnished iron, are esteemed proper to endure the needle; the white are supposed milky, the green and yellow horny and incurable.

The depression of a cataract of any colour would be the cure, if that alone was the distemper of the eye: but it generally happens, that the yellow cataracts adhere to the *iris* so firmly as to become immoveable; besides, when they follow in consequence of a blow, which is often the case, either the cells of the vitreous humour are so much disturbed and broken, or the *retina* affected, that a degree of blindness will remain, though the cataract be depressed.

To judge whether the cataract adheres to the *iris*, if you cannot at once distinguish it by your sight, shut the patient's eye, and rub the lids a little: then suddenly opening it, you will perceive the pupil contract, if the crystalline humour does not prevent the action by its adhesion: And

when this is the case in any kind of cataract, the operation can hardly be advised.

Another consideration of the greatest moment, before undertaking the cure, is to be assured of the right state of the *tunica retina*; which is very readily learnt, where there is no adhesion of the cataract, from the light falling between the *iris* and crystalline humour, which if the eye is not sensible of, it is a certain indication of another malady, and absolutely forbids the operation. Generally this cataract takes its rise from head-achs, convulsions, and nervous disorders.

When none of these objections forbid the operation, it may be thus done: Having placed your patient in a convenient light, and in a chair suitable to the height of that you yourself sit in, let a pillow or two be placed behind his back. In such a manner, that the body bending forward, the head may approach near to you; then inclining the head a little backward upon the breast of your assistant, and covering the other eye so as to prevent its rolling, let the assistant lift up the superior eye-lid, and yourself depress a little the inferior one: This done, strike the needle through the *tunica conjunctiva*, something less than one tenth of an inch from the *cornea*, even with the middle of the pupil, into the posterior chamber, and gently endeavour to depress the cataract with the flat surface of it. If, after it is dislodged, it rises again, though not with much elasticity, it must again and again be pushed down. If it is membranous; after the discharge of the fluid, the pellicle must be more broke and depressed: if it is uniformly fluid, or exceedingly elastic, we must not continue to endanger a terrible inflammation, by a vain attempt to succeed. If a cataract of the right eye is to be couched, and the surgeon cannot use his left hand so dexterously as his right, he may place himself behind the patient, and use his right hand.

We have not recommended the *speculum oculi*, because, upon the discharge of the aqueous humour through the puncture, the eye, being somewhat emptied, more readily admits of the depression of the crystalline humour, than when pressed upon by the instrument.

As to the method of treating the succeeding inflammation, bleeding and other gentle evacuations are found absolutely necessary.

Of Cutting the Iris.

THERE are two cases where this operation may be of some service; one when the cataract is from its adhesion immoveable; and the other, when the pupil of the eye is totally closed up by a disorder of the muscular fibres of the *iris*, which gradually contracting the orifice, at last leaves the membrane quite imperforate. This last distemper has hitherto been deemed incurable. The adhesion of the cataract has been considered as a species of blindness not to be relieved: but Mr *Chefelden* has invented a method of making an artificial pupil, by slitting the *iris*, which may relieve in both the instances here stated.

In doing this operation, the patient must be placed as for couching, and the eye kept open and fixed by the *speculum oculi*, which is absolutely necessary here; then introducing the knife in the same part of the *conjunctiva* you wound in couching, insinuate it with its blade held horizontally, and the back of it towards you, between the *ligamentum ciliare* and circumference of the *iris*, into the anterior chamber of the eye; and after it is advanced to the farther side of it,

make your incision quite through the membrane; and if the operation succeeds, it will upon wounding fly open, and appear a large orifice, though not so wide as it becomes afterwards.

The place to be opened in the *iris*, will be according to the nature of the disease: if the membrane itself be only affected with a contraction, the middle part of it, which is the natural situation of the pupil, must be cut; but if there be a cataract, the incision must be made above or below the cataract, though it is more eligible to do it above.

The contracted *iris*, from a paralytic disorder, is so often complicated with an affection of the *retina*, that the success is very precarious in this case. This operation has answered best in adhesions of the crystalline humour, though but very seldom even there.

EXPLANATION of Fig. 3. Plate CLVIII.

A, The couching needle, the broad part of which towards the point is flat on one side; but on the other is a little convex. to give it more substance and strength.

The handle of this instrument is white ivory, inlaid with a streak of black in that part of it lying even with the convex surface of the blade: The meaning of which is, that by holding the handle with the streak upwards; we may be guided to depress the membrane of a milky cataract with the flat surface, though the substance of the cataract swimming in the eye obscures the needle, and prevents its being directed in a proper position by the sight.

B, A *speculum oculi*, which is made to open or shut by an iron button sliding along a slit in the handle. This instrument is composed of one piece of steel, in such a manner that it would fly open by its elasticity, if the two branches of the handle were not confined by the button. The circle of it should be covered with velvet, to make it lie softer on the eye-lids.

C, The knife for cutting the *iris*, the blade of which has two edges, resembling a lancet, which are more advantageous than one only, in cutting the *cornea* for the extraction of the cataract.

Of the FISTULA LACHRYMALIS.

The *fistula lachrymalis* is generally understood to be such a disorder of the canals leading from the eye to the nose, as obstructs the natural progress of the tears, and makes them trickle down the cheek: but this is only the first and mildest stage of the disease. In the next, there is a nucleus resembling matter, and afterwards matter itself discharged with the tears from the *puncta lachrymalia*, and sometimes from an orifice broken through the skin between the nose and angle of the eye. The last and worst degree of it is, when the matter of the abscess, by its long continuance, has not only corroded the neighbouring soft parts, but also affected the subjacent bone.

Monsieur Ansell, a French surgeon, recommends in the recent fistula, to pass a small probe through one of the *puncta lachrymalia* into the *sacculus* and nose, in order to break the concretions which were supposed to make the obstruction, and with a small pipe and syringe to throw an injection through the other, in order to wash them away.

The manner of operating in those cases where perforation is not required, is this: Supposing the abscess not broken, chuse a time when it is most turgid with matter; and to his end, you may shut the patient's eye the day before,

and lay little slips of plaister upon one another across the lids, from about the *puncta lachrymalia* to the internal angle; which compressing their channels, and preventing the flux of the matter that way, will heap it up in the bag, and indicate more certainly the place to be cut. If the abscess is already open, the orifice and probe will inform you where to enlarge: then placing the patient in a seat of convenient height for the management of your hand; with a small incision-knife dilate from the upper part of the bag, down to the edge of the orbit, without any regard to the tendon of the orbicularis muscle, or fear of wounding the blood-vessels; though if you see the vessels, it is proper to shun them. The length of this incision, will be near four tenths of an inch. It has been advised, in opening the bag, to introduce a small probe through one of the *puncta* into its cavity, to prevent wounding the posterior part of it. But this excess of care may be more troublesome than useful; since, in so large a vessel, a very small share of dexterity is sufficient to avoid the mistake. In making this incision, care must be had, not to cut too near the joining of the eye-lids, because of the deformity of the succeeding scar; though the blear eye or uneven contraction of the skin in that part, after the operation, is generally owing to the use of the caustery, and not to the wound of the tendon of the orbicularis muscle; for this last is necessarily from its situation always cut through, but without any inconvenience, because of the firm cicatrix afterwards that fixes it strongly to the bone.

When the bag is open, it is to be filled with dry lint, which the next day may be removed, and exchanged for a dofsil dipt in a soft digestive medicine: this must be repeated every day once or twice, according to the quantity of the discharge; now and then, when the matter is not good, using the precipitate medicine, and from time to time a sponge-tent, to prevent the too sudden reunion of the upper part of the abscess. When the discharge begins to lessen, it will be proper to pass a small probe, a small bougie, or silver wire, through the nasal duct into the nose every time it is dress'd, in order to dilate it a little, and make way for the tears and matter which by their drain will continue to keep it open. This method must be followed till the discharge is nearly over (which will be in a few weeks;) and then dressing superficially with dry lint, or any drying application, the wound will seldom fail of healing. After the cure, in order to prevent a relapse, it will be proper, for a few weeks, to wear the compressing instrument represented in the copperplate.

When the bone is bare, and the fistula requires perforation, the perforator is not to be carried down the *ductus ad nasum*, for fear of boring into the *sinus maxillaris*; but more internally towards the nose, which will bleed freely, if properly wounded. The wound afterwards should be dress'd with dofsils, in the manner above described, and the probe or silver wire be every day pass'd through the *ductus ad nasum*, lest, after the cure of the abscess, it should still remain obstructed; and if, upon trial, the duct should be so fill'd up as not to admit the wire, it will be right to keep open the perforation into the nose with a small tent, till the discharge is almost quite ceased.

EXPLANATION of Fig. 4. Plate CLVIII.

A, The eye, with the skin of the eye-lids denuded, in order to shew the orbicularis muscle: the white streak running from the inner angle of the eye toward the nose is the tendon

tendon of the orbicularis muscle. At a little distance from the internal angle, on the edge of the eye-lids may be observed two black spots, which are the orifices of the lachrymal channels, and called the *puncta lachrymalia*.

B, The exact dimension of the lachrymal channels and bag; the pricked line represents the edge of the orbit.

C, A small incision-knife, more handy than a larger for opening the bag.

D, The perforator to destroy the *os unguis*, if ever it should happen to be necessary.

E, An iron instrument made thin and pliable, to set even on the forehead, and for use covered with velvet: the holes at the three extremities receive two pieces of ribband, by which it is fastened on the forehead: the button at the end of the screw is to be placed on the *sacculus lachrymalis*, and the screw to be twilted till the button makes a considerable pressure on the bag: the button should be covered with velvet, and a little compress of plaister be laid on the bag before it is applied, to prevent the skin from being galled by the pressure. The little branch of iron which receives the screw must be soft enough to admit of bending, otherwise it will be difficult to place the button exactly on the bag. This instrument is for the left eye only; it should be worn night and day in the beginning of a fistula, and after a fistula has been healed by incision; but as the success depends upon the exact situation of the button upon the bag, it should be carefully looked after.

Of BRONCHOTOMY.

THE operation of *bronchotomy* is an incision made in the *aperta arteria*, to make way for the air into the lungs, when respiration is obstructed by any tumour compressing the *larynx*, or some other disorder of the *glottis* and *aperta arteria*, without any apparent tumour.

The manner of doing it, is by making a longitudinal incision through the skin, three quarters of an inch long, opposite to the third and fourth ring of the trachea, if you have the choice of the place; and when you cannot make it so high, the rule will be to wound a little below the tumour: it is always advised to pinch up the skin for this process, which however may be left to the discretion of the surgeon. When the skin is cut through, you must make a small transverse incision into the wind-pipe, and immediately introduce a silver crooked *canula* near half an inch long, with a couple of little rings at the top of it, through which a ribband may be passed round the neck, to keep it fixed in the wound.

The method of dressing will be easily understood; since, after the patient can breathe by the natural passage, if you withdraw the hollow tent, the wound will become a simple one. and, notwithstanding its penetration through a cartilage into a large cavity, require a superficial application only.

Of the Extirpation of the TONSILS.

THESE glands sometimes grow so large and scirrhus as to become incurable, and even to threaten suffocation if not extirpated. The manner of doing this operation formerly, was by cutting them off: but the almost constant consequence of this wound was a violent bleeding, and sometimes too a mortal one; on which account it is rejected in favour of the ligature, which is not only void of danger, but also seldom fails of cure.

If the basis of the tonsil is smaller than the upper part, you may pass the ligature by tying it to the end of a probe, bent into the form of an arch, and set into a handle; which being carried beyond the gland, and round it, is to be brought back again: this done, you may easily tie it by the means of an instrument of Mr. Cheselden's contrivance, which holds one end of the string on the side of the tonsil next the throat, while you make the knot by pulling the other with the right hand quite out of the mouth, as will be easily understood by the draught in the copper-plate. Should it happen that the tonsils are conical, so that the ligature will necessarily slip over its extremity when we attempt to tie; in this case, he has recommended an instrument like a crooked needle, set in a handle, with an eye near the point, threaded with a ligature, which is to be thrust through the bottom of the gland, and being laid hold of with a hook, the instrument is to be withdrawn; then pulling the double ligature forwards, it must be divided, and one part be tied above, and the other below the tumour: the knots are to be always double, and the ligature to be cut off pretty near them.

If after four or five days they slip, or seem to have mortified the tonsil only in part, you must repeat the whole operation; and if it fail a second time, you must even repeat it again.

This kind of extirpation is more practised in large piles, that are esteemed incurable. When the piles are within side of the intestine, you must place your patient over a fomentation in a closet stool, and have a crooked needle with a double ligature ready to pass through them, when by straining they are pushed out of the *anus* (for sometimes the intestine will return suddenly,) and tie above and below as in the instance of the tonsil. Sometimes the piles are of that shape as to admit a single ligature to be tied round them without the help of a needle, which is less painful. If there are several, you must only tie one or two at a time; for the pain of the ligature is excessive, and would be intolerable if many were tied at once: however, every five or six days, the operation may be repeated till all are extirpated, and the parts must be kept supple by some emollient ointments.

When the piles are small, they may safely and with much less pain be cut off.

The *uvula* is subject to so great a degree of relaxation sometimes, that it almost chokes the patient; the readiest cure is cutting off all but half an inch of it, which may be done at one snip with a pair of scissors (particularly curved for that purpose,) laying hold of it with a forceps, lest it should slip away.

EXPLANATION of Fig. 5. Plate CLVIII.

A, The bent probe fixed in a handle, with the ligature made of the same thread as the ligatures for tying the blood-vessels.

B, The iron instrument for tying the tonsils.

This instrument is also of great service in extirpating, by ligature, a species of scirrhus that sometimes grows from the neck or cavity of the *uterus*.

C, The needle with the eye towards the point, for passing the ligature through the tonsil, when the basis is larger than the extremity.

D A *canula* made of silver to be used in the *empyema*.

E, A *canula* to be used in *bronchotomy*.

To keep the *canulas* in their place, small ribbands may be

be passed through the rings of them, and carried round the body and neck; or they may be held by a ligature run through, and fastened to a hole cut in a piece of sticking plaster, which is to be laid on each side of them.

Of the POLYPUS.

THE polypus of the nose, is said to be an excrescence of flesh, spreading its branches amongst the *laminae* of the *ethmoides*, and through the whole cavity of one or both nostrils. It happens very often to both sides of the nose at once; and in that case is very troublesome, almost suffocating the patient, at least making respiration very difficult. The intent of the operation is the removal of this obstacle.

Polypi arise from the membrane spread upon the *laminae spongiosae*, pretty nearly in the same manner as the *hydatis* of the *abdomen*, in one kind of dropsy, do from the surface of the liver; or as ganglions from the tendons, borrowing their coats from a production of its fibres and vessels: If they appear soft, and of the colour of the serum of the blood, in all likelihood they are formed of such a sort of water contained in cysts, which, upon breaking the membrane, leaves so little hold for the instrument, that but a small part of it can be extracted afterwards. This *polypus* is to be left to harden, before the operation be undertaken, which in process of time it generally will do. In the next degree of consistence, they retain pretty nearly the same colour, and are often partly watery, and partly of a viscid texture, which though not tenacious enough to admit of drawing them out by the roots, may at several attempts be taken away by bits. The next degree of consistence, is that which is neither so soft as to be squeezed to pieces, nor so hard and brittle as to crumble, or adhere to the membrane with that force as not to admit of separation: this is the most favourable one. The last, is hard and scirrhous, adhering so tight as to tear rather than separate in the extraction, and sometimes even tends to degenerate into a cancer: This *polypus* is very difficult of cure.

The *polypus* sometimes dilates to that degree, as not only to extend beyond the *os palati*, and hang over the *æsophagus* and *trachea*; but also spreading into the *sinus maxillaris*, so exactly fills up every interstice of the nose, as to obstruct the lower orifice of the *ductus ad nasum*, and prevent the descent of the tears, which necessarily must return thro' the *puncta lachrymalia*; and sometimes they grow so enormously large, as even to alter the shape of the bones of the face.

When the *polypus* appears in the throat, it is always advisable to contract it that way; it being found, by experience, more ready to loosen when pulled in that direction, than by the nose. To this end, it would be right, before undertaking the operation, to let your patient lie supine two or three hours, which will bring it still farther down; for the body of the *polypus* does not universally adhere, and will by its weight stretch out the fibres by which it is connected to the nose; nay, there are instances, where by a little effort, such as hawking, they have dropt quite off.

The method of extracting it is by a pair of forceps, with a slit at their extremities for the better hold, which must be introduced into the nostril about an inch and a half, to make more sure of it towards the roots; then twisting them a little from one side to the other, you must continue in that action, while you pull very gradually the

body of the *polypus*. If it break, you must repeat the extraction as long as any remains, unless it is attended with a violent hæmorrhage, which is an accident that sometimes follows upon the operation, and seldom fails when the excrescence is scirrhous: However, the surgeon is not to be alarmed at the appearance of an immoderate effusion the moment after the separation; for, generally speaking, the vessels collapse very soon again; but if they do not, dry lint, or lint dipt in some styptic, will readily stop it.

After the extirpation, it has been usual, in order to prevent a relapse, to dress with escharotick powders, and even to burn with the actual cautery; but neither the one or the other can be of great service in this case, and both are painful and dangerous. If ever the use of corrosive medicines is advisable, it should be for destroying the remainder of a *polypus* which cannot all be taken away; and then the escharoticks may be better conveyed to the part by a long tent, than a seton passed through the nose and mouth, which is difficult to do without hurting the patient, and very nasty to bear.

Of the HARE LIP.

THIS disease is a fissure in the upper lip, with want of substance, and is a natural defect, the patient being always born with it, at least that species of hare-lip which requires the following operation. The cure is to be performed by the twisted suture. There are many lips, where the loss of substance is so great, that the edges of the fissure cannot be brought together, or at best where they can but just touch, in which case it need not be advised to forbear the attempt: it is likewise forbidden in infants, and with reason if they suck; but otherwise it may be undertaken with great safety, and even with more probability of success than in others that are older.

It is not uncommon for the roof of the mouth to be fissured likewise; but this is no objection to the operation, if the skin of the lip is loose enough to admit of re union: and it may be remarked, that the fissure of the palate, in length of years, closes surprisingly in some cases.

The manner of doing it is this. You first with a knife separate the lip from the upper jaw, by dividing the *frænum* between it and the gums; and if the *dentes incisivi* project, as is usual in infants, they must be cut out with the same knife; then with a thin pair of straight scissors take off the callous edges of the fissure the whole length of it, observing the rule of making the new wound in straight lines, because the sides of it can never be made to correspond without this caution. For instance, if the hare lip had the shape *a*, Plate CLVIII. fig. 5 the incision of the edges must be continued in straight lines till they meet in the manner represented by *b*, ibid. The two lips of the wound being brought exactly together, pass a couple of pins, one pretty near the top, and the other as near the bottom, through the middle of both edges of it, and secure them in that situation by twisting a piece of waxed thread cross and round the pins seven or eight times: you must then cut off the points, and lay a small bolster of plaster underneath them, to prevent their scratching; but when the lower part only of the hare lip can be brought into contact, it will not be proper to use more than one pin.

The pins are made three fourths of their lengths of silver, and the other part towards the point of steel; the silver pin is not quite so offensive to a wound as a brass or steel one; but

but a steel point is necessary for their easier penetration, which indeed makes them pass readily, that there is no need of any instrument to assist in pushing them through. The practice of bolting the cheeks forward does little or no service to the wound, and is very uneasy to the patient. The manner of dressing will be to remove the applications which are quite superfluous, as often only as is necessary for cleanliness. The method is to desist the three first days, and afterwards to do it every day, or every other day: it is not at all requisite to dress between the jaw and lip where the *frænum* was wounded, there being no danger that an inconvenient adhesion should ensue. In about eight or nine days the parts are usually united, and in children much sooner, when you must gently cut the threads, and draw out the pins, applying upon the orifices a piece of plaister and dry lint. It will be proper, in order to withdraw the pins more easily, to daub the ligatures and pins with warm water, and also moisten them with sweet oil, two or three days before you remove them, which will wash off the coagulated blood, that would otherwise fasten them so hard to the ligature as to make the extraction painful.

Of the WRY NECK.

THE operation of cutting the wry neck is very uncommon, and is never to be practised but when the disorder is owing to a contraction of the *massoideus* muscle only; as it can answer no purpose to set that muscle free by dividing it, (which is all that is to be done,) if the others in the neck are in the same state; and more especially if it has been of long standing from infancy; because the growth of the *vertebræ* will have been determined in that direction, and make it impossible to set the head upright.

When the case is fair, the operation is this. Having laid your patient on a table, make a transverse incision thro' the skin and fat, something broader than the muscle, and not above half an inch from the *clavicle*; then passing the probed razor with care underneath the muscle, draw it out and cut the muscle. The great vessels of the neck lie underneath; but when we are aware of their situation, the danger of wounding them may be avoided. After the incision is made, the wound is to be crammed with dry lint, and always dressed so as to prevent the extremities of the muscle from re-uniting; to which end they are to be separated from each other as much as possible by the assistance of a supporting bandage for the head, during the whole time of the cure, which will generally be about a month.

EXPLANATION OF Fig. 6. Plate CLVIII.

A. The instrument called the probe razor to cut the *massoideus* muscle in the wry neck, and is sharp only about half its length at that end where the blade is broad.

B. The two pins with the twisted suture, used in the hare-lip.

C. The *polypus* forceps, with one of the rings open for the reception of the thumb, which would be cramped in pulling the forceps with much force, if it were received in the same sort of ring as in the other handle.

Of the ANEURISM.

THIS is a disease of the arteries, in which, either by a preternatural weakness of any part of them, they become excessively dilated; or by a wound through their coats, the blood is extravasated amongst the adjacent cavities. The

first species of *aneurism* is incident to every part of the body, but does not often happen, except to the curvature of the *aorta*, which is subject to this disorder from the extraordinary impulse of the blood on that part: from the curvature, it runs upwards along the carotids or subclavians, generally increasing, till by its great distension it is ruptured, and the patient dies.

There are several histories given of *aneurisms* of the curvature of the *aorta*; in some of which, the vessel has been so excessively dilated, as to possess a great space of the upper part of the *thorax*; and the most curious circumstance to be gathered from them is, that the spot of the vessel which is weakest, and where the disease begins, generally gives way in such a manner to the force of the blood continually pushing it outwards, as to form a large pouch or cyst, with coats nearly as thick as those of the artery itself. However, the thickness of the coats of these cysts will last but to a certain period; for when the vessels of the coats can no longer conform to the extension, the circulation grows languid, the cyst becomes thinner at its apex, and soon after bursts.

The symptoms of this *aneurism*, are a strong pulsation against the *sternum* and ribs; every *syssole* of the heart; and, when it extends above the *sternum*, a tumour with pulsation. Upon dissection, the ribs, *sternum*, and *clavicle*, are sometimes found carious, from the obstruction of the vessels of the *periosteum*, which are pressed by the tumour.

What we have spoken of hitherto, has been only the *aneurism* of the *thorax* from an internal disorder; *aneurisms* of the extremities, are for the most part owing to wounds, though when they happen of themselves, they differ very little from the description given of that in the *thorax*. The further symptoms of them are (besides pulsation) the tumour's being without discolouration of the skin; its subsiding when pressed by the hand, and immediately returning when the hand is taken away; though, if it be upon the point of bursting, the skin will grow inflamed; and the coagulated blood in the cyst will sometimes make the pulsation much less perceptible.

This species of *aneurism* may sometimes be supported a great number of years, if we resist its dilatation by proper bandage; but if we do not, there is danger of its bursting, and, if it be pretty large, of rotting the adjacent bones.

A found artery wounded through part of its external coat would in all probability produce nearly the same appearances as where the whole coat is weakened from an internal indispotion; and this most likely is the case after bleeding in the arm, when it has not been immediately perceived that the artery was pricked, and the tumour has begun to form some days after the puncture; though the common appearance of an *aneurism* from the wound of a lancet, is a discharge of blood first through the orifice of the skin, and, upon being stoppt from bleeding outwardly, an insinuation of it amongst all the muscles as far as it can spread, in the shoulder and arm: here, the arm grows livid from the *ecchymosis*, and the blood coagulating to the consistence of flesh, prevents any sensible pulsation. The cyst which arises near the orifice of the artery is formed by the cellular capsule enveloping the vessels of that part, and a portion of the *aponeurosis* of the biceps muscle, which admitting of some extravasated blood underneath it, become excessively thickened and expanded. These membranes must make the cyst, otherwise we could not, upon opening the tumour in the o-

peration, discover so readily the puncture; or if the coats of the artery made it, we could not separate it distinctly from the vessel, which would be always dilated above and below the cyst, as we see in other *aneurisms*.

There are some few instances of small *aneurisms* and punctures of the artery from bleeding, doing well by bandage; but they almost all require the operation at last, which is to be performed nearly in the same manner in every part; and supposing it in the bend of the arm, is to be done after the following method.

Having applied the tourniquet near the shoulder, and laid the arm in a convenient situation, make an incision on the inside of the *biceps* muscle, above and below the elbow a considerable length, which, being in the course of the artery, will discover it as soon as you have taken away the coagulated blood, which must be all removed with the fingers, the wound being dilated sufficiently for that purpose. If the orifice does not readily appear, let the tourniquet be loosened, and the effusion of blood will direct you to it; then carefully carrying a crooked needle with a ligature under it, tie the vessel just above the orifice; and passing the needle again, make a second ligature below it, to prevent the return of the blood, and leave the intermediate piece of the vessel to slough away without dividing it. To avoid wounding or tying the nerve in making the ligature, the artery may be cleared away from it first, and held up with a hook; but should the nerve be tied with the artery, no great inconvenience would ensue from it. After the operation, the arm must be laid easy, on a pillow in bed, and the wound be treated in the common method, keeping it in that posture a fortnight or three weeks, especially if it should swell much, and not digest kindly.

In doing this operation, it will be proper to have the amputating instruments ready, lest it should be impracticable to tie the artery; and even after having tied it, the arm must be carefully watched; and in case of a mortification, it may be taken off.

OF AMPUTATION.

A spreading mortification has been always esteemed the principal cause for amputation, that it is a fashion with writers to treat of the nature of a gangrene previous to the description of this operation. However, this operation is spoken of as frequently unsuccessful; and in length of time, its want of success has been so unquestionably confirmed by repeated experiments, that some of the most eminent practitioners make that very circumstance an exception to the operation, which so few years since was the great inducement; and the maxim is, never to extirpate till the mortification is absolutely stopped, and even advanced in its separation.

Gangrenes may be produced two ways; either by indispotion of body, or by accident in a healthful state: for as the life of a part depends upon the circulation of its fluids, whatever shall make the circulation cease, will inevitably occasion a gangrene. Thus a mere compress preventing the course of the blood, as effectually causes a mortification as any indispotion in the fluids or vessels.

It frequently happens in old age, that the arteries of the lower extremities ossify; which destroying their elasticity, must in consequence produce a gangrene in the toes first, and afterwards in the limb nearly as high as where the ossi-

fication terminates; so that in mortifications arising from this cause, we at once see why amputation, during their increase, is of so little service, unless performed above the ossification; but we have no way to judge where the ossification ends, but by the inference we make from the gangrene's stopping: Hence we may learn the propriety of our modern practice in this case.

If by any accident the limb has been injured to that violent degree as to begin to mortify, it will be no more fit to operate here till it stops, than in the other instance; because all parts that are mortified have had the disposition to become so, before the effect is produced: and cutting off a limb, half an inch above the absolute dead skin, is generally leaving a part behind, with the seeds of a mortification in it; so, unless we can be sure the vessels are not affected in the place of amputation, which will be hard to know but from the consequence, the operation will be useless.

Sometimes the fluids of the body are so vitiated, as to lose their proper nutritious qualities: and the limb becomes gangrened, not from any alteration in its vessels, but chiefly from its situation, which being at a great distance from the heart, will be more prone to feel the ill effects of a bad blood than any other part, as the circulation is more languid in the extremities; and it seems not very improbable, that in some dispositions of the blood, a mortification may also be a kind of critical discharge. When therefore a gangrene arising from either of these causes, is running on, amputation above it will for the most part be useless: since it is only removing one degree of the effects of the bad juices, and leaving them in the same state to produce the like mischief in other parts. Thus we see, after amputations on this account, the gangrene sometimes falls on the bowels, or the other extremities: from which observation we may conclude it not safe to amputate, till the fluids are altered, and this alteration will presently discover itself by the stopping of the mortification.

Gunshot wounds, compound fractures, and all sudden accidents requiring amputation, are attended with the best success if immediately performed. Disorders of the joints, ulcers of long standing, and all scrophulous tumours, do sometimes return on other parts after the operation. When a leg is to be amputated, the manner of doing it is this.

Lay your patient on a table two feet six inches high, which is much better than a low seat, both for securing him steady, and giving yourself the advantage of operating without stooping, which is not only painful, but inconvenient in the other situation. While one of the assistants holds the leg, you must roll a slip of fine rag half an inch broad, three or four times round it, about four or five inches below the inferior extremity of the *patella*: This being pinned on, is to serve as a guide for the knife, which without it perhaps would not be directed so dexterously: The manner of rolling has always been perpendicular to the length of the leg; but having sometimes observed, that though the amputation at first be even, yet afterwards the *gastrocnemius* muscle contracting, draws back the inferior part of the stump more strongly than the other muscles: can do the rest of it; in order to preserve the regularity of the cicatrix, allow for this excess of contraction and make the circular incision in such a manner that the part of the wound

wound which is on the calf of the leg is a little farther from the hain than that on the skin is from the middle of the *patella*.

In the mean time, one of your assistants must carry a strong ligature round the thigh, about three or four inches above the *patella*, which passing through a couple of slits in a square piece of leather, he must twist with a tourniquet, till the artery is sufficiently compressed, to prevent any great effusion of blood; and to do it more effectually, he may lay a bolster of tow or linen under the ligature, upon that part where the artery creeps. It will also be a little more easy to the patient, to carry a compress of linen three or four times double, round the thigh, on that part where the ligature is applied, in order to prevent it from cutting the skin.

The course of the blood being stopped, you must begin your incision just below the linen roller, on the under part of the limb, bringing your knife towards you, which at one sweep may cut more than the semicircle; then beginning your second wound on the upper part, it must be continued from the one extremity to the other of the first wound, making them but one line. These incisions must be made quite through the *membrana adiposa*, as far as the muscles; then taking off the linen roller, and an assistant drawing back the skin as far as it will go, you make your wound from the edges of it when drawn back, through the flesh to the bone, in the same manner as you did through the skin. Before you saw the bones, you must cut the ligament between them, with the point of your knife; and the assistant who holds the leg while it is sawing, must observe not to lift it upwards, which would clog the instrument; and at the same time, not to let it drop. lest the weight of the limb should fracture the bone, before it is quite sawed thro'.

In amputating below the knee, it is of advantage to stand on the inside of the leg; because the *tibia* and *fibula* lie in a position to be sawed at the same time, if the instrument be applied externally: whereas, if we lay it on the inside of the leg, the *tibia* will be divided first, and the *fibula* afterwards; which not only lengthens the operation, but is also apt to splinter the *fibula* when it is almost sawed thro', unless the assistant be very careful in supporting it.

When the leg is taken off, the next regard is to be had to the stopping the blood; which must be effectually done before the patient is put to bed, or there will be great danger of bleeding again, when the fever is excited, and the vessels of the stump dilated, both which happen a very little while after the operation. There is no method for this purpose so secure, as taking up the extremities of the vessels with a needle and ligature in the following manner. As soon as the amputation is performed, the assistant must loosen the tourniquet for a moment, upon which the orifices of the arteries will appear by the issue of the blood. The operator having then fixed his eye upon one of the largest vessels, passes a crooked needle through the flesh, a little more than a quarter of an inch above the orifice, and about the same depth, in such a direction as to make nearly one third of a circle round the vessel: then withdrawing the needle, he a second time passes it into the flesh and out again, in the same manner and about the same distance below the orifice of the vessel. By this means, the thread will almost encircle the vessel, and when it is tied (which should be done by the surgeon's knot) will necessarily inclose it within the stricture. All the considerable arteries are to be

taken up in the same manner; that is, the tourniquet is to be loosened in order to discover the vessel, and then the needle is to be passed round. This is a much better way than using the artery forceps, where the vessels are apt to slip away out of the ligature: and as to styptic applications, their want of safety is so well known, that the use of them, in hemorrhages from large vessels, is almost universally rejected; though it is thought by several surgeons who have experienced the virtue of argic, that it will be found to be a more powerful astringent than any hitherto discovered.

It sometimes happens in a large stump, that ten or more vessels require tying; which done, you must apply loose dry lint to the wound; or in case the small vessels bleed plentifully, you may throw a handful of flour amongst the lint, which will contribute to the more effectual stopping up their orifices. Before you lay on the pledget, you must bind the stump, and begin to roll from the lower part of the thigh down to the extremity of the stump. The use of this roller is to keep the skin forwards, which, notwithstanding the steps already taken to prevent its falling back, would in some measure do so, unless sustained in this manner. The dressing may be secured by the cross cloth and gentle bandage; and the method of treating the wound may be learnt from what has been said with respect to recent incised wounds.

In amputating the thigh, the first incision is to be made a little more than two inches above the middle of the *patella*. After the operation, a roller should be carried round the body, and down the thigh, to support the skin and flesh: this is also the most proper bandage, as abscesses will sometimes form in the upper part of the thigh, which cannot discharge themselves so conveniently with any other, it being almost impracticable to roll above the abscess, unless we begin from the body.

The amputation of the arm or cubit differs so little from the foregoing operations, that it will be but a repetition to describe it. However, it must be laid down as a rule, to preserve as much of the limb as possible, and, in all amputations of the upper limbs, to place your patient in a chair.

The amputation of the fingers and toes is better performed in their articulation, than by any of the other methods: for this purpose, a straight knife must be used, and the incision of the skin be made not exactly upon the joint, but a little towards the extremity of the fingers, that more of it may be preserved for the easier healing afterwards: it will also facilitate the separation in the joint, when you cut the finger from the *metacarpal* bone, to make two small longitudinal incisions on each side of it first. In these amputations, there is generally a vessel or two that require tying, and which often prove troublesome when the ligature is omitted.

It may happen that the bones of the toes, and part only of the *metatarsal* bones, are carious; in which case, the leg need not be cut off, but only so much of the foot as is disordered: a small spring-saw is better to divide with here, than a large one. When this operation is performed, the heel and remainder of the foot will be of great service, and the wound heal up safely.

EXPLANATION OF FIG. 7. Plate CLVIII.

A. The figure of the amputating knife. The length of the blade and handle should be about thirteen inches.

B. The figure of the saw used in amputating the limbs. The length of the handle and saw should be about seventeen inches.

OF LUXATIONS.

A BONE is said to be luxated or dislocated, when it is moved out of its place or articulation, so as to impede its proper motion and office.

LUXATION of the Nose.

It sometimes happens, that the bones of the nose are separated from each other, or distorted out of their natural places, by some violent blow or fall. When such an accident happens, it is several ways discovered: as, (1.) By the sight, when we behold the deformed position of the nose; or, (2.) By feeling; or lastly, (3.) By the ear, when perceive with much difficulty the patient draws his breath through his nostrils.

When this case happens, the patient is to be speedily placed in a high chair, that an assistant may stand behind and hold his head firm, in a proper posture: the surgeon is then to introduce with one hand, a thick probe, a goose-quill, or little stick shaped for the purpose, up the nostril internally, by which means the depressed parts of the nose may be thrust into their places: in the mean time he applies his other hand externally, to guide and direct the parts which are moved from within: this being done, there is scarce any thing else required but to let a bit of sticking plaster lie upon the nose at the same time.

Of a DISLOCATION of the LOWER JAW.

THE lower jaw is indeed seldom luxated, because it is held so firm by strong ligaments and muscles, by whose assistance it is retained in two sinuses in the basis of the *cranium*: but when it is by accident forced out from thence, it may chance to be on one side only, or else on both, it being then thrust directly forwards: and this happens most frequently from opening the mouth too wide in yawning; though it has sometimes been occasioned by a violent blow or fall. If it be luxated on both sides, the chin will incline downward, and the jaw will be thrust very forward: but if only on one side, the chin will be inclined toward the opposite side; the elapfed little head of the jaw not being capable of dislocation but foreward and inward; for the processes of the bones of the *cranium* prevent the jaw from being dislocated backwards.

The lower jaw is chiefly known to be luxated on one side, when the chin is distorted on the opposite side: for that part to which the chin inclines, is the sound; but that from whence it recedes, is the luxated one: the mouth in this case gapes wider than usual, so that the patient cannot shut it, nor eat with his teeth; the lower range of teeth being projected beyond, and on one side the upper: but when the jaw is luxated on both sides, then the mouth not only gapes wide and open, but the chin also hangs down, and is thrown directly forwards; so that the patient cannot shut his mouth, speak distinctly, or even swallow any thing without much difficulty.

When the jaw is out only on one side, and the case recent, the cure is usually not so very difficult; but when both heads are dislocated, and not presently restored to their places, it always occasions the worst of symptoms, as pains,

inflammations, convulsions, fevers, vomitings, and at length death itself.

When this kind of luxation happens, the patient is to be directly seated on a low stool, so that an assistant may hold his head firm back against his breast. Then the surgeon is to thrust his two thumbs as far back into the patient's mouth as he well can; but they are first wrapped round in a handkerchief, to prevent them from slipping or being hurt; and his other fingers are to be applied to the jaw externally: when he has got firm hold of the jaw, it is to be strongly pressed, first downwards, then backwards, and lastly upwards, but so as that they may be all done in one instant; by which means the elapfed heads of the jaw may be very easily shoved into their former cavities.

If the jaw be out on one side only, every thing must be done in the same manner: but the luxated side of the jaw must be forced more strongly downward and backward than the sound one.

Of LUXATIONS of the HEAD and SPINE.

THE luxations which happen in the *spine* and *vertebrae* of the back are generally imperfect ones. For it appears from an accurate consideration of the structure and articulation of these bones, that none of the *vertebrae* can be entirely displaced without being fractured, and also compressing or wounding the spinal marrow, which must produce danger of instant death. Even the imperfect luxations of these bones are very dangerous: which happen either between the two superior *vertebrae* of the neck and the head, or else between the rest of the *vertebrae*, when they are forced from each other.

Such as have a luxation between the head and upper *vertebra*, seldom escape being carried off by a speedy and sudden death: for in this case the tender *medulla* which joins immediately with the brain, and is lodged in the spine, the brain itself, and the nerves which arise beneath the *occiput*, are too much distended, compressed, or lacerated; the two condyloide processes of the *occiput* usually slip out of their glenoid sinus's in the first *vertebrae* of the neck, when a person falls headlong from a high place, from off a ladder, from on horseback, or when he receives a violent blow upon his neck: they dying very suddenly in this case, are vulgarly said to have *broke their neck*, though there is generally no more than a luxation: yet it sometimes happens that the *vertebrae* of the neck are really fractured. If life should remain after such a luxation, which very rarely happens, the patient's head is commonly distorted with his chin close down to his breast, so that he can neither swallow any thing, nor speak, nor even move any part that is below his neck: therefore, if speedy assistance be not had, death ensues, from the compressure or hurt of the *medulla*.

But to repulse this unwelcome messenger, the patient is to be immediately laid flat upon the ground or floor: then the surgeon kneeling down with his knees against the patient's shoulders, is to bring them together so as to contain the patient's neck between them: this done, he quickly lays hold of the patient's head with both his hands, and strongly pulling or extending it, he gently moves it from one side to the other; till he finds, by a noise, the natural posture of the neck, and the remission of the symptoms, that the dislocation is properly reduced: by this method the surgeon retains the patient firm between his knees, and per-

performs the extension and reduction between his hands.

It will be proper, in order to prevent a tumor, and restore the stretched ligaments of the neck to their former vigour, to bathe it with *eg. Hungar. sp. vin. camph.* or some other strengthening spirit applied warm, as also compresses dipped in the same: the patient should bleed, and rest gently for some days, till the neck be found sufficiently strong and well.

With respect to the rest of the *vertebræ* of the back, they are seldom moved quite out of their places, unless they are fractured, they being retained, for the greatest part, by adhering to the adjacent ligaments and muscles: therefore the luxations which happen among them are usually imperfect; no more being displaced than their two upper or lower processes, and they often but on one side; and this happens sometimes to one of the spinal *vertebræ*, and sometimes to more. But it is here to be briefly observed, that it is usual to include among the number of luxated *vertebræ*, that which is found firm, but intercepted by others which are not so: thus whenever the upper *vertebræ* of the loins from the last of the back, and lowermost *vertebræ* of the loins next the *os sacrum*, are luxated, we commonly say and reckon there are five *vertebræ* out of their places; when, strictly speaking, only the two outermost or the uppermost and lowermost of those *vertebræ* are disturbed, the three middle ones retaining their natural situation and connection.

The signs common to luxations in the *spina dorsæ* are chiefly the following: the back itself is found to be crooked or unequal, after the external violence has been inflicted; the patient can neither stand nor walk, and his whole body seems to be paralytic; the parts which are beneath the luxated *vertebræ* are nearly without all sense and motion; the excrements and urine cannot be discharged, or else they are, sometimes emitted involuntarily; the lower extremities grow dead by degrees; and, at length, death itself follows: but these symptoms vary in proportion to the degree of violence in the luxation.

Luxations of the spinal *vertebræ* are very difficult to reduce. The following seems to be the most suitable method of reducing luxations of the *vertebræ*: when the *apophyses* of the *vertebræ* are dislocated on both sides, the patient is to be laid leaning upon his belly over a cask, drum, or some other gibbous body; then two assistants are strongly to press down both the ends of the luxated spine, on each side; by which means the bones of the spine will be set free from each other, lifted or pushed up in the form of an arch, and so gradually extended. This done, the surgeon presses down the luxated *vertebræ*, and at the same time nimbly pushes the superior part of the body upwards: and by this means the luxated *vertebræ* are sometimes commodiously reduced into their right places; but, if success should not attend the first time, the method should be repeated two or three times more.

It seems proper, after the *vertebræ* are reduced, to bathe the spine with *sp. vin.* or to lay on compresses dipped in *sp. vin. camph.* Afterwards the patient is to be laid in a soft and even bed; bleeding, and bathing the weak parts with strengthening spirits, are to be used as there may be occasion.

Of Luxations of the Os Coccyx, and Ribs.

THE *os coccyx* may be thrust inwards by a violent fall or blow, and it is often pushed outwards in hard birth. When

this happens, it is usually attended with violent pain and inflammation about the lower part of the spine, abscesses form in the *interspinum rectum*, and the *fæces* are contipated or suppressed. To discover the luxation of this bone the more readily, we have recourse to the use of our hands and eyes, as well as to the knowledge of the forementioned symptoms: nor is the replacing this bone very difficult, if attempted by a careful and expert surgeon; for if it be thrust outwards, it must be depressed into its right place by the thumb, after which may be applied compresses dipped in warm wine, or its spirit, made broad above, and narrow below, to fill up the posterior *sinus* of the *netæ*; and these may be held on by the T bandage; but that part of this bandage which comes between the thighs should be slit, and placed so that the patient may go to stool without undoing the bandage, and to prevent the bone from being by that means displaced again.

When the *os coccyx* happens to be luxated inwards, the first finger is to be introduced into the *anus*. After it has had its nail cut and been dipped in oil, it must be thrust as far as possible, that it may the more readily drive out the depressed bone; the other fingers being applied externally, are to conduct the bone into its right posture: when this has been done, it will be proper for the patient to rest some time upon the bed; and when he sits up, it should be in a chair with a hole in its bottom, lest the affected part should be otherwise compressed or disturbed.

The ribs are indeed sometimes, though but seldom, dislocated; for upon the assault of some external violence, it is not uncommon for them to be displaced either upwards, downwards, inwards, or outwards. They cannot be easily luxated outwards, because prevented by the vertebral processes, and resisted by very thick and strong muscles: but when they are drove into the cavity of the *thorax*, they not only lacerate the *pleura*, but do generally great injury to the contained parts; in consequence whereof arise most sharp pains, inflammations, difficulty of breathing, cough, ulcers, immobility, and many other dangerous symptoms of the like nature.

When the rib is dislocated either upwards or downwards, in order to replace it conveniently, the patient is to be laid on his belly upon a table, and the surgeon must strive to reduce the luxated rib into its right place with his hands; or, the arm of the disordered side may be suspended over a gate or ladder, and while the ribs are thus stretched up from each other, the heads of such as are luxated may be pushed into their former seat.

But those luxations wherein the heads of the ribs are forced into the *thorax*, are generally found to be much the most difficult to reduce; since neither the hand, nor any other instrument, can be applied internally to direct the luxated heads of the ribs: in this case it seems proper to lay the patient on his belly over some gibbous or cylindric body, and to move the fore-part of the rib inwards towards the back, shaking it sometimes; for thus generally the head of the luxated ribs slips into its former place: but if this method of cure will avail nothing, and the deplorable condition of the patient requires speedy help, we have no remedy left but incision, and endeavouring to replace the luxated head of the rib with the fingers, pliers, or little hooks. In the mean time, where the symptoms are not very urgent, and the heads of the ribs but little displaced, it is advisable neither to cut the flesh, nor violently force the ribs; be-

caufe there are feveral inftances where the luxated ribs have retained their diflocated ftations without any hurt: but above all, care muft be taken to lay on a comprefs dipped in warm *Sp. Vin.* or *Sp. Vin. Camph.*

The clavicles may be diflocated either from the top of the *fternum*, or *proceffus acromion* of the *fcapula*, by fome external violence, as a fall, blow, the lifting fome great weight, or the like.

Of a LUXATION of the HUMERUS.

THE *humerus*, from the length and laxity of its ligaments, the largeness of its motion, and the shallowness of the cavity in the *fcapula*, in'o which it is articulated, is thereby rendered of all bones the moft fubject to luxation. The head of this bone may often be diflocated under the arm pit, fometimes forwards, fometimes backwards, and even below the *fcapula*; but feldom perpendicularly downwards, and never directly upwards unlefs the *acromion* and *coracoid* proceffes of the *fcapula* fhould chance to be fractured at the fame time: befides, as long as the ftrong *deltoid* and *bicipital* mufcles of the *humerus* remain entire, they greatly refift and keep down the *humerus* from being luxated upwards.

When the *humerus* is luxated downwards, (1.) There fuddenly appears a cavity, and upon preffing with the fingers you will perceive a *finus*; but under the arm there muft be a tumour, becaufe the head of the bone is thruft there. (2.) The *proceffus acromion* will feem to flick out further than ufual, becaufe of the adjacent *finus*. (3.) The Luxated arm will be longer than the other, and it cannot be lifted up towards the head without violent pain, and fometimes it cannot be lifted up at all, or even extended. But when the *humerus* is luxated forwards as well as downwards, there will be obferved the fame *finus* under the *proceffus acromion* as before, and a tumour will appear from the head of the *humerus* projecting towards the breaft, under the *axilla*: the arm itfelf alfo cannot be moved without exciting the moft acute pain. Laftly, When the *humerus* is luxated backwards, the *cubitus* is thrown forwards towards the *præcordia*, and the head of the bone makes a protuberance in the fhoulder; the arm itfelf cannot be bent nor extended, nor even pulled outwards from the breaft, without occafioning the moft violent pains: but no luxation of this limb is attended with fuch dangerous fymptoms, as when it is diflocated forwards or inwards; becaufe the luxated head of the *humerus* cannot avoid injuring the large arteries and nerves of the arm; in confequence of which, various fymptoms will arife.

As foon therefore as the luxation is difcovered in the *humerus*, the fafeft way will be to feat the patient on the floor, or on a low ftool. Two ftrong affiftants are to be placed on each fide the patient: one of which fhould fecure his body, and, if poffible, the *fcapula* too, that it may not give way to the extension; while the other lays firm hold of the luxated arm with both his hands, a little above the *cubitus*, gradually and ftrongly extending it. But before that extension be made, the furgeon himfelf fhould have a large napkin, of a fufficient length, tied at the ends, and hung about his neck fo that the knot may be behind; but the other part of the napkin muft hang over his breaft: then the patient's arm muft be put through the napkin up to the fhoulder, and the furgeon at the fame time lays hold of the head of the *humerus* with both his hands: this done, he

orders the affiftant to extend the limb fufficiently, and in the mean time he himfelf elevates the head of the patient's *humerus* by the napkin about his neck, directing it with his hands, till it flip into its former cavity in the *fcapula*.

Of a LUXATION of the CUBITUS.

THE *cubitus*, confifting of two bones, the *ulna* and the *radius*, is articulated by *ginglymus*. The connection of thefe bones is fuch, that the *ulna* or *cubitus*, as being the largeft bone, and feated in the inferior part of the arm, does of itfelf perform the whole flexion and extension of the arm; yet it cannot perform that motion without carrying the *radius* along with it; fo that the *radius* always follows the *ulna* in flexion and extension: but, on the other hand, the *radius* may be turned along with the hand both inward and outward, without at all moving or bending the *ulna*; as when the pronation and fupination of the hand is made thereby. Both thefe bones of the *cubitus* are fo articulated with the lower head of the *os humeri*, that large protuberances are received into deep cavities or grooves, and the whole invell'd and fattened with exceeding ftrong ligaments; fo that notwithstanding the *cubitus* may be luxated in all four direCTIONS, outward, inward, forward, and backward, yet it is but feldom that it fuffers a perfect or entire diflocation, unlefs the upper part of the *ulna*, called *olecranon*, be broken, or the ligaments of the *cubitus* much weakened, by fome very great external violence.

If the *cubitus* be luxated backward, which is the moft frequent of all others, then the arm becomes crooked and fhorter, and it cannot be extended. In the inward part of the bend of the arm, the head of the *humerus* may be obferved to flick out; in the back part of the fame, the head of the *ulna* or *olecranon* will be protuberant, and between both bones will appear a *finus* or cavity. But it very feldom happens that the *cubitus* is luxated forward, from the largeness of the *olecranon*: unlefs that be fractured at the fame time. But if this fhould happen, the head of the *humerus* will flick out behind, and that of the *cubitus* before; and there will be a cavity more or lefs in proportion to the degree of the luxation. When the *cubitus* is luxated externally, the protuberance appears on the outfide of the *cubitus*; and the contrary when luxated inwards. To conclude, unlefs the ligaments and mufcles of the *cubitus* are quite broken in two, it is fo far from being capable of fuffering a perfect diflocation, that no more can happen to it than a fubluxation, i. e. it can but recede but a very little way out of its right place: but whatever of this kind happens, the cafe may be very eafily underftood, by feeling and infpecting the part, if there be no tumor: but if the joint be much fwelled, it is very difficult to be difcovered.

Be the luxation, however, more or lefs, the patient muft be fpeedily placed in a chair; and both parts of the limb, the *humerus* and the *cubitus*, muft be extended in oppofite direCTIONS by two ftrong affiftants, till the mufcles are found pretty tight, with a free fpace between the bones: then the luxated bone muft be repai'd with the furgeon's bare hands, or together with bandages; and that the proceffes may fall into their *foffes*, the *cubitus* muft be afterwards fuddenly bent. But if the tendons and ligaments are fo violently ftretched, that they can fcarce perform their office, it will not be improper to anoint them well with emollient oils, ointments, or the fat of animals, or to apply emollient fomentations and cataplafms.

As soon as the reduction has been by these means effected, the articulation must be bound up with a proper bandage, and the arm is to be afterwards suspended in a napkin or sling about the neck: but care must be taken, that the bandage be not suffered to be on too long, nor the arm to be kept all the time still, without some gentle motion.

On LUXATIONS of the HAND, CARPUS, METACARPUS, and FINGERS.

NOTWITHSTANDING the hand is very accurately connected to the two preceding bones, and particularly to the *radius*, by means of the *carpus* and strong ligaments, yet it sometimes suffers luxation in all four directions; but it is generally not so easy to be luxated on either side, as forward or backward, because of the two processes of the *radius* and *ulna*, which guard it on each side. The hand is said to be *luxated forwards or inwards*, when it recedes from the muscles which bend the fingers; to be *luxated backward*, when it departs from the muscles which extend the fingers: much also in the same manner, the hand is judged to be *luxated outward*, when the *carpus* makes a tumor near the thumb, and a cavity near the little finger; to be *luxated inward*, when the contrary happens.

It seems to be the safest way immediately to reduce what is displaced; and that this may succeed the better, two things are to be chiefly regarded: (1.) That the luxated hand be sufficiently extended by two assistants, one of which is to lay hold of the hand, and the other of the *humerus*, pulling in opposite directions: (2.) That the part of the extended hand, where the *sinus* is, be placed on a table, or some other flat body, that whatever sticks up may be depressed: by which method the hand, in whatever part luxated, may be very readily reduced into its natural seat.

It also sometimes happens, that one or two of the eight little bones of the *carpus* are luxated and distoed from their natural seat by some external violence. When this happens, there will be perceived a tumor in one part, and a cavity in another, which may be also felt by the fingers; besides, violent pains will be felt by the patient. For the rest, as this kind of luxation is very easily discovered, partly by the sight, and partly also by feeling: so, when it is recent, it is almost as readily cured, letting the hand be extended in the manner we before proposed, and the dislocated bone be afterwards forced into its place.

The four small bones, which are found in the *metacarpus* or palm of the hand, may be sometimes luxated from the *carpus* itself to which their upper parts are connected; which usually happens from some external violence. The two bones which are seated in the middle between the two other external ones, cannot be dislocated to either side; as the two external ones which sustain the first and little fingers cannot be luxated inwardly, but are more easily driven outward: though each of them may be luxated on the fore or back part of the hand. But which ever of these happens, the particular disorder may be discovered and examined by feeling and inspecting, and the cure may be carried on in altogether the same method which we directed before.

Lastly, The bones of the fingers, to which we join those of the thumbs, are liable to luxation at each of their articulations, and that in several directions. But these accidents, if recent, are both very easy to discover and cure: for the ligaments being not very robust, the tendons and muscles thin, and the *joints* of the articulations shallow, ren-

der the extension very easy, and the reduction of them into their former places may be done very readily. While one hand of the surgeon extends the finger, he strives with his other to replace the bones in their natural seat.

Of a LUXATION of the THIGH.

VERY rare is it that the head of the thigh-bone is displaced out of its *acetabulum*; though formerly it was supposed to be pretty frequent, physicians taking a fracture thereof for a luxation, the reason whereof may be taken from the articulation itself: (1.) How very deep is the *sinus*, called by the ancients *sinus coxae*, and by the moderns *acetabulum*, into which the head of the thigh-bone is received. (2.) With what a broad concave cartilage is almost the whole head of that bone covered. (3.) How strong are the ligaments with which it is fastened. (4.) How greatly it is defended with exceeding stout and thick muscles. (5.) But how very brittle is the neck of this bone beyond any other part thereof: from all which it appears, that the neck must be far more frequently and easily broke, especially in adults, than its head dislocated; and though something of this kind may sometimes happen, so as to make the head of the thigh-bone slip out of its *acetabulum*; yet that generally proceeds more from internal than external causes: for we find it has been observed by very skilful physicians, that the ligaments of the thigh bone, though very strong, may be by various causes, and particularly by a flux of humours, so relaxed and weakened, as to let the head of that bone slip spontaneously out of its *acetabulum*; so that it should seem no great wonder if the thigh should be sometimes luxated even while the patient lies in bed, without any external violence, so that when they rise, one leg appears longer or shorter than the other, and seems as if it were unhinged.

But this case does not happen so easy in robust adults, as in such as are more young and tender.

Whenever the said head of the thigh-bone is thrust out, it is almost always wholly displaced, so as to make a perfect luxation. The exact roundness of this head, with the great force of the circumjacent muscles, and the narrowness of the sides of the *acetabulum*, will not admit the bone to be dislocated a little way only; for as soon as the head of this bone is thrust up to the edge of the *acetabulum*, it must unavoidably either turn quite out, or else fall back again into its right place.

The thigh is usually luxated four ways; *upward, downward, backward, and forward*; but it is most frequently dislocated downwards and inwards, towards the large *foramen* in the *os pubis*: for besides that the cartilaginous defence on the lower part of the *acetabulum* is not so high as the rest, the *ligamentum rotundum* is found to give way more easily in that part than any other: and lastly, the adjacent muscles are found to be weakest in their resistance on this part, being insufficient to keep the head of this bone from slipping out; and then there is a certain eminence in this edge of the *acetabulum*, which keeps the head of the *os femoris* from falling back again into its right place: but if the head of this bone be displaced outwards, it generally slips upwards at the same time; it being scarce possible but the very strong muscles of the thigh must then draw the bone upwards, and then there is no eminence there, in the edge of the *acetabulum*, to resist the head of the bone in that passage; but should it at any time be luxated by an external

ternal force, there must certainly be a rupture of the round ligament.

When the thigh is dislocated forwards and downwards, which is what usually happens, the leg hangs straddling outward, and is longer than the other; also the knee and foot turn outwards; the head of the bone itself will be felt near the lower part of the *inguen* and *os pubis*: sometimes there is a suppression of urine in this case; when some nerve, which communicates with the bladder, is violently compressed; in the buttock may be perceived a cavity, from the *trochanter major* and the rest of the bone being displaced; and if the thigh-bone be not timely replaced into its *acetabulum*, the whole limb withers shortly afterwards; and this is the reason why the patient can bear little or no stress upon that limb, but must always incline and throw the weight of his body upon the other.

But if the thigh-bone be displaced backward, it is usually drawn upward also at the same time: hence there will be perceived a cavity behind the *inguen*; but upon the haunch or buttock, a tumour; because the head and *trochanter* of this bone will be thrust there. The tumour in the haunch being thrust upwards, the rest of the limb will become shorter than the other, and the foot will seem to turn inwards; the heel will not touch the ground, and so the person will seem to stand upon his toes; and lastly, the luxated limb may be bent with more ease than extended.

We do not without reason judge the thigh to be luxated, (1.) When we find the ligaments of the bone have been relaxed by some preceding congestion of humours, and when no external violence has been exerted upon it, especially in young patients. (2.) When neither the symptoms, pain, tumour, or inflammation follow: and lastly, (3.) When the whole limb may be bent and turned about at the *acetabulum* without any crushing of the bones, which is otherwise common in fractures. The contrary of these signs are strong indications that a fracture is present; more particularly if the foot in grown persons be shorter, from the injury of any external violence, and you hear a grating of the bones in moving the limb.

The luxated bone is always to be replaced in a method agreeable to the nature and direction of the dislocation. When it is displaced forwards and downwards, the patient is to be laid flat upon his back on a table; then a linen napkin or strong sling is to be made fast over the groin about the part affected, so that one end of the sling may come over the belly, and the other over the *nates* and back, to be both tied together in a knot upon the spine of the *os ilium*, and afterwards fastened to a hook fixed in some post, or held firm by some assistants; rather the first, if we use the polyspaston or pulley, to retain the patient's body firm from giving way in the extension; in like manner, at the bottom of the thigh, a little above the knee, there must be also fastened another napkin, or sling, with a compress between it and the thigh. Both the slings being drawn tight, the thigh is to be extended, not vehemently, but only so much as is sufficient to draw the bone out of its sinus, that it may be replaced into its *acetabulum* by the surgeon's hands; one hand is to press the head of the thigh-bone outward, while the other conducts the knee inwards; or, the reduction may be made by napkins, fastened round the extremities of the thigh like slings, much as in a luxation of the humerus: which will be more likely to succeed if the knee be at the same time pressed in-

wards by the hands. When the fore-recited means are not sufficient to make the extension, it will be necessary to make use of the polyspaston or pulley. As soon as the thigh is found to be sufficiently extended, the surgeon must take particular care to restore the luxated head of the thigh-bone with his hands from the *os pubis* into its former seat.

Whenever the thigh is luxated backward, the patient is to be placed flat on a table, with his face downward; and the thigh is to be extended in directly the same manner, but a little more strongly than we just now proposed; and the reduction is to be effected afterwards by the surgeon's hands, an assistant in the mean time extending the limb, and turning it inwards; by this means the head of the thigh-bone generally slips very readily again into its *acetabulum*.

Of a LUXATION of the PATELLA and KNEE, or TIBIA and FIBULA.

The *patella* is usually luxated mostly on the internal or external side of the joint; but whenever the knee is perfectly luxated, the *patella* can scarce avoid being displaced at the same time, because of its strong connection to the thigh and *tibia*.

The reduction of a luxated *patella* is usually no very great difficulty, if the patient be laid flat on his back upon a table or bed, or if he be laid in that posture upon an even floor, so as that the leg may be pulled out straight by an assistant: for then the surgeon may firmly grasp the *patella* with his fingers, and afterwards press it strongly into its right place; which may be also effected if the patient stands upright: when this is done, there remains nothing but carefully to bind up the disordered parts, and to let the patient rest quietly for some days, sometimes gently bending and extending his leg to prevent it from growing stiff, till the pains are gone off, and the limb has recovered its former strength.

A luxation of the knee is properly so, when the *tibia* recedes from under the *femur*. The leg is sometimes luxated from the basis of the thigh-bone, either on the out or inside, or backwards; seldom or never forwards, unless it be forced and driven very violently that way; because forwards, the *patella* is bound against the articulation, by the very strong tendons of the muscles which extend the leg; nor is it easy for the bones of the leg to be wholly displaced from that of the thigh, so as to make a perfect luxation; by reason of the great strength of the ligaments, and the two deep *sinuses* which receive the head of the thigh-bone.

As this kind of luxation is very easy to discover from the thin covering of the joint, with the tumors and cavities which follow; so, when it is discovered, it is as difficult to make a perfect cure thereof, without letting the bones join together; or leaving some stiffness in the knee; which first accident is usually called an *anchylosis*.

When the knee is but slightly luxated, the patient is to be seated on a bed, bench, or table, and one assistant holds the thigh firm above the knee, and the other extends the leg; but the surgeon in the mean time replaces the bones by his hands and slings if necessary, or pushes it by the application of his knee into its natural place.

Sometimes the *fibula* is separated by some external violence from the thigh-bone, and is then distorted either upward or downward: and this generally happens, when the foot has been luxated outward; therefore, when this is the case, there is need of extension. The bone is to be restored

Fig. 1.

restored to its natural place, and then properly bound up.

Of a Luxation of the Foot and Ankle.

THE ankle may be sometimes luxated either in jumping, running, or walking; and that in all four directions, inward, outward, backward, and forward. Which of these ways it happens to be luxated, may be discovered by the particular posture of the joint.

The ankle is more or less difficult to reduce in proportion to the violence of the cause by which it is luxated. But the most ready way of reducing a luxation of the ankle is to place the patient upon a bed, seat, or table, letting the leg and foot be extended in opposite directions by two assistants, while the surgeon strives to reduce the ankle with his hands and fingers. When the foot is by this means once replaced, it is proper to bind it up carefully, after it has been well bathed with *oxyerate* and salt, advising the patient to keep to his bed a good while, till the disorder and its symptoms quite leave him.

S U S

SURIANA, in botany, a genus of the decandria pentagynia class. The calix consists of six leaves, and the corolla of five petals; and there are five roundish seeds. There is but one species, a native of America.

URINAM, the capital of the Dutch settlements in Guiana, in South America: W. long. 56°, and N. lat. 6° 30'.

SURMOUNTED, in heraldry, is when one figure is laid over another. As the pile surmounted of a chevron in Plate CXLVII. fig. 17.

SURREPTITIOUS. See **SUBREPTITIOUS**.

SURRY, a county of England, bounded by the river Thames, which separates it from Middlesex, on the north; by Kent, on the east; by Sussex, on the south; and by Berkshire, on the west; being thirty-four miles long, and twenty-one broad.

SURROGATE, in law, denotes a person that is substituted, or appointed in the room of another.

SURSOLID, in arithmetick and algebra, the fifth power, or fourth multiplication of any number or quantity considered as a root. See **ARITHMETICK** and **ALGEBRA**.

SURVEYING, the art or act of measuring land; that is, of taking the dimensions of any tract of ground, laying down the same in a map or draught, and finding the content or area thereof. See **GEOMETRY**, p. 699.

SURVEYOR, a person who hath the oversight and care of considerable works, lands, or the like.

SURVEYOR likewise denotes a gauger; as also a person who surveys lands, and makes maps of them.

SURVIVOR, in law, signifies the longest liver of joint-tenants, or of any two persons jointly interested in a thing.

SUS, in zoology, a genus of quadrupeds belonging to the order of belluæ. They have four converging fore-teeth in the upper jaw, and six prominent ones in the under jaw: there are two short dog-teeth in the upper jaw, and one longer and jutting out in the under jaw; the snout is truncated, prominent, and moveable. There are five species. The *sus scrofa*, or common sow, is a native of the southern parts of Europe. It feeds coarsely, digs up roots, &c. from the ground with its snout. It is a

Sometimes it happens, that only the *os calcis* or *calcaneum* is luxated by some external force, and that either towards the internal or external side of the foot. Whichever way it happens, when there is pain and inequality of the member, that is, when it has a cavity in one part, and a tumour in another, there is strong reason to suppose a luxation: and as soon as it is discovered, the same method of cure is required with that before recited, keeping the limb quiet for some time afterwards.

Lastly, if any other bone in the foot, the *tarfus* or *metatarfus*, should happen to be luxated by some considerable external violence, the ligaments with the adjacent nerves and tendons are generally so affected as to excite not only most acute pains, but violent inflammations and convulsions; and even death itself has been observed to be the consequence, unless the bones were speedily replaced: it is therefore the safest way to reduce the luxations in these bones of the foot, by the method we before proposed for those of the hands, and that with the greatest expedition.

S W A

fat, sleepy, stupid, dirty animal, wallowing constantly in the mire. The sow brings forth a great number of young at a litter, and is therefore considered as a profitable animal. The flesh, however, is not reckoned to be of the most wholesome kind.

SUSDAL, a city of the province of Moscow, in Russia, one hundred miles north-east of Moscow.

SUSPENSION, or *Points of Suspension*, in mechanics, are those points in the axis or beam of a balance, wherein the weights are applied, or from which they are suspended. See **MECHANICS**.

SUSPENSION of Arms, in war, a short truce agreed on by both armies, in order to bury the dead, wait for fresh instructions, or the like.

SUSPENSION, in Scots law. See **LAW**, Tit. xxxii. 4.

SUSSEX, a county of England, bounded by Surrey and Kent on the north, by another part of Kent on the east, by the English channel on the south, and by Hampshire on the west: being sixty-five miles long, and twenty-nine broad.

SUTHERLAND, a shire of Scotland, bounded by Caithness on the north, by the German sea on the east, by Ross-shire on the south, and by the Caledonian ocean on the west and north-west.

SUTTON GOLEFIELD, a market-town twenty miles north-west of Warwick.

SUTURE, in anatomy. See **ANATOMY**, p. 152.

SUTURE, in surgery, a method of uniting the lips of wounds. See **SURGERY**, p. 650.

SWABBER, an inferior officer on board ships of war, whose employment it is to see that the decks are kept neat and clean.

SWABIA, a circle of the German empire, bounded by Franconia and the palatinate of the Rhine on the north, by Bavaria on the east, by Switzerland and Tyrol on the south, and by the river Rhine, which separates it from Alsatia, on the west; being one hundred and thirty miles long, and one hundred and ten broad.

SWALE, a river of Yorkshire, which rising on the confines of Westmorland, runs south-east through Yorkshire, and falls into the Ouse.

SWALLOW, in ornithology. See *HIRUNDO*.

SWALLOW-WORT, in botany. See *ASCLEPIAS*.

SWAN, in ornithology. See *ANAS*.

SWEAT, a sensible moisture issuing out of the pores of the skins of animals. See *PERSPIRATION*.

SWEDEN, one of the most northerly kingdoms of Europe, bounded by Norwegian Lapland on the north, by Russia on the east, by the Baltic sea on the south, and by Norway on the west; being upwards of eight hundred miles from north to south, and five hundred from east to west.

SWEEP, in the sea-language, is that part of the mould of a ship, where she begins to compass in at the rudder-heads: also, when the hawser is dragged along the bottom of the sea, to recover any thing that is sunk, they call this action sweeping for it.

SWEET, in the wine-trade, denotes any vegetable juice, whether obtained by means of sugar, raisins, or other foreign or domestic fruit, which is added to wines, with a design to improve them.

SWERIN, a town of lower Saxony, in Germany, capital of the duchy of Mecklenburg, and situated on the lake of Swerin; *E. long.* $11^{\circ} 30'$, and *N. lat.* 54° .

SWERTIA, in botany, a genus of the pentandria digynia class. The corolla is rotated, and there are nectariferous pores at the bases of the different laciniae of the corolla; the capsule has one cell, and two valves. There are five species, only one of them, *viz.* the perennis, or marsh gentian, a native of Britain.

SWIMMING, the art or act of sustaining the body in water, and of moving therein; in which action the air-bladder and fins of fishes bear a considerable part.

Though a great deal depends on the motion of the muscles of the several parts of the body, in the swimming of the fish; yet the tail, and those muscles which move the lower part of the body to which it is affixed, are the great instruments by which their swift motions in the water are performed. The moving the tail, and that part of the body to which it adheres, backward and forward, or sideways any one way, throws the whole body of the fish strongly the contrary way; and even in swimming straight forward, the motion and direction are both greatly assisted by the vibrations of this part, as may be experienced in the motion of a boat, which, when impelled forward, may be firmly guided by means of an oar held out at its stern, and moved in the water as occasion directs. The dorsal muscles, and those of the lower part of the body between the anus and tail, are the principal that are used in the motion of this part, and these are therefore the most useful to the fish in swimming. The muscles of the belly seem to have their principal use in the contracting the belly and the air-bladder. They have been supposed of use to move the belly-fins; but there are too many of them for such a purpose, and these fins have each its peculiar muscle fully sufficient to the business. The use of the tail in swimming is easily seen, by cutting it off, and committing the fish to the water without it, in which case it is a most helpless creature.

By the help of the tail they also turn about, by striking strongly with it on one side, and keeping it bent, so as to act like the rudder of a ship. The fins, especially the pectoral ones, serve to keep the fish upright, as also to ascend and descend.

Brutes swim naturally; but men attain this art by prac-

tice and industry. It consists principally in striking alternately with the hands and feet; which, like oars, row a person forward: he must keep his body a little oblique, that he may the more easily erect his head, and keep his mouth above water.

SWINE, in zoology. See *SUS*.

SWINGLING, the beating of flax or hemp. See *FLAX*. SWITZ, the capital of one of the cantons of Switzerland, to which it gives name, situated on the east side of the lake Lucerne, sixteen miles south-east of the city of Lucerne: *E. long.* $8^{\circ} 30'$, and *N. lat.* 47° .

SWITZERLAND, or SWISSERLAND, called Helvetia by the Romans, is surrounded by the territories of Germany, France, and Italy, being about two hundred and sixteen miles long, and upwards of one hundred miles broad.

SWORD, an offensive weapon, worn at the side, and serving either to cut or stab: its parts are the handle, guard, and blade; to which may be added the bow, scabbard, pommel, &c.

SWORD-FISH. See *XIPHIAS*.

SYCAMORE-TREE, in botany. See *ACER*.

SYCOPHANT, an appellation given by the ancient Athenians to those who informed of the exportation of figs, contrary to law; and hence it is still used in general for all informers, parasites, flatterers, cheats, &c.

SYLLABLE, in grammar, a part of a word, consisting of one or more letters, pronounced together.

SYLLABUS, in matters of literature, denotes a table of contents, or an index of the chief heads of a book or discourse.

SYLLOGISM, in logic, an argument or term of reasoning, consisting of three propositions; the two first of which are called premises, and the last the conclusion. See *LOGIC*, p. 991.

SYMBOL, a sign or representation of something moral, by the figures or properties of natural things.

Hence symbols are of various kinds, as hieroglyphics, types, enigmas, parables, fables, &c.

Among Christians, the term symbol denotes the Apostles' creed.

SYMMETRY, the just proportion of the several parts of any thing, so as to compose a beautiful whole.

SYMPATHETIC, something that acts, or is acted on, by sympathy: thus we say, sympathetic diseases, inks, powders, &c.

SYMPATHY, in medicine, denotes an indisposition befalling one part of the body, through the defect or disorder of another; whether it be from the influence of some humour, or vapour sent from elsewhere; or from the want of the influence of some matter necessary to its action.

SYMPHONY, in music, properly denotes a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony.

SYMPHYSIS, in anatomy. See *ANATOMY*, p. 148.

SYMPHYTUM, in botany, a genus of the pentandria monogynia class. The limbus of the corolla is tubular and somewhat ventricose, the fauces being closed with subulnated radii. There are three species, only one of them, *viz.* the officinale, or comfrey, a native of Britain. The root of the comfrey is a fine mucilage.

SYMPOSIARCH, in antiquity, the director, or manager of an entertainment. This office was sometimes performed by the person at whose charge the entertainment was provided;

- provided; sometimes by another named by him; and at other times, especially in entertainments provided at the common expence, he was elected by lot, or by the suffrages of the guests.
- SYMPTOM**, in medicine, any appearance in a disease, which serves to indicate or point out its cause, approach, duration, event, &c.
- SYMPTOMATICAL**, in medicine, is a term often used to denote the difference between the primary and secondary causes in diseases: thus a fever from pain is said to be symptomatical, because it rises from pain only.
- SYNÆRESIS**, contraction, in grammar, a figure whereby two syllables are united in one; as *vehemens* for *vehemens*.
- SYNAGOGUE**, a particular assembly of Jews met to perform the offices of their religion. Also the place wherein they meet.
- SYNALOEPHA**, in grammar, a contraction of syllables, performed principally by suppressing some vowel or diphthong at the end of a word, on account of another vowel or diphthong at the beginning of the next. As *ill' ego*, for *ille ego*, &c.
- SYNARTHROSIS**, in anatomy. See **ANATOMY**, p. 148.
- SYNCHONDROSIS**, in anatomy. See **ANATOMY**, p. 148.
- SYNCHRONISM**, denotes the happening of several things in the same time.
- SYNCOPATION**, in musick, denotes a striking or beating of time, whereby the distinction of the several times or parts of the measure is interrupted.
- SYNCOPE**, fainting, in medicine, a deep and sudden swooning, wherein the patient continues without any sensible heat, motion, sense, or respiration, and is seized with a cold sweat over the whole body, and all the parts turn pale and cold as if dead. See **MEDICINE**, p. 157.
- SYNCOPE**, in grammar, an elision or retrenchment of a letter or syllable out of the middle of a word, as *calvus* for *calidus*.
- SYNDIC**, in government and commerce, an officer in divers countries intrusted with the affairs of a city, or other community, who calls meetings, makes representations and solicitations to the ministry, magistracy, &c. according to the exigency of the case.
- SYNDROME**, a word introduced into medicine by the empirics, who mean by it a concurrence of symptoms.
- SYNECDOCHÊ**, in rhetoric, a kind of trope, frequent among orators and poets. There are three kinds of synecdochæ. By the first, a part is taken for the whole; as the point for the sword, the roof for the house, the sails for the ship, &c. By the second, the whole is used for a part. By the third, the matter whereof the thing is made is used for the thing itself; as steel for sword, silver for money, &c. To which may be added another kind, when the species is used for the genus, or the genus for the species.
- SYNECDOCHE**, in Greek and Latin grammar, is when the ablative of a part or an adjunct of a sentence is changed into the accusative.
- SYNCHRONESIS**, in grammar, a coalition whereby two syllables are pronounced as one.
- SYNGENESIS**, in botany. See **BOTANY**, p. 635.
- SYNNEUROSIS**, in anatomy. See **ANATOMY**, p. 148.
- SYNOCHUS**, or **SYNOCHA**, in medicine, a continual fever, without any remission. See **MEDICINE**, p. 79.
- SYNOD**, in astronomy, a conjunction, or concurrence of two or more stars, or planets, in the same optical place of the heavens.
- SYNOD**, signifies also a meeting, or assembly of ecclesiastical persons, concerning matters of religion.
- SYNODALS**, were pecuniary rents, commonly of two shillings, paid to the bishop, or archdeacon, at the time of their Easter visitation, by every parish priest.
- SYNODICAL**, something belonging to a synod: thus synodical epistles are circular letters written by the synods to the absent prelates and churches, or even those general ones directed to all the faithful, to inform them of what had passed in the synod.
- SYNOECIA**, in Grecian antiquity, a feast celebrated at Athens, in memory of Theleus's having united all the petty communities of Attica into one single commonwealth, the seat whereof was Athens, where all the assemblies were to be held. This feast was dedicated to Minerva; and, according to the scholiast of Thucydides, it was held in the month Metagion.
- SYNONYMOUS**, is applied to a word or term that has the same import or signification with another.
- SYNOVIA**, in medicine, a term used by Paracelsus, and his school, for the nutritious juice proper and peculiar to each part; thus they talk of the synovia of the joints, of the brain, &c.
- SYNTAX**, in grammar, the proper construction, or due disposition of the words of a language, into sentences, or phrases. See **GRAMMAR**.
- SYNTEXIS**, in medicine, an attenuation, or colligation of the solids of the body, such as frequently happens in atrophies, inflammations of the bowels.
- SYNTHETIC**, or **SYNTHETICAL**, is, according to Dr. Shaw, a term given to that part of chemistry, which, after the analytical chemistry has taken bodies to pieces, or reduced them to their principles, can, from these separated principles, either recompound the same body again, or, from the mixtures of the principles of one or more bodies in various manners, form a large set of new productions, which would have been unknown to the world, but for this art: such productions are brandy, soap, glass, and the like.
- SYNUSIASTS**, a sect of heretics, who maintained, that there was but one nature and one single substance in Jesus Christ.
- SYRACUSE**, a city and port-town of Sicily, in the province of Val de Noto, situated on a fine bay of the Mediterranean sea, on the east coast of the island: in E. long 15° 5', N. lat. 37° 25'.
- SYRIA**, a part of Asiatic Turkey, bounded by Natolia and Turcomania, on the north; by Diarbec or Mesopotamia on the east; by Arabia and Palestine on the south; and by the Levant-sea on the west. The Turks divide Syria into three beglerbeglies, or vice-royalties, viz. those of Aleppo, Tripoli, and Damascus, or Scham, the seats of the respective viceeroys.
- SYRINGA**, in botany, a genus of the diandria monogynia class. The corolla consists of four segments, and the capsule has two cells. There are two species, both natives of Persia.
- SYRINGE**, a well known instrument, serving to imbibe or suck in a quantity of fluid, and to squirt or expel the same with violence.
- A syringe is only a single pump, and the water ascends

in it on the same principle as in the common sucking pump. See *HYDROSTATICS*, p. 808.

SYRUP, in pharmacy, a saturated solution of sugar, made in vegetable decoctions, or infusions.

SYSSARCOSIS, in anatomy. See *ANATOMY*, p. 148.

SYSTEM, in general, denotes an assemblage or chain of principles and conclusions, or the whole of any doctrine, the several parts whereof are bound together and follow or depend on each other; in which sense we say, a system of philosophy, a system of divinity, &c.

SYSTOLE, in anatomy, the contraction of the heart, whereby the blood is drawn out of its ventricles into the arteries; the opposite state to which is called the diastole, or dilatation of the heart.

SYSTYLE, in architecture, that manner of placing columns where the space between the two fusts consist of two diameters, or four modules.

SYZYGY, in astronomy, a term equally used for the conjunction and opposition of a planet with the sun. See *ASTRONOMY*.

T.

T A B

TABAGO, one of the Caribbee islands in the American ocean, one hundred and twenty miles south of Barbadoes: W. long. 59°, N. lat. 11° 30'.

TABARCA, an island on the coast of Barbary, in Africa, fifty miles west of Tunis: E. long. 8°, N. lat. 36° 30'.

TABASCO, the capital of a province of the same name, situated on the bay of Campeachy, at the mouth of the river tabasco, one hundred and sixty miles south-west of Campeachy: W. long. 95°. N. lat. 18°.

TABBY, in commerce, a kind of rich silk which has undergone the operation of tabbying. See the next article.

TABBYING, the passing a silk or stuff under a calender, the rolls of which are made of iron or copper, variously engraven, which bearing unequally on the stuff renders the surface thereof unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLA, **TABLET**, in pharmacy, is much the same with troches and lozenges, being a solid preparation formed into a little cake, or mass, of different figures, intended to dissolve slowly, and generally made agreeable to the palate.

TABELLIO, in the Roman law, an officer or scrivener, much the same with our notaries-public, who are often called tabelliones in our ancient law-books.

TABERNACLE, among the Hebrews, a kind of building, in the form of a tent, set up, by express command of God, for the performance of religious worship, sacrifices, &c. during the journeying of the Israelites in the wilderness; and, after their settlement in the land of Canaan, made use of for the same purpose till the building of the temple of Jerusalem. It was divided into two parts, the one covered, and properly called the tabernacle; and the other open, called the court. The curtains which covered the tabernacle were made of linen, of several colours, embroidered. There were ten curtains, twenty-eight cubits long and four in breadth. Five curtains fastened together made up two coverings, which covered all the tabernacle. Over these there were two other coverings; the one of goat-hair, and the other of sheep-skins. The holy of holies was parted from the rest of the tabernacle by a curtain made fast to four pillars, standing ten cubits from the end. The length of

T A B

the whole tabernacle was thirty-two cubits, that is, about fifty feet; and the breadth twelve cubits, or nineteen feet. The court was a spot of ground one hundred cubits long, and fifty in breadth, inclosed by twenty columns, each twenty cubits high and ten in breadth, covered with silver, and standing on copper bases, five cubits distant from one another; between which, there were curtains drawn, and fastened with hooks. At the east end was an entrance, twenty cubits wide, covered with a curtain hanging loose.

Feast of TABERNACLES, a solemn festival of the Hebrews, observed after harvest, on the fifteenth day of the month Tisri, instituted to commemorate the goodness of God, who protected the Israelites in the wilderness, and made them dwell in booths, when they came out of Egypt. On the first day of the feast, they began to erect booths of the boughs of trees, and in these they were obliged to continue seven days. The booths were placed in the open air, and were not to be covered with cloths, nor made too close by the thickness of the boughs; but so loose that the sun and the stars might be seen, and the rain descend through them.

TABERNÆMONTANA, in botany, a genus of the pentandria monogynia class. It has two horizontal follicles; and the seeds are pulposus. There are three species, all natives of America.

TABES, or **CONSUMPTION**. See *MEDICINE*, p. 103.

TABLATURE, in musick, is, in general, when, to express the sounds or notes of a composition, we use the letters of the alphabet, or any other characters not used in the modern musick.

Laws of the twelve TABLES, were the first set of laws of the Romans, thus called, either by reason the Romans then wrote with a style on thin wooden tablets covered with wax; or rather, because they were engraven on tables, or plates of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans were then without any fixed or certain system of law, at least had none ample enough to take in the various cases that might fall between particular persons, it was resolved to adopt the best and wisest laws of the Greeks. One Hermodorus was first appointed

te translate them, and the decemviri afterwards compiled and reduced them into ten tables. After a world of care and application, they were at length enacted and confirmed by the senate and an assembly of the people, in the year of Rome 303. The following year they found something wanting therein, which they supplied from the laws of the former kings of Rome, and from certain customs which long use had authorised: all these being engraven on two other tables, made the laws of the twelve tables, so famous in the Roman jurisprudence, the source and foundation of the civil or Roman law.

TABLES of the law, in Jewish antiquity, two tables on which were written the decalogue, or ten commandments, given by God to Moses on Mount Sinai. See **DECA-LOGUE**.

TABLE, in mathematics, a system of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations.

Astronomical TABLES, are computations of the motions, places, and other phenomena of the planets.

TABORITES, a branch or sect of the ancient Hufites.

They carried the point of reformation farther than Hufs had done, rejected purgatory, auricular confession, the unction of baptism, transubstantiation, &c. They reduced the seven sacraments of the Romanists to four, viz. baptism, the eucharist, marriage, and ordination.

TABRISTAN, a province of Persia, situated on the northern shore of the Caspian sea, having the province of Astrabat on the east, and Gilan on the west; being part of the ancient Hyrcania.

TACAMAHACA, in pharmacy, a solid resin, improperly called a gum, in the shops: it is of a fragrant and peculiar smell, and is of two kinds; the one called the shell-tacamahaca, which is the finest; the other, which is an inferior kind, being termed rough-tacamahaca, or tacamahaca in grains.

Some greatly commend tacamahaca in disorders of the breast and lungs; but, at present it is very rarely used internally. Externally, however, it is in repute for softening tumours, and mitigating pain and aches.

TACK, in a ship, a great rope having a wale-knot at one end, which is seized or fastened into the clew of the sail; so is reefed first though the cheffe-trees, and then is brought through a hole in the ship's side. Its use is to carry forward the clew of the sail, and to make it stand close by a wind: and whenever the sails are thus trimmed, the main-tack, the fore-tack, and mizen-tack, are brought close by the board, and haled as much forward on as they can be.

TACK, in Scots law. See **LAW**, Tit. xiii. 8, &c.

TACK-ABOUT, in the sea-language, is to turn the ship about, or bring her head about, so as to lie the contrary way.

TACKLE, among sea-men, denotes all the ropes or cordage of a ship, used in managing the sails, &c.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions.

TADCASTER, a market-town of Yorkshire, ten miles south-west of York.

TADORNA, in ornithology. See **ANAS**.

TADPOLE, a young frog, before it has disengaged itself

from the membranes that envelope it in its first stage of life. See **RANA**.

TÆNIA, in zoology, a genus of insects, belonging to the order of vermes zoophyta; the body of which is of an oblong form, and composed of evident joints or articulations, in the manner of the links of a chain, with a mouth and viscera in each joint; so that the joints, which are exceedingly numerous, are in some measure so many distinct animals, and can live independent of each other. There are four species; the solium, or tape-worm, is found in the bowels of men, and fishes, and frequently extends to many yards in length. See **MEDICINE**, p. 160.

TÆNIA, in architecture, a member of the Doric capital resembling a square fillet, or reglet: it serves instead of a cymatium.

TAFFETY, in commerce, a fine smooth silken stuff, remarkably glossy.

TAGETES, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is naked; the papus has five straight awns; the calix consists of one tubulous leaf with five teeth; and there are five persistent floscules in the radius. The species are three, all natives of America.

TAGUS, the largest river of Spain; which, taking its rise on the confines of Arragon, runs south-west through the provinces of New Castile and Estremadura; and passing by the cities of Aranjuez, Toledo, and Alcantara, and then crossing Portugal, forms the harbour of Lisbon, at which city it is about three miles over; and about eight or ten miles below this, it falls into the Atlantic ocean.

TAJACU, in zoology, a species of hog. See **Sus**.

TAIL, the train of a beast, bird, or fish; which, in land animals, serves to drive away flees, &c. and in birds and fishes, to direct their course, and assist them in ascending or descending in the air or water.

TAILZIE, in Scots law. See **LAW**, Tit. xxviii. 8, &c.

TAINÉ, a port-town of Ross-shire, in Scotland, situated on the south-side of the frith of Sutherland, seven miles north of Cromarty: W. long. 3° 38', N. lat. 58°.

TALC, in natural history, a large class of fossil bodies, composed of broad, flat, and smooth laminæ or plates, laid evenly and regularly on one another; easily fissile, according to the site of these plates, but not all so in any other direction; flexible, and elastic; bright, shining, and transparent; not giving fire with steel, nor fermenting with acid menstrua, and sustaining the force of a violent fire without calcining.

TALENT, money of account among the ancients.

Among the Jews, a talent in weight was equal to 60 maneh, or 113 lb. 10 oz. 1 dwt. 10½ gr.

TALIO, *lex talionis*, a species of punishment in the Mosaic law, whereby an evil is returned similar to that committed against us by another; hence that expression, eye for eye, tooth for tooth.

TALISMANS, magical figures cut or engraved with superstitious observations on the characterisms and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences. The talismans of Samothrace, so famous of old, were pieces of iron formed into certain images, and set in rings; these were esteemed preserva-

tives against all kinds of evils. There were likewise talismans taken from vegetables, and others from minerals. **TALLOW**, in commerce, the fat of certain animals, melted down and clarified, so as to be fit for making candles, &c.

TALLOW-TREE, a remarkable tree growing in great plenty in China; so called, from its producing a substance like tallow, which serves for the same purpose: it is about the height of a cherry-tree, its leaves in form of a heart, of a deep shining red colour, and its bark very smooth. Its fruit is inclosed in a kind of pod, or cover, like a chestnut, and consists of three round white grains, of the size and form of a small nut, each having its peculiar capsule, and within a little stone. This stone is encompassed by a white pulp which has all the properties of true tallow, both as to consistence, colour, and even smell; and accordingly the Chinese make their candles of it; which would doubtless be as good as those in Europe, if they knew how to purify their vegetable, as well as we do our animal, tallow.

TALLY, a piece of wood cut in two parts, whereon accounts were anciently kept, by means of notches; one part of the tally being kept by the debtor, and the other by the creditor.

TALMUD, among the Jews, a collection of the doctrines of their religion and morality. It is the *corpus juris*, or body of the laws and customs of the Jews, who esteem it equal to the scriptures themselves.

TALPA, in zoology, a genus of quadrupeds belonging to the order of fereæ. There are six fore-teeth in the upper-jaw, and eight in the under-jaw; they have one large dog-tooth, and four smaller ones. There are two species, *viz.* the caudata, or common mole, with a tail, and five toes on the feet; it is a native of Europe, feeds upon worms, and, by raising the earth, infests gardens and cultivated grounds. This animal has a penis much longer, in proportion to the size of its body, than any other creature. The fur is exceedingly smooth and fine. Though generally believed to be blind, it has a couple of small eyes mostly hid with hair. 2. The *afatica* has no tail, and but three toes on its feet. It is a native of Siberia.

TAMANDAU, in zoology. See *MYRMECOPHAGA*.

TAMARINDUS, in botany, a genus of the triandria monogynia class. The calix consists of four segments, and the corolla of three petals; the nectarium consists of two short bristles under the filaments; and the pod is pulpy. There is but one species, a native of Ægypt, Arabia, &c.

The pod is made up of a double rind, or membrane, between which is a pulpy matter; which taken in the quantity of two or three drams, or an ounce or more, proves gently laxative or purgative; and at the same time,

by its acidity, quenches thirst, and allays immoderate heat.

TAMARIX, in botany, a genus of the pentandria trigynia class. The calix consists of five segments, and the corolla of five petals: the capsule has one cell, and three valves; and the seeds are pappous. There are two species, none of them natives of Britain.

The bark and leaves of the tamarix-tree are moderately astringent.

TAMBAC, a mixture of gold and copper, which the people of Siam hold more beautiful, and set a greater value on, than gold itself.

TAMUS, in botany, a genus of the diœcia hexandria class. The calix of both male and female consists of six segments; neither of them have any corolla; the stylus is trifid; and the berry has three cells, containing two seeds. There are two species, none of them natives of Britain.

TAMWORTH, a borough of Staffordshire, situated twenty miles south-east of Stafford. It sends two members to parliament.

TAN, the bark of the oak, chopped and ground in a tanning-mill into a coarse powder, to be used in the tanning of leather. See *TANNING*.

TANACETUM, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is naked; and the calix is hemispherical and imbricated. There are eight species, only one of them, *viz.* the vulgare, or common tansy, a native of Britain.

Tansy, considered as a medicine, is a moderately warm bitter, and is much extolled by some in hysteric complaints, especially if proceeding from a deficiency or suppression of the uterine purgations: its seeds and leaves have been in considerable esteem as anthelmintics; and are said to be good in colics and flatulencies.

TANGENT of an arch is a right-line drawn perpendicularly from the end of a diameter, passing to one extremity of the arch, and terminated by a right-line drawn from the centre through the other end of the arch, and called the secant. See *GEOMETRY*.

TANGIER, a port-town of Africa, in the empire of Morocco and kingdom of Fez, situated at the entrance of the straits of Gibraltar, in W. long. 7°, N. lat. 35° 40'. It was the capital of the ancient Mauritania Tingitana, and was once in the possession of the English.

TANGUT, a province of Chinese Tartary, situated north-west of the great wall which divides Tartary from China.

TANJOUR, a city of the hither India, capital of a province of the same name, situated E. long. 79°, N. lat. 11° 30'.

TANNER, one who dresses hides, &c. by tanning them. See the next article.

T A N N I N G.

TANNING is the art of preparing raw hides or skins for the hand of the currier; or for immediate use, without any further operation.

The first part of this definition includes all leather used

for the upper part of shoes, coaches, coach-harnes, saddler-leather, &c. and the last, the manufacture of bin or backs, &c.

We shall first give a general account of the process of manu-

manufacturing leather comprehended under the first part of the definition; and then explain separately the particular operations comprehended under the general process.

When the hide or skin is received raw from the hand of the butcher, it is thrown into a water-dub or other piece of water, to cleanse it from the blood and gore; after which, the horns and tail are cut off: then it is put into the lime, and wrought there according to the directions given below; from thence it is wrought into the bait, and cleansed there from the lime, &c. It is next transferred to the ooze; and when properly filled, according to the directions on that head, it is conveyed to the tann-pit, where it is tanned; which finishes the process.

Before we proceed, it will be necessary to give a short view of the nature and structure of leather, which will contribute to explain the reason of the different operations it passes through.

All hides or skins, when received from the hand of the butcher, are a bundle of connected tubes, somewhat resembling a honey-comb fixed on a basis; on the flesh-side, of an extreme close texture; but all open on the hair or grain side. These tubes contain a fatty or mucilaginous kind of matter; which, if allowed to remain in a fluid state, would corrupt the leather, and, if dried in the hide, would not only occasion a crisp or hardens in the leather, and be easily softened by moisture; but would also, in the course of tanning, in a great measure oppose every substance that can be applied to consolidate and preserve the hide from corruption.

To extract this matter; to swell and expand the pores as much as they can bear, without a disunion of parts, in order to increase the thickness, and the more easily to re-fill or introduce a matter less subject to changes from drought and moisture; to preserve the fibres that compose the leather from putrefaction; and to consolidate the whole into one durable mass; are the ends proposed by the several operations of tanning.

OF LIMING.

THE extraction of the matter contained in the pores being the first aim of the tanner, the first step is to open and expand the fibres, that the matter may be the more easily ejected, in order to give room for the subsequent reception of the tan. This is done by common slacked lime infused in water, and is made up in a pit built with stone, of a length sufficient to contain a midding hide, but seldom so broad as to allow it to lie at its full breadth. The hides are generally treated in the lime in the following manner. They are thrown into a lime-dub, of a weak or slack consistence at first; where they are drawn out and thrown in twice or thrice every day, for a few days. They are then conveyed to a lime of a stronger quality, and drawn as before, though perhaps not so often; once in a day, or once in two days when they are further advanced, may suffice. After they have lain there for ten or fourteen days, the strength of the lime may be increased, or they may be carried to one of a stronger nature, where they are drawn and returned as before till they be completely limed.

As the hastening and retarding the operation in particular cases may be necessary; and as it is material for the quality of the leather, that the lime should make an equal impression upon the hide; or rather, if possible, that the weaker parts should be saved, and the stronger more exposed; the following observation may be of use. In most yards there

are from 20 to 40 hides or upwards wrought in a lime at a time. When these hides are all thrown in, they must necessarily be made to lie spread out upon one another, as close as possible, to take up little room. By this means those that are near the bottom of the pit will be squeezed so closely together by the pressure of the superior hides, that the water, the medium by which the lime is communicated to them, will be almost entirely excluded from acting upon the body of the hide, while the bellies and other outer skirts will be exposed to its full force. For this reason, it is necessary to change their position often, that the different parts of the hides may have nearly the same opportunity of being impregnated with the lime: and in this view, since drawing in the limes is necessary, it is also evident, that no prejudice can accrue to the leather from the frequent repetition of it, but may be greatly hurt if it is neglected. The often drawing of leather must not only bring on the operation more equally, but must at the same time quicken the effect of the lime, as the exposure of the hide to the air and lime by turns will give it an opportunity of acting with greater force. Besides, the workman has it in his power, every time the dub is drawn, either to add new strength to it (if necessary) by giving more lime, or to make it exert the strength it already possesses by stirring or raising the lime from the bottom. Thus the workman has it greatly in his power to accelerate or retard the operation as he shall think proper. Small leather ought to be drawn oftener than large, as it is not so able to resist the strength of the lime. During very hot weather the lime will operate more quickly than in cold: therefore the workman ought to pay a strict attention to the state of his limes at that time, and draw oftener. The rays of the sun, if allowed to act any time on the leather when it is in the draught, will greatly hurt it.

From the above hints, the workman will be enabled to form some judgment how to vary his work according to the different circumstances that may occur. And here it would seem requisite, that some directions should be given for knowing when the leather is sufficiently limed. But it is impossible to convey ideas in an intelligible manner by words, which can only be acquired by practice and frequent observation. Only we may observe in general, as the hide becomes limed, it leaves the original raw fleshy appearance, has more of the appearance of being boiled, and becomes more plump and spongy. But all these appearances are the more visible in proportion as the leather is over-done; and therefore it would be extremely dangerous for a person without experience to trust to the above marks. However, though the time taken to perform this operation may be much varied; yet the ordinary time for a midding hide is from 4 to 6 weeks, and so in proportion for larger and smaller leather.

OF BAITING, and other work before Oozing.

THE hide is now stripped of its hair, and all the slimy fatty stuff separated from the leather that is found adhering to the flesh-side; the first of which operations is called hairing, and the last fleshing. After which, as it is the workman's aim to discharge the matter contained in the pores of the leather, as also the particles of lime that may have insinuated themselves during the liming; and as the lime will be found to have communicated a degree of elasticity to the fibres, and a tenacious quality to the matter; it is necessary to unbrace and relax the fibres, and bring the matter

to be ejected into a greater state of fluidity before we attempt to repel it. An infusion of hen or pigeon dung and water, (which is called a bait,) has been found to be the most effectual thing for answering the above end. Into this infusion the hides are thrown promiscuously, where they are drawn in the same manner as directed in the article of liming; and in proportion to the draughts given, the strength of the leather, trim of the bait, &c. the workman will find his point gained from 4 to 8 days: he will find the leather reduced to a soft mellow consistence without any corruption or decay of parts, the matter more fluid and less tenacious, and easily separable from the hide upon working it on the beam with the tanners knife: but as once working cannot purify the hide, the workman must soak it in water, and work it on the beam, alternately, such a number of times as his judgment shall direct, in order to purge it thoroughly; and as it was observed before, that all the pores of the leather were open on the grain-side, most of the work should be applied on that side. As a putrefaction or corruption of the parts, or an extension of the fibres beyond their proper tone, can never be remedied when once begun, the over-doing or undue management either in baiting or liming, must be equally fatal. To obtain the ends proposed by these two operations, and at the same time to guard against their bad effects, require more experience and knowledge in the nature of leather than any other operation it has afterwards to go through.

Of Oozing.

THE hide, when ready for the ooze, ought to be nothing but a bundle of empty tubes void of all fluid matter; that is, composed of nothing but what is called the solids of the hide, without any decay or corruption.

It is now the tanner's business to fill these tubes or pores with a more durable matter, in order to support the fabric of the leather; which is the end of oozing. A number of different substances have been tried for this purpose; but none are equal to oak-bark. This bark, after it is thoroughly dried, is pounded, or rather bruised with a mill or other instrument; the powder is sifted out for the purpose of making up oozes, which is only an infusion of this powder in common water; an old or exhausted ooze (if not begun to corrupt) may be renewed by adding more bark, according to the strength of the ooze required. This liquor is deposited in a number of handlers or dusters, (as they are called,) as occasion requires, and the hides are thrown promiscuously into it, where they must be drawn and returned much in the same manner as directed in the article of liming, and carried from a weaker to a stronger ooze as the leather shall require, till they are found to be sufficiently filled. It will be found, that the finer particles of the bark will insinuate themselves into the pores of the leather, and lodge there; and at same time the astringent quality will strengthen and brace the fibres, and bring them again to their proper tone, after their relaxed state in the bait, which will make the leather appear to swell, and feel plump and soft. Here again no rule can direct an unexperienced person to know when a hide is properly oozed; and indeed some kinds of leather require a greater and some a lesser degree of it, according to the purpose for which it is intended; but in general, there is less danger in oozing plentifully than in being sparing of it, as it always adds to the weight and beauty of the leather. A middling hide may be oozed in three weeks,

and sooner or later in proportion to the strength of the ooze, the number of draughts, and heat of the weather.

Of Lopping, or what is more properly called Tanning.

THIS part of the operation is designed to preserve the fibres from corruption, and at the same time to consolidate the whole into one compact body; or, in some sense, it may be called *lignifying* the hide, (if the term may be allowed.) This must evidently be the work of time, as the nature of the fibres must be in a great measure changed, and the new-imbibed matter incorporated and consolidated with them. In order to perform this, the hides are spread out at their full breadth and length in a vat, and a stratum of beat bark thrown between each of them. This vat holds at first as much liquor as will just cover the hides; and in this situation they are allowed to lie till the strength of the bark is thought to be exhausted, which is commonly from four to six weeks; and the operation is repeated till the hides are sufficiently tanned, and which is generally from two to four times, according to the strength of the leather. The bark should be rounder beat, and more given to the lop, for large hides than small ones; and consequently larger leather should lie longer in the lop.

Of CURRYING.

THE leather, when only tanned, is not sufficiently soft and pliable to answer a number of purposes. The currier's province is to reduce the leather to the proper thickness, pliability, and colour, requisite for the different uses to which it is applied: and though there is a material difference in the method of manufacturing the several kinds, and a good deal of dexterity required; yet what could be here said of them would be of little use to those who are unacquainted with the business. We shall therefore reduce all we are to say on this subject to a general detail of the process.

The leather, after it has dripped some time from the tannet, is shaven on an upright beam with a knife whose edge is turned on the one side, and with which the currier can take down the leather in the same manner as a wright can take a shaving from a piece of wood with his plane. After the currier has thus levelled the hide or skin to his purpose, (which is always done on the flesh-side,) he spreads it out on a stone or table made for the purpose, and there scours it on the grain-side from all the loose tan, and other stuff that may hurt the beauty of the grain. He then puts on a certain quantity of oil on both grain and flesh side, for the purpose of softening the fibres, and at the same time making them tough, and hangs it up to dry. When it is sufficiently dry, there is a thin shaving again taken off the flesh-side, in order to clean or brighten it up; and then it is rubbed backward and forward upon a table by the currier with a nicked or furrowed board, keeping the leather always doubled at the place where he rubs, till it be made soft and pliable to his intention. This last part of the operation is properly called *Currying*, and it is from this that the business gets its name. As to the colour, the leather is fair or dark in proportion to the quantity of oil laid on, if the tanning has been properly performed, and the currier do not neglect some material part of his duty. Carriers seldom dye any colour but black, which is done with coparas and a very little logwood.

TANTALUS'S

TANTALUS's CUP. See HYDROSTATICS, p. 808.

TANZY, in botany. See TANACETUM.

TAPE-WORM. See TÆNIA.

TAPESTRY, a curious kind of manufacture, serving to adorn a chamber or other apartment, by covering or lining the walls thereof. It is a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, histories, &c.

TAPPING, in general, the act of piercing an hole in a vessel, and applying a tube or canula in the aperture, for the commodious drawing off the liquors contained therein.

TAPPING, in surgery. See SURGERY, p. 655.

TAR, a thick, black, visciduous substance, obtained from old pines and fir-trees, by burning them with a close smothering heat: much used in coating and caulking ships, &c. See the article PITCH.

Water impregnated with the more soluble parts of tar, proves, in consequence of this hot pungent oil, warm and stimulating: it sensibly raises the pulse, and quickens the circulation. By these qualities, in cold, languid, phlegmatic habits, it strengthens the solids, attenuates viscid juices, opens obstructions of the minuter vessels, and promotes perspiration and the fluid secretions in general; whilst in hot bilious temperaments, it disposes to inflammation, and aggravates the complaints which it has been employed to remove.

TARACON, a city of Spain, in the province of Arragon, situated on the confines of Old Castile: W. long. 2° 6', and N. lat. 41° 55'.

TARAGON, a city and port-town of Spain, in the province of Catalonia, situated on the Mediterranean sea: in E. long. 1° 15', and N. lat. 41° 6'.

TARANTO, a port-town of Italy, in the kingdom of Naples, situated on the gulph of Otranto, forty-five miles west of that city, being the see of an archbishop.

TARANTULA, in zoology. See ARANEA.

TARE, is an allowance for the outside package, that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that inclose or bind any goods imported loose; or, though imported in casks, chests, &c. yet cannot be unpacked and weighed nett.

TARENTEAIS DUCHY, the south division of Savoy, having Piedmont on the south-east, and Savoy Proper on the north-west: subject to the king of Sardinia.

TARGET, a kind of shield or weapon of defence made use of by the ancients.

TARGUM, a name whereby the Jews call the Chaldee paraphrases, or expositions of the Old Testament in the Chaldee language. See BIBLE.

TARIF, a table or catalogue, containing the names of different sorts of merchandize, with the duties to be paid, as settled by authority, amongst trading nations.

TARPEIAN, in Roman antiquity, an appellation given to a steep rock in Rome: whence, by the law of the twelve tables, those guilty of certain crimes were precipitated.

TARSUS, in anatomy. See ANATOMY, p. 185.

TARSUS, now Terasso, once the capital of Cilicia, in the Lesser Asia, now a province of Asiatic Turkey, is situated on the north side of the Levant sea: E. long. 35°, N. lat. 37°.

TARTAR. See CHEMISTRY, p. 98, 105.

TARTARY, a vast country in the northern parts of Asia, bounded by Siberia on the north and west: this is called

Great-Tartary. The Tartars who lie south of Moscow and Siberia, are those of Afracan, Circassia, and Dagistan, situated north-west of the Caspian-sea; the Calmuc Tartars, who lie between Siberia and the Caspian-sea; the Usbec Tartars and Moguls, who lie north of Persia and India; and, lastly, those of Tibet, who lie north-west of China.

TASSEL, a sort of pendant ornament at the corners of a cushion, or the like.

In building, tassels denote those pieces of board that lie under the ends of the mantel-tees.

TASTE, in physiology, a peculiar sensation excited by means of the organs of taste, viz. the papillæ on the tongue. See ANATOMY, p. 304.

Intellectual TASTE. The external sense, with which nature has furnished us, and by which we distinguish and relish the various kinds of nourishment that are adapted to health and pleasure, has in all languages given occasion to the metaphorical word *taste*, by which we express our perception of beauty, deformity, or defect, in the several arts. *Taste* then, in general, is a quick discernment, a sudden perception, which, like the sensation of the palate, anticipates reflection; like the palate, it relishes what is good with an exquisite and voluptuous sensibility, and rejects the contrary with loathing and disgust; like the palate also, it is often doubtful, and, as it were, bewildered, not knowing whether it should relish or reject certain objects, and frequently requires the influence of habit to give it a fixed and uniform determination.

To have a taste, supposes something more than merely to perceive, and to discern with accuracy the beauty of any work or object. This beauty must be *felt*, as well as *perceived*; the mind must be touched and affected by it in a lively and sensible manner. This feeling however, in order to constitute true *taste*, must not be a vague and confused sensation; but must be attended with a distinct view, a quick and comprehensive discernment of the various qualities, in their several relations and connections, which enter into the composition of the object we contemplate. And in this we see another striking resemblance between the intellectual taste and the sensual one: for as a nice palate perceives immediately the mixture of different wines, so the man of taste will quickly discern the motley mixture of different styles in the same production; and, let the beauties and defects be ever so closely blended in an object, will always be capable of distinguishing the former from the latter.

As the corruption of the *sensual taste* discovers itself by a relish for only those delicate and high-seasoned dishes, in which all the refinements of art have been employed to excite a forced sensation of pleasure; so the depravity of the *intellectual taste* manifests itself by an attachment to far-fetched and studied ornaments, and by a want of relish for those beauties which are unaffected and natural. The corruption of the sensual taste, which makes us delight in such aliments as are disgusting to those whose organs are in a good state, is in reality a kind of disease; nor is that depravity of the intellectual taste which makes many prefer the *burlesque* to the *sublime*, and the labour'd stiffness of art to the beautiful simplicity of nature, less a disease in our mental frame.

The intellectual *taste* is much more formed by education and culture, than the sensual one; for though the

latter may be brought, by habit, to relish what at first excited loathing and disgust ; yet it does not seem to have been the intention of nature, that the generality of mankind should acquire by custom and experience those sensations and perceptions which are necessary to their preservation. It is otherwise with the *intellectual taste*: its formation requires time, instruction, and experience. A young man uninitiated in the arts of music and painting, let his natural sensibility be ever so quick and lively, will not immediately distinguish, in a grand concert of music, the various parts whose connection and relation constitute the essence and charm of the composition; nor will he perceive in a picture the gradations of light and shade, that harmony of colours, that correctness of design, which characterise a finished piece; but in process of time, and also by degrees, he learns both to hear and to see in a more perfect manner. The same uninitiated person will find a variety of emotions arise in his mind the first time he is present at the representation of a fine tragedy: but he will neither perceive the dexterity of the author in maintaining the unities; nor that exquisite art by which the drama is so managed, that no person enters upon the scene nor quits it without an evident reason; nor yet that still more nice and difficult art of making the various subordinate interests terminate and centre in one, which absorbs them all. It is only by the force of habit and reflection, that he will distinguish these several objects of *taste*, and feel delightful sensations from circumstances of which formerly he had little or no idea.

Elegant and able artists may communicate their feelings and their discernment to others, and thus excite *taste* in a nation, which, without them, had never known its refined pleasures. By frequently contemplating the works of great and eminent masters in the various arts, the powers of nature arise into taste; and we imbibe, as it were, the spirit of these illustrious men, so as to come at length to look at a gallery of paintings with the eyes of a Le Brun, a Poussin, or a Le Sueur; nay, we even read works of learning and genius with a portion of that spirit that appears in their composition.

If, in the first periods of the culture of the arts and sciences, it has sometimes happened, that a whole nation have been unanimous in the praise of authors full of defects, and whom succeeding ages have beheld with indifference, and even with contempt; the reason is, that these authors had natural beauties which were perceived by all, while that just discernment that was necessary to distinguish their numerous defects, and which is less the gift of nature, than the result of time, habit, and reflection, was as yet acquired by none. Thus Lucilius, who had been in the highest reputation among the Romans, sunk into oblivion when Horace arose; and Regnier was universally admired by the French, until Boileau appeared; and if there are several ancient authors, who have maintained their credit, notwithstanding the absurdities that are to be found in every page of their writings, it must be the authors of those nations, among whom no judicious and correct writer has appeared to open their eyes, like Horace among the Romans, and Boileau among the French.

It is a common saying, that there is no disputing about tastes: and if by the *taste* here be understood the palate, which loaths certain aliments and relishes others, the maxim is just; because it is needless to dispute about what cannot

be corrected, or to attempt reforming the constitution and mechanism of organs merely corporeal. But the maxim is false and pernicious, when applied to that *intellectual taste* which has for its objects the arts and sciences. As these objects have real charms, so there is in reality a good taste which perceives them, and a bad one which perceives them not; and there are certain methods by which we may often correct those mental defects which produce a depraved *taste*. But it must be granted, at the same time, that there are certain phlegmatic spirits, which nothing can enliven; and also certain distorted intellects, which it is impossible to rectify: with such therefore, it is in vain to dispute about tastes, because they have none at all.

In many things taste seems to be of an arbitrary nature, and without any fixed or uniform direction, such as in the choice of dress and equipage, and in every thing that does not come within the circle of the finer arts. In this low sphere it should be distinguished by the name of *fancy*; for it is *fancy*, rather than *taste*, that produces such an endless variety of new and contradictory modes.

The taste of a nation may degenerate and become extremely depraved; and it almost always happens, that the period of its perfection is the forerunner of its decline. Artists, through the apprehension of being regarded as mere imitators, strike out into new and uncommon paths, and turn aside from the beautiful simplicity of nature, which their predecessors invariably kept in view. In these efforts there is a certain degree of merit, which arises from industry and emulation, and casts a veil over the defects which accompany their productions. The public, fond of novelty, applauds their invention; but this applause is soon succeeded by satiety and disgust. A new set of artists start up, invent new methods to please a capricious taste, and depart still further from nature than those who first ventured from its paths into the wilds of fancy. Thus the taste of a people degenerates into the grossest corruption. Overwhelmed with new inventions, which succeed and efface each other with incredible rapidity, they scarcely know where they are, and cast back their eager and anxious desires towards the period when *true taste* reigned under the empire of nature. But they implore its return in vain; that happy period cannot be recalled; it deposits, however, in the custody of certain choice spirits, the sublime pleasures of *true taste*, which they cherish and enjoy in their little circle, remote from the profane eye of the depraved and capricious multitude.

There are vast countries, where *taste* has not yet been able to penetrate. Such are those uncultivated wastes, where civil society has never been brought to any degree of perfection, where there is little intercourse between the sexes, and where all representations of living creatures in painting and sculpture are severely prohibited by the laws of religion. Nothing renders the mind so narrow, and so little, if we may use that expression, as the want of social intercourse; this confines its faculties, blunts the edge of genius, damps every noble passion, and leaves in a state of languor and inactivity every principle that could contribute to the formation of *true taste*. Besides, where several of the finer arts are wanting, the rest must necessarily languish and decay, since they are inseparably connected together, and mutually support each other. This is one reason, why the Asiatics have never excelled in any of the arts; and hence also it is that *true taste* has been confined to certain countries in Europe.

TATA, or **SINDA**, the capital of a province of the same name in the Hither India, in Asia, situated at the mouth of the Indus: E. long. 68°, N. 25° 40'.

TAT-TOO, a beat of a drum at night, to advertise the soldiers to retreat or repair to their quarters in their garri-son, or to their tents in a camp.

TAU, or **Taw**, in heraldry, an ordinary in figure of a T, supposed to represent St. Andrew's cross, or a cross po-tence, the top part cut off. See **Cross**.

TAVASTUS, the capital of the province of Tavastia, in the territory of Finland in Sweden, situated eighty-four miles north-east of Abo: E. long. 24°, N. lat. 61° 20'.

TAUGHT, or **Tau't**, in the sea-language, signifies the same as stiff, or fast: thus, to set taught the shrouds or stays, is to make them more tight and stiff.

TAVISTOCK, a borough of Devonshire, thirty-two miles west of Exeter.

It sends two members to parliament, and gives the title of marquis to the noble family of Russels dukes of Bedford.

TAUNTON, a borough of Somersetshire, twenty miles south-west of Wells. It sends two members to parliament.

TAURIS, or **TABRIS**, a city of Persia, four hundred miles north of Ispahan: E. long. 46° 30', N. lat. 38° 20'.

TAURUS, the **BULL**, in zoology. See **Bos**.

TAURUS, in astronomy. See **ASTRONOMY**, p. 847.

TAUTOLOGY, a needless repetition of the same thing in different words.

TAWING, the art of dressing skins in white, so as to be fit for divers manufactures, particularly gloves, &c.

All skins may be tawed; but those chiefly used for this purpose are lamb, sheep, kid, and goat skins.

The method of tawing is this: Having cleared the skins of wool or hair, by means of lime, they are laid in a large vat of wood or stone, set on the ground full of water, in which quick-lime has been slaked; wherein they are allowed to lie a month or six weeks, according as the weather is more or less hot, or as the skins are required to be more or less soft and pliant.

While they are in the vat, the water and lime is changed twice, and the skins are taken out and put in again every day; and when they are taken out for the last time, they are laid all night to soak in a running water, to get out the greatest part of the lime; and in the morning are laid together by fives one upon another, upon the wooden leg (and are scraped stoutly one after another, to get the flesh off from the fleshy side, with a cutting two-handed in-strument called a knife; and then they cut off the legs, (if they are not cut off before.) and other superfluous parts about the extremities. Then they are laid in a vat or pit with a little water, where they are filled with wooden pestles, for the space of a quarter of an hour; and then the vat is filled up with water, and they are rinsed in it.

In the next place, they are thrown on a clean pavement to drain, and afterwards cast into a fresh pit of water, out of which they rinse them well, and are laid again on the wooden leg, six at a time, with the hair-side outmost; over which they rub a kind of whetstone very briskly, to soften and fit them to receive four or five more preparations, given them on the leg, both on the flesh-

side and the hair-side, with the knife, after the manner above mentioned.

After this they are put into a pit of water and wheaten-bran, and stirred about in it with wooden poles, till the bran is perceived to stick to them, and then they are left: as they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom; and at the same time fire is set to the liquor, which takes as easily as if it were brandy, but goes out the moment the skins are all covered.

They repeat this operation as often as the skins rise above the water; and when they have done rising they take them out, lay them on the wooden leg, the fleshy side outwards, and pass the knife over them to scrape off the bran.

Having thus cleared them of the bran, they lay the skins in a large basket, and load them with huge stones to promote their draining: and when they have drained sufficiently, they give them their feeding, which is performed after the manner following:

For one hundred of large sheep-skins, and for smaller in proportion, they take eight pounds of alum, and three of sea-salt, and melt the whole with water in a vessel over the fire, pouring the dissolution out, while yet lukewarm, into a kind of trough, in which is twenty pounds of the finest wheat flour, with the yolks of eight dozen of eggs; of all which is formed a kind of paste, a little thicker than children's pap; which, when done, is put into another vessel, to be used in the following manner.

They pour a quantity of hot water into the trough in which the paste was prepared, mixing two spoonfuls of the paste with it; to do which they use a wooden spoon, which contains just as much as is required for a dozen of skins: and when the whole is well diluted, two dozen of the skins are plunged into it; but they take care that the water be not too hot, which would spoil the paste and burn the skins.

After they have lain some time in the trough, they take them out, one after another, with the hand, and stretch them out; this they do twice; and after they have given them all their paste, they put them into tubs, and there fill them afresh with wooden pestles.

Then they put them into a vat, where they are suffered to lie for five or six days, or more; then they take them out in fair weather, and hang them out to dry on cords or racks; and the quicker they are dried the better; for if they be too long a-drying, the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are made up into bundles, and just dipt in fair water, and taken out and drained; and being thrown into an empty tub, and after having lain some time are taken out and trampled under foot.

Then they draw them over a flat iron-instrument, the top of which is round like a battledore, and the bottom fixed into a wooden block, to stretch and open them; and having been opened, they are hung in the air upon cords to dry; and being dry, they are opened a second time, by passing them again over the same instrument.

In the last place they are laid on a table, pulled out, and laid smooth, and are then fit for sale.

TAX, a tribute rated upon every town, which formerly

was wont to be paid annually into the King's-exchequer, but now not without consent of parliament; it differs from a subsidy in this, that it is always certain, as set down in the exchequer-book, and in general levied of every town, and not particularly of every man, &c. The ancient way of levying taxes was by tenths and fifteenths, afterwards by subsidies and royal aids, and at length by a pound rate; the former of these were all upon the person and personal estate, but the last upon lands and rents.

TAXUS, in botany, a genus of the diœcia monodelphia class. The calix of both male and female consists of three leaves; neither of them have any corolla; the stamina are numerous; the antheræ are rotated, and divided into eight segments; the female has no stylus; and the berry contains one seed. There are two species, only one of them, *viz.* the baccata, or yew-tree, a native of Britain.

TAY, a river of Scotland, rising from the loch or lake of Tay, in Braidalbin, and running east through Athol: it afterwards turns south-east, and dividing the counties of Perth and Angus from Strathern and Fife, falls into the frith of Tay.

TAYVEN, a city of China, in Asia, in the province of Xanfi, two hundred and forty miles south-west of Pekin: E. long. 108°, N. lat. 38° 30'.

TEA, or **THEA**, in botany, a genus of the polyandria monogynia class of plants. The corolla consists of nine petals, and the calix of five leaves; and the berry is tri-coccus. There are two species, both natives of China.

This shrub grows to five or six feet high, and is very ramose: the leaves are about an inch long, near half an inch broad, serrated, and terminating in a point. The traders in tea distinguish a vast many kinds of it, as they differ in colour, flavour, and the size of the leaf. To enumerate the several subdivisions were endless; the general division is into three kinds, the ordinary green-tea, the finer green, and the bohea; to one or other of which all the other kinds may be referred. The common green tea has somewhat small and crumpled leaves, much convoluted, and closely folded together in the drying. Its colour is a dusky-green, its taste sub-astringent, and its smell agreeable. It gives the water a strong yellowish green colour. The fine green has larger leaves, less crumpled and convoluted in the drying, and more lax in their folds; it is of a paler colour, approaching to the blue green, of an extremely pleasant smell, and has a more astringent, yet more agreeable taste than the former. It gives a pale-green colour to water. To this kind are to be referred all the higher priced green teas, the hyson, imperial, &c. The bohea consists of much smaller leaves than either of the other, and those more crumpled and closely folded than in either. It is of a darker colour than the other, often blackish; and is of the smell and taste of the others, but with a mixed sweetness and astringency. The green teas have all somewhat of the violet flavour: the bohea has naturally somewhat of the rose-smell. The leaves when gathered are dried with great caution, partly by the help of heat, partly by the air, and when thoroughly prepared will keep a long time fresh and good. Every parcel, when dried, though gathered promiscuously, is separated, according to the largeness and smallness of the leaves, into three or four different kinds, each of which is of a different price, and has its different name. The bohea tea is gathered

before the leaves are perfectly opened, and is made to undergo a greater degree of heat in the curing, to which its colour and peculiar flavour is in a great measure owing.

Tea, moderately and properly taken, acts as a gentle astringent and corroborative.

TEAL, in ornithology. See **ANAS**.

TEARS, a lymph or aqueous humour, which is subtle, limpid, and a little saltish: it is separated from the arterial blood by the lachrymal glands, and small glandulous grains on the inside of the eye-lids. See **ANATOMY**, p. 294.

TEBETH, the tenth month of the Jewish ecclesiastical year, and fourth of the civil. It answers to our month of December.

TECKLENBURG, a city of Germany, in the circle of Westphalia, capital of a county of the same name, thirteen miles south-west of Osnabrug, subject to its own count: E. long. 7° 20', N. lat. 52° 21'.

TECHNICAL, expresses somewhat relating to arts or sciences: in this sense, we say technical terms.

TE DEUM, the name of a celebrated hymn, used in the Christian church, and so called because it begins with these words, *Te Deum laudamus*; "We praise thee, O God." It is sung in the Romish church, with great pomp and solemnity, upon the gaining of a victory, or other happy event.

TEES, a river which rises on the confines of Cumberland; and running eastward divides the county of Durham from Yorkshire, and falls into the German sea below Stockton.

TEFLIS, the capital of Persian Georgia in Asia, situated on the river-Kur, or Cyrus, three hundred miles north of Tauris, and as many south of Astracan: E. long. 47° 20', N. lat. 43°.

TEGAPATAN, a port-town of the hither India, in Asia, near Cape Comorin, eighty miles south of Cochin, and a hundred and sixty north-west of Columbo in Ceylon: E. long. 76°, N. lat. 8°.

TEGUMENT, any thing that surrounds or covers another.

TEHAMA, one of the divisions of Arabia Felix in Asia, situated on the Red-sea, between the provinces of Mecca and Hadramut,

TEINTS and **SEMI-TEINTS**, in painting, denotes the several colours used in a picture, considered as more or less high, bright, deep, thin, or weakened, and diminished, &c. to give the proper relief, softness, or distance, &c. of the several objects.

TEISSE, or **TEYS**, a river of Hungary, which rises in the Carpathian mountains; and running from east to west, passes from Tokay; then turning south, passes by Zolnœck and Segedin; and having joined the river Merish, falls into the Danube, opposite to Salankamen.

TELAMON, a name given to those figures or half figures of men so commonly used, instead of columns or pilasters, to support any member in architecture, as a balcony, or the like.

TELEPHIUM, in botany, a genus of the pentandria trigynia class. The calix consists of five leaves; and the corolla of five petals, inserted into the receptacle; and the capsule has one cell and three valves. The species are two, none of them natives of Britain.

TELESCOPE. See OPTICS, p. 421.

TELESIN, a province of the kingdom of Algiers, in Africa, situated on the confines of the empire of Morocco.

TELLER, an officer of the exchequer, in ancient records called tallier. There are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith. They likewise pay all money due from the king, by warrant from the auditor of the receipt; and make weekly and yearly books, both of their receipts and payments, which they deliver to the lord treasurer.

TELLICHERRY, a port town on the Malabar coast, in the Hither India, thirty miles north of Calicut: E. lon. 75° N. lat. 12°.

TEMESWAER, the capital city of the Bannat of Temeswaer, lately annexed to Hungary, sixty miles north-east of Belgrade: E. lon. 22°, N. lat. 45° 55'.

TEMPERAMENT, among physicians, denotes the frame with constitution; or a certain habitude of the humours of the human body, whereby it may be denominated hot, cold, moist, dry, bilious, sanguine, phlegmatic, melancholic, &c.

TEMPLARS, a religious order instituted at Jerusalem, about the year 1118. Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. King Baldwin assigned them an apartment in his palace. They had likewise lands given them by the king, the patriarch, and the nobility, for their maintenance. At first there were but nine of this order, and the two principal persons were Hugo de Paganis, and Geoffrey de St Omers. About nine years after their institution, a rule was drawn up for them, and a white habit assigned them, by pope Honorius II. About twenty years afterwards, in the popedom of Eugenius III. they had red crosses sewed upon their cloaks, as a mark of distinction; and in a short time they were increased to about three hundred, in their convent at Jerusalem. They took the name of Knights Templars, because their first house stood near the temple dedicated to our Saviour at Jerusalem. This order, after having performed many great exploits against the infidels, became rich and powerful all over Europe; but the knights, abusing their wealth and credit, fell into great disorders and irregularities. Many crimes and enormities being alleged against them, they were prosecuted in France, Italy, and Spain; and at last, the pope, by his bull of the 22d of May 1312, given in the council of Vienna, pronounced the extinction of the order of Templars, and united their estates to the order of St. John of Jerusalem.

TEMPLE, a general name for places of public worship, whether pagan, Christian, or otherwise. But the word, in a restrained sense, is used to denote the places, or edifices, in which the pagans offered sacrifice to their false gods.

TEMPORAL, a term generally used for secular, as a distinction from ecclesiastical. Thus we say temporal lords, and spiritual or ecclesiastical lords.

TEMPORUM OSSA. See ANATOMY, p. 155.

TENAILLE, in fortification. See FORTIFICATION, p.

TENANT, one that holds lands or tenements of some lord, or landlord, by rent, fealty, &c. See TACK.

TENBURY, a market-town of Worcesterhire, fifteen miles north-west of Worcester.

TENBY, a port-town of Pembrokehire, situated on Bristol channel: W. lon. 4° 45', N. lat. 51° 40'.

TENCH, in ichthyology. See CYPRINUS.

TENDER, a small ship, in the service of men of war, for carrying of men, provisions, or any thing else that is necessary.

TENDONS, are white, firm, and tenacious parts, continuous to the muscles, and usually forming their extremities. See ANATOMY, Part II.

TENEBRÆ, an office in the Romish church, performed on Wednesday, Thursday, and Friday, in Passion-week, at which time neither flowers nor images are allowed to be set upon the altars, they must be covered with purple.

TENEBRIO, a genus of insects belonging to the order of coleoptera. The last joint of the antennæ is roundish; the breast is somewhat convex, and margined; and the elytra are hard. There are 33 species, principally distinguished by their colour.

TENEDOS, one of the smallest islands of the Archipelago, situated near the coast of Lesser Asia, west of the ruins of Troy, E. lon. 27°, N. lat. 39° 30'.

TENEMENT, properly signifies a house; but in a larger sense it is taken for any house, land, rent, or other thing, which a person holds of another.

TENERIF, one of the largest of the Canary Islands, situated in the Atlantic Ocean: W. lon. 17°, N. lat. 28°. being about 130 miles in circumference. It is a fruitful island, abounding in corn, wine, and oil; though pretty much incumbered with mountains, of which the most remarkable is that called the Pico of Tenerif, being one of the highest mountains in the world, in the form of a sugar-loaf, the white top whereof may be seen at sea upwards of one hundred miles.

TENES, a province of the kingdom of Algiers, in Africa. TENESMUS, in medicine, a name given, by medical writers, to a complaint which is a continual desire of going to stool, but without any stool being ready to be voided. This is usually attended with some tumour, sometimes with a very considerable one, in the part. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disease on which it is an attendant.

TENOR, or TENOUR, the purport or content of a writing or instrument in law, &c.

Act of proving the TENOR, in Scots law. See LAW, Tit. xxx. 22.

TENOR, in music, the first mean, or middle part, or that which is the ordinary pitch of the voice, when neither raised to a treble, nor lowered to a bass.

TENSE, in grammar, an inflection of verbs, whereby they are made to signify, or distinguish the circumstance of time, in what they affirm. See GRAMMAR.

TENT, in surgery, a roll of lint worked into the shape of a nail, with a broad flat head,

TENTER, a machine used in the cloth-manufacture, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square.

It is usually about four feet and a half high, and for length exceeds that of the longest piece of cloth. It consists of several pieces of wood, placed like those which

form the barriers of a *manège*; so that the lower cross piece of wood may be raised or lowered, as is found requisite, to be fixed at any height, by means of pins. Along the cross-pieces, both the upper and under one are hooked nails, called *tenter-hooks*, driven in from space to space.

TENTHREDO, a genus of insects belonging to the order of hymenoptera. The mouth is furnished with jaws, but has no proboscis; the wings are plain and tumid; the sting consists of two serrated laminae, and the scutellum of two grains placed at a distance. There are 55 species, principally distinguished by their colour, and the figure of the antennae.

TENURE, in law, signifies the manner whereby lands or tenements are held, or the service that the tenant owes to his lord. It likewise denotes the estate in the land. In England, tenures were anciently divided into the following eights; that is, land held by the service of the shield, and thereby the tenant was, at his own expence, obliged to follow his lord into the wars. Knight's service and chivalry; when lands were held of the king, or mesne lord, to perform service in war. Burgage tenure; land held of the lord of the burrow, at a certain rent. Villenage, otherwise termed *base tenure*; whereby the tenant was bound to do all inferior services, commanded by the lord. Grand serjeanty; lands held by honorary services at the king's coronation. Petit serjeanty; lands held of the king, to contribute yearly some small thing towards his wars. Frankalmoine; that tenure by which lands were held by ecclesiastics, in free and perpetual alms. Socage tenure; where lands are held by tenants, to plow their lord's lands, and perform every office of husbandry, at their own expence. But all these ancient tenures and services are in general taken away, and reduced into common and free socage. The usual tenures at present are, fee simple; which is an absolute tenure of lands to a man and his heirs for ever. Fee tail; a limited fee, to a person and the heirs of his body begotten. Curtesy tenure; where a man having married a woman seised in fee, &c. has issue born alive by her, in which case, after her death, the husband is tenant by the curtesy of England. Tenure in dower; is where a widow holds, for her life, a third part of her husband's land, whereof he was seised in fee at any time during the coverture. There is also a tenure for life, or years, when lands are held for those terms on reserved rents. Copyhold tenure, is a holding for lives, or in fee, at the will of the lord, according to the custom of the manor. For the several kinds of tenure or holding in Scotland, see *LAW*, Tit. xi.

TEPID, a term used by writers on mineral waters, &c. to express such of them as have a less sensible cold than common water.

TERCE, in Scots law. See *LAW*, Tit. xvi. 24.

TERCERA, one of the largest of the Azores or western islands, situated in the Atlantic ocean: W. long. 28°, and N. lat. 26°.

TEREBINTHUS, in botany. See *PISTACIA*.

TERES, in anatomy. See *ANATOMY*, p. 195.

TERGOWISCO, the capital of Wallachia, in European Turkey, eighty miles south-east of Hermanstadt in Transilvania: E. long. 26° 30', N. lat. 45° 35'.

TERM, in general, signifies much the same with boundary or limit.

TERM, in law, is generally taken for a limitation of time or estate: as a lease for term of life, or years.

TERM, in grammar, denotes some word or expression of a language.

TERM in the arts, or **TERM of art**, is a word which, besides the literal and popular meaning which it has, or may have, in common language, bears a further and peculiar meaning in some art or science.

TERMINALIA in antiquity, feasts celebrated by the Romans, in honour of the god Terminus.

TERMINATION, in grammar, the ending of a word, or last syllable thereof.

TERNATE, the most northerly of the Molucca or Clove-islands, in the possession of the Dutch.

TERRA. See *GEOGRAPHY*, and *ASTRONOMY*.

TERRA FIRMA, in geography, is sometimes used for a continent, in contradistinction to islands.

TERRA DEL FOGO, an island of South-America, from which it is separated by the straits of Magellan.

TERRÆ FILIUS, SON OF THE EARTH, a student of the university of Oxford, formerly appointed, in public acts, to make jesting and satirical speeches against the members thereof, to tax them with any growing corruptions, &c.

TERRACE, a walk or bank of earth, raised in a garden or court, to a due elevation, for a prospect.

TERRAQUEOUS, in geography, an appellation given to our globe, because consisting of land and water.

TERRELLA, an appellation given to a loadstone, when turned into a spherical figure, and is placed so, that its poles and equator, &c. correspond to the poles and equator of the world; as being a just representation of the great magnetical globe which we inhabit.

TERRESTRIAL, something partaking of the nature of earth, or belonging to the globe of the earth: thus we say, the terrestrial globe, &c.

TERRIER, a book, or roll, wherein the several lands, either of a private person, or of a town, college, church, &c. are described. It should contain the number of acres, and the site, boundaries, tenants names, &c. of each piece or parcel.

TERRIER is also used for a small hound. See *CANIS*.

TERRITORY, in geography, denotes an extent or compass of land, within the bounds, or belonging to the jurisdiction, of any state, city, or other subdivision of a country.

TERROUEN, a town of Artois, in the French Netherlands, situated on the river Lis, six miles south of St. Omers.

TERTIAN, in medicine. See *MEDICINE*, p. 61.

TERTIATE a great gun, in gunnery, is to examine the thickness of the metal at the muzzle, whereby to judge of the strength of the piece, and whether it be sufficiently fortified. This is usually done with a pair of caliber-compasses; and if the piece be home bored, the diameter less by the height, divided by 2, is the thickness at any place.

TERVEL, a city of Arragon, in Spain, situated on the river Guadalavira, seventy-five miles south of Saragossa: W. long. 1° 20', N. lat. 40° 35'.

TESSELATED PAVEMENTS, those of rich Mosaic work, made

made of curious square marbles, bricks, or tiles, called tessellæ, from their resembling dice.

TESSIN, a river of Italy, which, taking its rise in the Alps, runs through the country of the Grisons and the lake Maggiore; and then, turning south-east through the Milanese, passes by Pavia, and falls into the Po, a little below that city.

TEST, a vessel of the nature of the coppel, used for large quantities of metals at once.

TEST-LIQUOR, a liquor used by dealers in brandies, to prove whether they be genuine, or mixed with home-spirits. This liquor is nothing but a green or white vitriol, dissolved in fair water; for a few drops of it being let fall into a glass of old French brandy, will turn the whole to a purple, or fine violet colour; and by the strength or paleness of this colour, the dealers judge the brandy to be genuine or mixed, in different proportions, with home-spirits.

TEST-ACT, a statute 25 Car. II. cap. 2. which requires all officers, both civil and military, to take the oaths and test, *viz.* the sacrament, according to the rites and ceremonies of the church of England; for the neglect whereof, a person executing any office mentioned in that statute, forfeits the sum of 500 l. recoverable by action of debt.

TESTACEOUS, in natural history, an epithet given to animals covered with a shell, as tortoises, oysters, pearl-fish, &c.

TESTAMENT. See **LAW**, Tit. xxviii. 2.

TESTATOR, the person who makes his will and testament.

TESTES, in anatomy. See **ANATOMY**, p. 270.

TESTIMONY. See **EVIDENCE**.

TESTUDO, in zoology, a genus belonging to the order of amphibia reptilia. It has four legs and a tail, and the body is covered with a strong shell. There are 15 species, principally distinguished by peculiarities in their feet. The midas, or common turtle, is found at the Ascension isle, and many other southern islands. The shell of this animal is so strong, that several men may stand upon it without injury. It lays membranaceous eggs in round holes which it digs in the sand. The turtle is said to continue several weeks in the acts of copulation. It grows to a vast size, some having been found to weigh 480 pounds.

The Americans find so good account in catching turtle, that they have made themselves very expert at it: they watch them from their nests on shore, in moon-light nights; and, before they reach the sea, turn them on their backs, and leave them till morning; when they are sure to find them, since they are utterly unable to recover their former posture: at other times they hunt them in boats, with a peculiar kind of spear, striking them with it through the shell; and as there is a cord fastened to the spear, they are taken much in the same manner as the whales.

TESTUDO, in antiquity, was particularly used among the poets, &c. for the ancient lyre; by reason it was originally made by its inventor Mercury, of the black or hollow shell of the testudo aquatica, or sea-tortoise, which he accidentally found on the banks of the river Nile.

TESTUDO, in the military art of the ancients, was a kind of cover or screen which the soldiers, *e. gr.* a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other.

This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

TESTUDO was also a kind of large wooden tower, which moved on several wheels, and was covered with bullocks hides fixed, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

It was called testudo, from the strength of its roof, which covered the workmen as the shell does the tortoise.

TETANUS, in medicine, a convulsive motion that makes any part rigid or inflexible.

TETHYS, a genus of insects belonging to the order of vermes mollusca. The body is oblong, fleshy, and without feet; the mouth consists of a cylindrical proboscis under the duplicature of a lip; and there are two foramina at the left side of the neck. The species are two, both inhabitants of the ocean.

TETICACO, a great lake of Peru, more than two hundred miles in circumference: the towas situated on this lake are esteemed the most delightful in all South America.

TETRACERA, in botany, a genus of the polyandria tetragynia class. The calix consists of six leaves; and there are four capules. There is but one species, a native of America.

TETRACHORD, in the ancient music, a concord consisting of four degrees or intervals, and four terms or sounds; called also by the ancients diatessaron, and by us a fourth.

TETRADECARHOMBIS, in natural history, the name of a genus of fossils, of the class of the selenites, expressing a rhomboidal body, consisting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly of the same form with the common selenite; but that each of the end-planes is divided into two; and there are, by this means, eight of these planes, instead of four.

TETRADIAPASON, a musical chord, otherwise called a quadruple diapason, or eighth.

TETRADYNAMIA, in botany. See **BOTANY**, p. 635.

TETRAEDRON, in geometry, one of the five regular or platonic bodies or solids, comprehended under four equilateral and equal triangles.

TETRAGON, in geometry, a general name for any four-sided figure, as a square, parallelogram, rhombus, or trapezium.

TETRAGONIA, in botany, a genus of the icofandria pentagynia class. The calix consists of four segments; it has no corolla; and the drupa has four sides, and four cells. There are two species, both natives of Æthiopia.

TETRAGONOTHECA, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is paleaceous; it has no pappus; and the calix consists of one leaf, divided into four plain segments. There is but one species, a native of Virginia.

TETRAGRAMMATON, a denomination given by the Greeks to the Hebrew name of God, Jehovah, because consisting of four letters.

TETRANDRIA, in botany. See **BOTANY**, p. 635.

TETRAO, in ornithology, a genus of birds, of the order of gallina, distinguished by having the part of the forehead near the eyes naked and papillose. There are 20 species, distinguished principally by their colour, their having rough or naked feet, &c.

TETRA

TETRAPETALOUS, in botany, an epithet given to flowers that consist of four single petals or leaves.

TETRAPHARMACUM, signifies any remedy consisting of four ingredients.

TETRAPTERA, a name given to insects which have four wings.

TETRAPTOTE, in grammar, a name given to such defective nouns as have only four cases; such are *viciis*, *pecudis*, *ferdis*, &c. as being deprived of the nominative and vocative singular.

TETRAPYRAMIDIA, in natural history, the name of a genus of spars, influenced in their shape by an admixture of particles of tin, and found in form of broad-bottomed pyramids of four sides.

TETRARCH, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title tetrarch; but it was afterwards applied to any petty king or sovereign.

TETRASTYLE, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

TETUAN, a town of the empire of Morocco, situated about eight miles from the bay of that name, just within the straits of Gibraltar: W. long. $6^{\circ} 35'$, N. lat. $35^{\circ} 40'$.

TEUCRIUM, in botany, a genus of the didynamia gymnospermia class. The upper lip of the corolla is bipartite. There are 31 species, four of them natives of Britain, *viz.* the scordium, or water germander, the leaves of which are said to be deobstruent, diuretic, and sudorific; the chamædrys, or germander, the leaves, tops, and seeds of which are said to be sudorific, diuretic, &c.; the chamæpitys, or ground pine, the leaves of which are recommended as aperient and vulgery; and the scorodonia, or wood-sage.

TEUTONIC, something belonging to the Teutons, an ancient people of Germany, inhabiting chiefly along the coasts of the German ocean: thus, the Teutonic language is the ancient language of Germany, which is ranked among the mother tongues. The Teutonic is now called the German or Dutch.

TEUTONIC ORDER, a military order of knights, established towards the close of the twelfth century, and thus called as consisting chiefly of Germans or Teutons. The origin, &c. of the Teutonic order, is said to be this. The Christians, under Guy of Lusignan, laying siege to Acre, or Acon, a city of Syria, on the borders of the Holy Land, some Germans of Bremen and Lubec, touched with compassion for the sick and wounded of the army, who wanted common necessaries, set on foot a kind of hospital under a tent, which they made of a ship's sail, and here bestook themselves to a charitable attendance on them. This started a thought of establishing a third military order, in imitation of the templars and hospitalers. The design was approved of by the patriarch of Jerusalem, the archbishops and bishops of the neighbouring places, the king of Jerusalem, the masters of the temple and hospital, and the German lords and prelates then in the Holy Land; and pope Calixtus III. confirmed it by his bull, and the new order was called the order of the Teutonic knights of the house of St. Mary at Jerusalem. The pope granted them all the privileges of the Templars and Hospitalers of St. John, excepting that they were to be subject to the patriarchs and other prelates, and that they should pay tithe of what they possessed.

TEWKSBURY, a borough-town of Gloucestershire, situated on the river Severn, ten miles north of Gloucester.

It sends two members to parliament.

TEXEL, an island of Holland, situated at the entrance of the Zuyder-sea, parted from the continent of Holland by a narrow channel, through which most ships bound to Amsterdam pass.

TEXT, a relative term, contradistinguished to gloss or commentary, and signifying an original discourse exclusive of any note or interpretation.

TEXTURE, properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other, as in the webs of spiders, or in cloths, stufts, &c.

THALAMI nervorum opticorum. See **ANATOMY**, p. 286.

THALIA, in botany, a genus of the monandria monogynia class. The corolla consists of five waved petals; and the drupa has a double-celled nucleus. There is but one species, a native of America.

THALICTRUM, in botany, a genus of the polyandria polygynia class. The corolla consists of five petals; it has no corolla; and the seeds are naked. There are 14 species, three of them natives of Britain, *viz.* the flavum, or meadow-rue; the minus, or lesser meadow-rue; and the alpinum, or mountain meadow-rue.

THAMES, a great navigable river of England, composed chiefly of the river Isis and Thame; of which the Isis is much the largest, and runs the longest course, rising on the confines of Gloucestershire. At Lechlade it becomes navigable, from whence it continues its course north-east to Oxford, where it receives the Charwell; from Oxford it runs south-east to Abington, and so to Dorchester, where it receives the Thame, and continues its course south-east to Windsor, and thence runs east to London, and continues the same course to the sea, receiving the river Medway near the mouth of it. The Thame is but a small river, which rising near Tring in Hertfordshire, crosses the county of Bucks, and falls into the Isis at Dorchester.

THANE, or **THAIN**, a name of an ancient dignity among the English and Scots, or Anglo-Saxons. Skene makes thane to be a dignity equal to the son of an earl. Camden will have it, that thanes were only dignified by the offices they bore. There were two kinds or orders of thanes; the king's thanes, and the ordinary thanes. The first were those who attended the king in his courts, and who held lands immediately of the king. The ordinary thanes, or the *thani minores*, were the lords of the manors, who had particular jurisdiction within their limits, and over their own tenants; these changed their names for that of barons, and hence their courts are called courts-baron to this day.

THANET, a little island of east Kent, formed by the English and Scots, or Anglo-Saxons. Skene makes thane to be a dignity equal to the son of an earl. Camden will have it, that thanes were only dignified by the offices they bore. There were two kinds or orders of thanes; the king's thanes, and the ordinary thanes. The first were those who attended the king in his courts, and who held lands immediately of the king. The ordinary thanes, or the *thani minores*, were the lords of the manors, who had particular jurisdiction within their limits, and over their own tenants; these changed their names for that of barons, and hence their courts are called courts-baron to this day.

THAPSIA, in botany, a genus of the pentandria digynia class. The fruit is oblong, and surrounded with a membrane. There are four species, none of them natives of Britain.

THAWING, the resolution of ice into its former fluid state, by the warmth of the air, &c. See **FREEZING**.

THEA in botany. See **TEA**.

THEATINES, a religious order in the Romish church, so called

- called from their principal founder John Peter Caraffa, then bishop of Theate, or Chiere, in the kingdom of Naples, and afterwards pope, under the name of Paul IV. The names of the other founders were Gaetan, Boniface, and Configlieri. These four pious men, desiring to reform the ecclesiastical state, laid the foundation of an order of regular clerks at Rome, in the year 1524. Pope Clement VII. approved the institute, and permitted the brethren to make the three religious vows, to elect a superior every three years, and to draw up statutes for the regulation of the order. They first endeavoured, by their example, to revive among the clergy the poverty of the apostles and first disciples of our Saviour, and were the first who assumed the title of regular clerks.
- THEATRE**, a public edifice for the exhibiting of scenic spectacles, or shows, to the people; comprehending not only the eminence on which the actors appear, and the action passes, but also the whole area of the place common to the actors and spectators.
- THEBAID**, a celebrated heroic poem of Statius, the subject whereof is the civil war of Thebes, between the two brothers Eteocles and Polynices; or, Thebes taken by Thebes.
- THEBES**, the name of an ancient city in upper Egypt, now in ruins; as also an ancient city of Achaia, now a province of European Turkey.
- THEFT**. See **LAW**, Tit. xxxiii. 28.
- THEISM**. See **DEISM**.
- THELEGONUM**, in botany, a genus of the monœcia polyandria class. The calix both of male and female consists of two segments; neither of them have any corolla; the stamina are 12; and the female has one stylus, and a coriaceous capsule, with one cell and one seed. There is but one species, a native of Italy.
- THEME**, denotes the subject of an exercise, for young students to write or compose on.
- THENAR**, in anatomy. See **ANATOMY**, p. 200.
- THEOBROMA**, the **CHOCOLATE-NUT-TREE**, in botany, a genus of the polyadelphia pentandria class. The corolla consists of five petals; the nectarium is bell-shaped; and the fruit is a woody cortex, of an unequal surface, with five ridges. There are two species, both natives of America.
- THEOCRACY**, in matters of government, a state governed by the immediate direction of God alone: such was the ancient government of the Jews, before the time of Saul.
- THEODOLITE**, a mathematical instrument much used in surveying. See **GEOMETRY**, p. 701.
- THEOGONY**, that branch of the heathen theology, which taught the genealogy of their gods.
- THEOLOGY**. See **RELIGION**.
- THEOPHRASTA**, in botany, a genus of the pentandria monogynia class. The corolla is bell-shaped, with obtuse segments; and the capsule has one round large cell, and one seed. There is but one species, a native of America.
- THEOREM**, a speculative proposition, demonstrating the properties of any subject.
- THEORETIC**, something relating to theory, or that terminates in speculation. See **THEORY**.
- THEORY**, in general, denotes any doctrine which terminates in speculation.
- nates in speculation alone, without considering the practical uses and application thereof.
- THERAPEUTE**, a term applied to those who are wholly employed in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.
- THERAPEUTICS**, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed in the cure of diseases.
- THERAPHIM**, certain images, or superstitious figures, mentioned in Scripture. Some Jewish writers tell us, the theraphim were effigies of human heads, placed in niches, and consulted as oracles. Others say, they were talismans, or figures of metal, cast and engraved under certain aspects of the planets; to which they ascribed extraordinary effects.
- THERIACA ANDROMACHI**, a compound medicine, made in the form of an electuary.
- THERMÆ**, artificial hot baths, much used by the Romans.
- THERMOMETER**, an instrument for measuring the increase and decrease of the heat and cold of the air, by means of the elastic and expansive power of bodies of the fluid sort. See **PNEUMATICS**, p. 486.
- THESEA**, in antiquity, feasts celebrated by the Athenians, in honour of Theseus, consisting of sports and games, with mirth and banquets: such as were poor, and unable to contribute to them, were entertained at the public expence.
- THESIS**, a general position which a person advances, and offers to maintain. In colleges it is frequent to have placards, containing a number of them, in theology, in medicine, in philosophy, in law, &c.
- THESIAM**, in botany, a genus of the pentandria monogynia class. The calix consists of one leaf, into which the stamina are inserted; there is but one seed. The species are seven, only one of them, viz. the linophyllon, or ballard toad-flax, a native of Britain.
- THESSALY**, now called Janna, a province of European Turkey, bounded by Macedonia, on the north; by the Archipelago, on the east; by Achaia, or Livadia, on the south; and by Epirus, on the west.
- THETFORD**, the county-town of Norfolk, situated twenty-five miles south-west of Norwich. It sends two members to parliament.
- THEURGY**, a name given to that part of magic called white magic, or the white art. Those who have written of magic have divided it into three kinds: the first is theurgy, as operating by divine means: the second, natural magic, performed by the powers of nature: and the third, necromancy, which they imagined proceeded from invoking demons.
- THIBET**, one of the most powerful of the Tartar kingdoms, having China on the east, and India on the west.
- THIGH**, in anatomy. See **ANATOMY**, p. 182, 203.
- THIMBLE**, an instrument made of brass, silver, iron, &c. put on the finger to thrust a needle through any cloth, silk, &c. used by all seamstresses, tailors, &c.
- THINKING**, a general name for any act or operation of the mind. See **LOGICK**, and **METAPHYSICS**.
- THIRLAGE**. See **LAW**, Tit. xvi. 12.
- THIRSK**, a borough-town in the north-riding of Yorkshire.

shire, situated on the river Swale, sixteen miles north-west of York. It sends two members to parliament.

THIRST, an uneasy sensation, arising from a deficiency in the saliva to moisten the inward parts of the mouth; hence arises a strong desire for drink: it is a symptom generally attending feverish disorders.

THISTLE, in botany. See **CARDUUS**.

Order of the THISTLE, or of St Andrew, a military order of knighthood in Scotland, the rise and institution whereof is variously related by different authors. Lesley, bishop of Ross, reports, that the night before the battle between Athelstan king of Northumberland, and Hungus king of the Picts, a bright cross, in form of that whereon St Andrew (the tutelar saint of Scotland) suffered martyrdom, appeared to Hungus; who having gained the victory, ever after bore the figure of that cross on his banners. Others assert, that Achaius king of Scotland first instituted this order, after having made the famous league offensive and defensive with Charlemagne king of France. But although the thistle had been acknowledged as the symbol of the kingdom of Scotland from the reign of Achaius, yet some refer the beginning of this order to Charles VII. of France. Others place the foundation of it as low as the year 1500.

The chief and principal ensign is a gold collar composed of thistles and sprigs of rue interlinked with amulets of gold, having pendent thereunto the image of St Andrew with his cross, and the motto, *NEMO ME IMPUNE LACESSIT*.

The ordinary or common ensign worn by the knights, is a star of four silver points, and over them a green circle, bordered and lettered with gold, containing the said motto, and in the centre is a thistle proper; all which is embroidered on their left breast, and worn with the collar, with a green ribband over the left shoulder, and brought under the right arm; pendent thereto is the image of St Andrew, with his cross, in a purple robe, within an oval of gold enamelled vert, with the former motto: but sometimes they wear, encircled in the same manner, a thistle crowned.

About the time of the reformation, this order was dropped, till James II. of England resumed it, by creating eight knights: however, the revolution unfetted it again, and it lay neglected till queen Anne, in 1703, restored it to the primitive design, of twelve knights of St Andrew.

THLASPI, in botany, a genus of the tetradynamia siliculosa class. The pod is emarginated, heart-shaped, containing many seeds. There are ten species, six of them natives of Britain, viz. the campestre, or mithridate; the arvense, or treacle-mustard; the perfoliatum, or perfoliate treacle-mustard; the furtum, or perennal mithridate mustard; the montanum, or mountain mithridate-mustard; and the bursa pastoris, or shepherd's purse.

THOMÆANS, **THOMISTS**, or *Christians of St Thomas*, a people of the East-Indies, who, according to the tradition, received the Gospel from St Thomas. Upon the arrival of the Portuguese at Calicut, in their first voyage to the Indies, they met with ancient Christians, who pretended to be descended from those converted by St Thomas. The Thomæans being informed of a new people arrived among them, who bore a particular veneration for the

cross, sent ambassadors to them, to make an alliance with them, and to solicit their assistance against the Gentile princes, by whom they were greatly oppressed. A mixture of opinions, with a total interruption of pastors, sometimes for several years together, occasioned that horrible chaos their religion was in at the arrival of the Portuguese; for a specimen whereof we shall add their manner of celebrating the eucharist: Over their altar was a kind of gallery; and while the priest was saying the beginning of the office below, a cake of flour of rice was frying in oil, or butter, above; when enough, the cake was let down in a basket upon the altar, where the priest consecrated it: as to the other species, for wine they used a kind of brandy or arrack, variously prepared in that country. Nor was their ordination much more regular; the archdeacon, who was sometimes more respected than the bishop himself, frequently ordained priests: their other abuses were infinite. The Portuguese, for these two last centuries, have laboured the reformation of this church, and have employed both the ecclesiastic and secular power therein: for this end they have called the Thomæan bishops to the council at Goa, have instructed, charged them, &c. and even sent them for instruction to Portugal and Rome; but finding that they were still apt to relapse at their return, and that no good was like to be done with them, they resolved to exclude them once for all, and to appoint an European bishop in their room. These proceedings have rendered the Portuguese infinitely odious to the Thomæans.

St THOMAS, a city of the hither India, on the coast of Coromandel, three miles south of Fort St George; subject to the Portuguese.

St THOMAS is also an island in the Atlantic ocean, situated under the equator, in 8° E. long.

St THOMAS is also a town of Guiana, in South America, situated on the river Oronoko; subject to Spain.

St THOMAS'S DAY, a festival of the Christian church, observed on Dec. 21. in commemoration of St Thomas the apostle.

St THOMAS of Canterbury's day, a festival of the Romish church, observed on Dec. 29. in memory of Thomas Becket archbishop of Canterbury, who was murdered, or, as the Romanists say, martyred, in the reign of king Henry II.

THOMISM, the doctrine of St Thomas Aquinas. and his followers the Thomists, chiefly with regard to predestination and grace. There is some doubt what the true genuine thomism is, but there are authors who distinguish the thomism of St Thomas from that of the dominicans. Others again make thomism no other than a kind of jansenism disguised: but jansenism, it is known, has been condemned by the popes, which pure thomism never was: in effect, the writings of Alvarez and Lemos, who were appointed by their order to lay down and defend, before the holy see, the dogmata of their school, have since been reputed the rule of pure thomism.

THOMISTS, a sect of school-divines, who maintain thomism. See the preceding article.

THORACIC DUCT. See **ANATOMY**, p. 282.

THORAX, in anatomy. See **ANATOMY**, p. 277.

THORN, a city of Poland, in the province of regal Prussia, situated on the river Vistula: E. long. 19°, and N. lat. 52° 40'.

THORN.

THORNBAC, in ichthyology. See **RATA**.

THORNBURY, a market-town of Gloucestershire, situated twenty miles south-west of Gloucester.

THORNEY-ISLAND, an island made by the branches of the Thames formerly, where Westminster-abbey now stands.

THORNEY-ISLAND is also an island situated in a bay of the East channel, between Chichester and Portsmouth.

THOUGHT, a general name for all the ideas consequent on the operations of the mind, and even for the operations themselves.

THOULON, or **TOULON**, a port-town of Provence, in France, situated on a bay of the Mediterranean sea : E. E. long. 6°, and N. lat. 43° 5'.

THOULOSE, or **TOULOSE**, a city of France, capital of the city of Languedoc, situated on the river Garonne : E. long. 1° 5', and N. lat. 43° 40'.

THRACE, a province of European Turkey, situated on the north side of the Propontis.

THRASHING, or **THRESHING**, in agriculture, the art of beating the corn out of the ears.

There are two ways of separating corn from the ear ; the first by beating it with a flail, which is properly what is called thrashing. The other method, still practised in several countries, is to make mules, or horses, trample on it, backwards and forwards ; this is properly what the ancients called tritura and trituration. The Hebrews used oxen therein, and sometimes yoked four together for this purpose. Another way among the ancients was with a kind of sledge, made of boards joined together, and loaded with stones or iron, upon which a man was mounted, and the whole drawn over the corn by horses : this instrument was called traba, or tribula.

THRAVE of corn, twenty-four sheaves, or four shocks of six sheaves to the shock ; though, in some countries, they only reckon twelve shocks to the thrave.

THRICHCHIUS, in zoology, a genus of quadrupeds belonging to the order of bruta. There are no fore-teeth in either jaw ; the dog-teeth in the upper jaw are solitary ; the lips are doubled ; and in place of the two hind legs, they have a broad fleshy tail or fin. There are two species, viz. 1. The rosmarinus, morse, sea-horse, or wall-rose, has the dog-teeth of the upper-jaw protruded out of the mouth. This animal is found in the ocean, within the polar circle. It grunts like a hog, and is about the size of a bull. 2. The monatus, or sea-cow, has the dog teeth not protruded. It is found in the American and Indian ocean, principally at the mouths of rivers. It feeds upon sea-weeds, and is about twelve feet long. The females have, between the pectoral fins, two large, round, and fair breasts ; and both sexes have the parts of generation, and the navel, perfectly resembling those of the human species : there is no doubt but all the fables concerning mermaids, mermen, and syrens, took their rise from an imperfect view of this animal.

THRIPS, a genus of insects belonging to the order of hemiptera. The beak is obscure ; the feelers are of an equal length with the breast ; the body is linear ; and it has four strait wings lying cross-ways upon the back.

There are five species, distinguished by their colour.

THROAT, the anterior part of an animal, between the head and the shoulders, wherein is the gullet.

THRONE, a royal seat, or chair of state, enriched with

ornaments of architecture and sculpture, raised on one or more steps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings and other sovereigns.

THROWSTER, one who prepares raw silk for the weaver, by cleansing and twisting it.

THRUSH, in ornithology. See **TURDUS**.

THULE, of the ancients, supposed to be the islands of Orcaades.

THUMB, in anatomy, one of the parts or extremities of the hand. See **ANATOMY**, p. 181.

THUMMIM. See **URIM**.

THUNDER, a noise in the regions of the air, excited by sudden flashes of lightning. See **ELECTRICITY**, p. 480, 484.

THURINGIA LANDGRAVIATE, one of the divisions of the circle of Upper Saxony, in Germany, having the duchy of Magdeburg on the north, and Franconia on the south.

THURSDAY, the fifth day of the Christian week, but the sixth day of that of the Jews.

THURSO, a port-town of Caithness, in Scotland, situated on the Caledonian ocean, fifteen miles south-west of Dunby-head.

THUYA, in botany, a genus of the monœcia monadelphica class. The calix of the male is an amentum, that of the female a strobilus ; neither of them have any corolla ; there is one pistillum, and one nut surrounded with an emarginated wing. The species are three, all natives of warm countries.

THYMUS, in botany, a genus of the didynamia gymnospermia class. The calix is bilabiate, and the stamens are shut up with hairs. There are eight species, two of them natives of Britain, viz. the ferpillum, or common thyme ; and the acinos, or wild basil.

THYMUS, in anatomy. See **ANATOMY**, p. 278.

THYROARYTÆNOIDES, in anatomy. See **ANATOMY**, p. 301.

THYROIDE CARTILAGE. See **ANATOMY**, p. 300.

THYRSUS, in antiquity, the sceptre which the poets put into the hand of Bacchus. And wherewith they furnished the menades in their bacchanalia.

TIARA, an ornament or habit wherewith the ancient Persians covered their head ; and which the Armenians, and kings of Pontus, still wear on medals ; these last, however, descended from the Persians.

TIARA is also the name of the pope's triple crown.

TIBER, a great river of Italy, which runs through the pope's territories, passing by Perugia and Orvietto ; and having visited Rome, falls into the Tuscan sea at Ostia, fifteen miles below that city.

TIBIA, in anatomy. See **ANATOMY**, p. 183.

TIBIALIS, in anatomy. See **ANATOMY**, p. 209.

TIDES. See **ASTRONOMY**, p. 473.

TIDE-WAITERS, or **TIDEMEN**, are inferior officers belonging to the custom-house, whose employment it is to watch or attend upon ships, until the customs be paid ; they get this name from their going on board ships, on their arrival in the mouth of the Thames or other port, and so come up with the tide.

TIEND, in Scots law. See **LAW**, Tit. xvii. 1, &c.

TIERCE, or **TEIRCE**, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons.

TIERCED

TIERCED, in heraldry, denotes the shield to be divided by any part of the partition-lines, as party, coupé, trançhy, or taily, into three equal parts of different colours or metals.

TIGER, in zoology. See **FELIS**.

TIGRIS, a large river of Turkey in Asia, which, rising in the mountains of Armenia, runs southward, dividing Diarbeck or Mesopotamia, from Curdistan or the ancient Assyria; and having passed by Badgat, joins the Euphrates in Eyraca Arabic, or the ancient Chaldaea.

TILBURY, a fortress in the county of Essex, situated on the river Thames, opposite to Graveland, twenty miles east of London.

TILIA, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals, and the calix of five segments; the berry is dry, and round, with five cells, and five valves. There are two species, only one of them, *viz.* the *Europæa*, or lime-tree, a native of Britain.

TILLEA, in botany, a genus of the tetrandria tetragynia class. The calix consists of three segments, and the corolla of three equal petals; and there are three capsules containing three seeds. The species are two, none of them natives of Britain.

TILLANDSIA, in botany, a genus of the hexandria monogynia class. The calix consists of three persistent segments; the corolla is bell-shaped, with three segments; the capsule has one cell, containing a single pappous seed. There are nine species, none of them natives of Britain.

TILLER of a ship, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the helm.

TILLAGE. See **AGRICULTURE**, p. 54.

TIMAR, a tract or portion of land, which the grand seignior grants to a person on condition of serving him in a war on horse-back. Hence, those who enjoy such lands are called timariots.

TIMBER, includes all kinds of felled and seasoned woods.

TIME, a succession of phenomena in the universe; or a mode of duration marked by certain periods or measures, chiefly by the motion and revolution of the sun. See **ASTRONOMY**, p. 489.

TIME, in music, is an affection of sound, whereby we determine it long or short, with regard to its continuance in the same degree of time. See **MUSIC**.

TIMOR, an island in the Indian ocean, situated between 122° and 126° of east long, and between 8° and 10° south lat.

It is in possession of the Dutch, and said to have gold mines.

TIN. See **CHEMISTRY**, p. 83, 105, 135.

TINCTURE, in pharmacy and chemistry, a separation of the finer and more volatile parts of a mixed body, made by means of a proper menstruum dissolving and retaining the same.

TINCTURE, in heraldry, the hue or colour of any thing in coat armour, under which denomination may be also included the two metals, or and argent, because they are often represented by yellow and white.

TINE. There are two rivers of this name; the one called North-Tine, which rises on the borders of Scotland; and the other South-Tine, which rises on the confines of Cumberland; the one running south-east, and the other

north-east: they unite their waters at Hexham, and continuing to run east, divide the counties of Durham and Northumberland, passing by Newcastle, and falling into the German sea at Tinnmouth.

TINMOUTH, a port-town of Northumberland, situated on the German sea, at the mouth of the river Tine, seven miles east of Newcastle.

TINNING, the covering or lining any thing with melted tin, or with tin reduced to a very fine leaf. Looking-glasses are foliated, or tinned, with thin plates of beaten tin, the whole bigness of the glass, applied or fastened thereto by means of quicksilver. See **FOLIATING**.

TINNITUS AURIS. See **MEDICINE**, p. 156.

TINUS, in botany, a genus of the enneandria monogynia class. The calix consists of five segments, and the corolla of five petals; the berry has three cells, containing one seed. There is but one species, a native of Jamaica.

TIPPERARY, a county of Ireland, in the province of Munster, lying between King's-county on the north, and Waterford on the south.

TIPSTAFF, an officer who attends the judges with a kind of staff tipped with silver, and takes into his charge all prisoners who are committed or turned over at a judge's chambers.

TIRE, in the sea-language, is a row of cannon placed along a ship's side, either above upon deck, or below, distinguished by the epithets of upper and lower tires.

TIROI, a country of Germany, in the circle of Austria, about one hundred and twenty miles long, and sixty broad, subject to the house of Austria: it is bounded by Swabia and Bavaria on the north.

TITANS, in the heathen mythology, the offspring of Titan, the elder brother of Saturn; upon whom, and his son Jupiter, they made war, in order to recover the sovereignty of which Titan had been deprived. The poets represent them as a race of giants, sprung from the earth, and invading heaven; and tell us, that Jupiter overcame them with thunder, and drove them down to the very bottom of hell.

TITNES. See **TITEND**.

TITLE, an appellation of dignity or quality, given to princes, and other persons of distinction.

TITMOUSE, in ornithology. See **PARUS**.

TITUBATION, a kind of libration, or shaking, which the ancient astronomers attributed to the crystalline heavens, in order to account for certain irregularities which they observed in the motions of the planets.

TITULAR, denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he perform the functions thereof or not.

TINTERTON, a borough of Devonshire, situated on the river Ex, thirteen miles north of Exeter. It sends two members to parliament.

TIVIOT, or **CHEVIOT-MOUNTAINS**, are high hills on the borders of England and Scotland.

TMESIS, in grammar, a figure whereby a compound word is separated into two parts, and one or more words placed between them: thus, for *quæcunque*, Virgil says, *quæ me cunque vocant terra*, &c.

TOAD, in zoology. See **RANA**.

TOAD-FLAX, in botany. See **ANTIRRHINUM**.

TOBACCO, in botany. See **NICOTIANA**.

TOBAGO, a small island in the bay of Panama, in South-

- South-America**, situated W. long 82° , N. lat. 8° .
- TOBAGO**, is also the name of one of the Caribbee islands.
- TOBOLSKI**, the capital of Siberia, situated at the confluence of the rivers Tobal and Iris: E. long. 63° , N. lat. $57^{\circ} 30'$.
- TOCAT**, the capital of Amasia, in Asia: E. long. 37° , and N. lat. $41^{\circ} 30'$.
- TOCKAY**, a city of Hungary, seventy miles north-east of Buda, the wines of which are esteemed the best in Europe.
- TOES**. See **ANATOMY**, p. 188.
- TOGA**, in Roman antiquity, a wide woollen gown, or mantle; which seems to have been of a semi-circular form, without sleeves; differing both in richness and largeness, according to the circumstances of the wearer, and used only upon occasion of appearing in public.
- Every body knows that the toga was the distinguishing mark of a Roman: hence, the *jus togæ*, or privilege of the toga, was the same with the privilege of a Roman citizen, *i. e.* the right of wearing a Roman habit, and of taking, as they explain it, fire and water through the Roman empire.
- TOILS**, snares or nets used by hunters for catching wild beasts, as deer, &c.
- TOILET**, a fine cloth of linnen, silk, or tapestry, spread over the table in a bed-chamber or dressing-room, to undress and dress upon.
- TOISE**, a French measure containing six of their feet, or a fathom.
- TOLEDO**, a city of New Castile, in Spain; the archbishop of which is primate of Spain, &c. and possesses the largest revenue of any archbishop of Europe: it is situated in W. long. $4^{\circ} 12'$, and N. lat. $39^{\circ} 45'$.
- TOLEN**, the capital of an island of the same name, in the province of Zealand, in the united Netherlands, situated four miles north-west of Bergenopzoom.
- TOLERATION**, in matters of religion, is either civil or ecclesiastical. Civil toleration, is an immunity and safety granted by the state to every sect that does not maintain doctrines inconsistent with the public peace; and ecclesiastical toleration, is the allowance which the church grants to its members to differ in certain opinions not reputed fundamentals.
- TOLLENON**, among the Romans, a warlike machine, formed in this manner: One beam was fixed very deep in the earth, and on the top of it another more than twice as long, and moveable upon a centre; on one end of this cross-beam were placed a covering of hurdles or planks, within which a few soldiers were put, and by pulling down the other end with ropes, these were raised above the walls of a besieged town.
- TOLU**, a port-town of Terra Firma, situated on a bay of the North-Sea, an hundred miles south-west of Cartagena.
- TOLUIFERA**, in botany, a genus of the decandria monogynia class. The calix is bell-shaped, and has five segments; the corolla has five petals, the lowest being longest, and somewhat cordated; it has no styles. There is but one species, a native of America.
- TOMB**, includes both the grave or sepulchre wherein a deceased is interred, and the monument erected to preserve his memory.

- TOME**, in matters of literature, denotes a bound book, or writing that just makes a volume.
- TOMENTUM**, among botanists, the downy matter which grows on the leaves of some plants.
- TOPE**, or **TUNE**, in music, a property of sound, whereby it comes under the relation of grave and acute; or it is the degree of elevation a sound has, from the degree of swiftness of the vibrations of the part of sonorous bodies. See **MUSICK**.
- TONGUE**, in anatomy. See **ANATOMY**, p. 304.
- TONQUIN**, a kingdom of the further India, bounded by the provinces of Yunam and Canton, in China, on the north; by Cochinchina, on the south; and by the kingdom of Laos, on the west; lying between 101° and 108° E. long. and between 17° and 26° N. lat. Its capital is Keccio, or Cachao.
- TONSILS**, in anatomy. See **ANATOMY**, p. 303.
- TONSURE**, in ecclesiastical history, a particular manner of shaving or clipping the hair of ecclesiastics or monks.
- The ancient tonsure of the clergy was nothing more than polling the head, and cutting the hair to a moderate degree, for the sake of decency and gravity: and the same observation is true, with respect to the tonsure of the ancient monks. But the Romanists have carried the affair of tonsure much farther; the candidate for it kneeling before the bishop, who cuts the hair in five different parts of the head, *viz.* before, behind, on each side, and on the crown.
- TOOL**, among mechanics, denotes in general any small instrument, used as well for making other more complex instruments and machines, as in most operations in the mechanic arts.
- TOOTH**, in anatomy. See **ANATOMY**, p. 164.
- TOOTH-ACH**. See **MEDICINE**, p. 120.
- TOPARCHY**, a little state or feignory, consisting only of a few cities or towns: or a petty country, governed and possessed by a toparch or lord.
- TOPAZ**, in natural history, a gem called by the ancients chrysolite, as being of a gold-colour.
- The topaz, when perfect and free from blemishes, is a very beautiful and valuable gem; it is, however, very rare in this state. It is of the number of those gems which are found only in the round or pebble form, there never having been yet seen a true and genuine topaz of a columnar figure, though the far greater part of what our jewellers call such, are in that form. The greatest part of the true topazes are no larger than grains of a coarse seed; among these there are, however, some met of the size of a pea, and some much larger, though these are very rare. It is of a roundish or oblong figure in its native or rough state, and is usually flattened on one side, and is generally of a bright and naturally polished surface, tolerably transparent. They are ever of a fine yellow colour; but they have this, like the other gems, in several different degrees: the finest of all are of a true and perfect gold colour; but there are some much deeper, and others extremely pale, so as to appear scarce tinged. The oriental topaz is equal to the ruby in hardness, and is second only to the diamond in lustre.
- TOPHUS**, in medicine, denotes a chalky or stony concretion in any part of the body, as the bladder, kidney, &c. but especially in the joints.

TOPICAL MEDICINES, are the same with external ones, or those applied outwardly to some diseased and painful part: such are plasters, cataplasms, unguents, &c.

TOPOGRAPHY, a description or draught of some particular place, or small track of land; as that of a city or town, manor or tenement, field, garden, house, cattle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TORBAY, a fine bay in the English channel, a little east of Dartmouth.

TORCELLA, a port town of Catalonia, in Spain, situated at the mouth of the river Ter, in E. long. $2^{\circ} 50'$, and N. lat. 42° .

TORCH, a luminary used in several church-ceremonies, funerals, &c. and more usually called flambeau.

TORCH-THISTLE, in botany. See **CACTUS**.

TORDYLIUM, in botany, a genus of the pentandria digynia class. The radii of the corolla are all hermaphrodites; the fruit is roundish, with a crenated edge; and the involucre is long, and undivided. There are seven species, only two of them natives of Britain, viz. the latifolium, or purple-flowered great bastard parsley; and the nodosum, or knotted parsley.

TORUS, in architecture, a large round moulding, used in the bases of columns.

TORIES, in the history of England, a faction or party, opposed to the whigs. See **WHIGS**.

The Tories are great sticklers for the prerogative of the crown, as the whigs are for the liberties and privileges of the people; though, in truth, the principles of the moderate people of both parties do not greatly differ.

TORMENTILLA, in botany, a genus of the icosaandra polygynia class. The calix consists of eight segments, and the corolla of four petals; the seeds are roundish, naked, and fixed to a small dry receptacle. There are two species, both natives of Britain, viz. the erecta, or tormentil, and the reptans, or creeping tormentil.

Tormentil-root has an austere styptic taste, accompanied with an aromatic flavour: it is one of the most agreeable and efficacious vegetable astringents.

TORNADO, a sudden and vehement gust of wind from all points of the compass, frequent on the coast of Guinea.

TORNE, the capital of Torne Lapmark, a province of Sweden, situated at the mouth of the river Torne, at the bottom of the Bothnic gulph, upon a little island made by the river, four hundred miles north of Stockholm: E. long. $22^{\circ} 45'$, N. lat. $65^{\circ} 45'$.

TORPEDO, in ichthyology. See **RAJA**.

TORQUE, in heraldry, denotes a round roll of cloth, twisted and stuffed: such is the bandage, frequently seen in armories, about the heads of moors, &c.

TORREFACTION, in chemistry, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation; as sulphur is thus discharged from an ore, before the metal can be obtained to advantage.

TORRENT, denotes a temporary stream of water, falling suddenly from mountains, whereon there have been great rains, or an extraordinary thaw of snow.

TORRICELLIAN EXPERIMENT, a famous experiment made by Torricelli, a disciple of the great Galileo, which

has been already explained in the Treatise of PNEUMATICS, p. 485.

TORRINGTON, a market-town of Devonshire, situated on the river Towbridge, twenty six-miles north-west of Exeter.

TORTOISE, in zoology. See **TESTUDO**.

TORTURE, a grievous pain inflicted on a criminal, or person accused, to make him confess the truth.

TOTNESS, a borough-town of Devonshire, twenty-three miles south-west of Exeter. It sends two members to parliament.

TOUCAN, in ichthyology. See **RAMPHASTOS**.

TOUCAN, in astronomy, p. 487.

TOUCH-NEEDLE, among assayers, refiners, &c. little bars of gold, silver, and copper, combined together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touch stone with those of the bars.

The metals usually tried by the touch-stone, are gold, silver, and copper, either pure, or mixed with one another in different degrees and proportions, by fusion. In order to find out the purity or quantity of baser metal in these various admixtures, when they are to be examined they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminæ or plates, one twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The black rough marbles, the basaltæ, or the softer kinds of black pebbles, are the most proper for touch-stones.

Now the method of using the needles and stone is this: the piece of metal to be tried, ought first to be wiped well with a clean towel, or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person will, in some degree, judge beforehand what the principal metal is, and how and with what debased.

Then chuse a convenient, not over large, part of the surface of the metal, and rub it several times very hardly and strongly against the touch-stone, that in case a deceitful coat or crust should have been laid upon it, it may be worn off by that friction: this, however, is more readily done by a grind-stone, or small file. Then wipe a flat and very clean part of the touch-stone, and rub against it, over and over, the just mentioned part of the surface of the piece of metal, till you have, on the flat surface of the stone, a thin metallic crust, an inch long, and about an eighth of an inch broad: this done, look out the needle that seems most like to the metal under trial, wipe the lower part of this needle very clean, and then rub it against the touch-stone, as you did the metal, by the side of the other line, and in a direction parallel to it.

When this is done, if you find no difference between the colours of the two marks, made by your needle and the metal under trial, you may with great probability pronounce that metal and your needle to be of the same alloy, which is immediately known by the mark engraved

on your needle. But if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried, choose out another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touch-stone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what alloy it is of, by the mark of the needle; or else you will find that the alloy is extraordinary, and not to be determined by the comparison of your needles.

TOURINE, a town of the bishopric of Liege, thirteen miles north-east of Namur.

TOURNEY, a city of Flanders, in the Austrian Netherlands, situated on the river Scheld, thirteen miles east of Lille: E. long. $3^{\circ} 30'$, and N. lat. $50^{\circ} 37'$.

TOURNEFORTIA, in botany, a genus of the pentandria monogynia class. The berry has two cells containing two seeds, perforated with two holes at the apex. There are eight species, none of them natives of Britain.

TOURNEQUET, in surgery, an instrument made of rollers, compresses, screws, &c. for compressing any wounded part, so as to stop hæmorrhages. See **SURGERY**.

TOWER, a tall building, consisting of several stories, usually of a round form, though sometimes square or polygonal.

Towers are built for fortresses, prisons, &c. as the Tower of London, the Tower of the Balliol, &c.

TOWN, a place inhabited by a considerable number of people, being of a middle size between a city and village.

TOXICODENDRON, in botany. See **RHUS**.

TOZZIA, in botany, a genus of the didynamia angiospermia class. The calix has five teeth; and the capsule is round, with one cell, containing a single seed. There is but one species, a native of Switzerland.

TRACHEA, in anatomy. See **ANATOMY**, p. 300.

TRACHELIUM, in botany, a genus of the pentandria monogynia class. The corolla is funnel-shaped; the stigma is globular; and the capsule has three cells. There is but one species, a native of Italy.

TRACHINUS, in ichthyology, a genus belonging to the order Jugularis. The head is small, smooth, and compressed; there are six rays in the membrane of the gills; the plates of the opercula are serrated; and the anus is near the breast. There is but one species, viz. the draco, a native of the northern ocean.

TRACT, in geography, an extent of ground, or a portion of the earth's surface.

TRACT, in matters of literature, denotes a small treatise, or written discourse upon any subject.

TRADE. See **COMMERCE**.

TRADE-WINDS. See **PNEUMATICS**, p. 495.

TRADESCANTIA, in botany, a genus of the hexandria monogynia class. The calix consists of three leaves, and the corolla of three petals; the filaments are villous; and the capsule has three cells. There are three species, all natives of warm countries.

TRADITION, among ecclesiastical writers, denotes certain regulations regarding the rites, ceremonies, &c. of religion, which we suppose to have been handed down from the days of the apostles to the present time.

TRADITION, in Scots law. See **LAW**, Tit viii. 10.

TRAFFIC. See **COMMERCE**.

TRAGACANTH, in botany. See **ASTRAGALUS**.

Gum-tragacanth is the produce of this shrub, which grows to about four feet high, and has a firm and robust stem, with numerous branches. The gum is brought to us in long and slender pieces, of a flattened figure, more or less; and these not straight, or rarely so; but commonly twisted and contorted various ways, so as to resemble worms.

Tragacanth has the same virtues with gum-arabic, but in a greater degree. It greatly inspissates and obtunds the acrimony of the humours, and is therefore found of vast service in inveterate coughs, and other disorders of the breast.

TRAGEDY, a dramatic poem, representing some signal action performed by illustrious persons, and which has frequently a fatal issue, or end. See **COMPOSITION**.

TRAGICOMEDY, a dramatic piece partaking of the nature both of tragedy and comedy; the event whereof is not bloody or unhappy, and wherein is admitted a mixture of less serious characters.

TRAGIA, in botany, a genus of the monœcia tetrandria class. The calix of the male consists of three segments, that of the female of five; neither of them have any corolla; the stylus is trifid; and the capsule has three cells, with solitary seeds. There are five species, none of them natives of Britain.

TRAGOPOGON, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is naked; the calix is simple, and consists of many leaves; and the pappus is feathered. There are eleven species, two of them natives of Britain, viz. the pratense, or yellow goat's-beard; and the porifolium, or purple goat's-beard.

TRAGUS, in anatomy. See **ANATOMY**, p. 295.

TRAJAN COLUMN, a famous historical column erected in Rome, in honour of the emperor Trajan. It is of the Tuscan order, though something irregular; its height is eight diameters, and its pedestal Corinthian: it was built in a large square there, called Forum Romanum. Its base consists of twelve stones, of an enormous size, and it is raised on a socle, or foot of eight steps; within side is a stair-case, illuminated with forty four windows. It is 140 feet high, which is thirty-five short of the Antonine column, but the workmanship of the former is much more valued. It is adorned from top to bottom with basso relievo's, representing the great actions of that emperor against the Dacæ.

TRAJECTORY of a comet, is its path or orbit, or the line it describes in its motion. See **ASTRONOMY**, p. 444.

TRAIN, a line of gun-powder, laid to give fire to a quantity thereof, in order to do execution by blowing up earth, works, buildings, &c.

TRAIN OF ARTILLERY, includes the great guns, and other pieces of ordnance belonging to an army in the field.

TRAIN-OIL, the oil procured from the blubber of a whale by boiling.

TRAINING, or **TRACING**, in mineralogy, a term used by the miners, to express the tracing up the mineral appearances on the surface of the earth to their head, or original place, and there finding a mine of the metal they contain. See **MINE**.

TRALOS MONTES, a province of Portugal, bounded by Spain on the north-east; by the province of Beira on the south; and by Entreminho Douro on the west.

TRANSACTION, an accommodation of some business.

- or dispute between two parties, by a mutual and voluntary agreement between them.
- TRANSCENDENTAL**, or **TRANSCENDANT**, something elevated, or raised above other things; which passes and transcends the nature of other inferior things.
- TRANSCRIPT**, a copy of any original writing, particularly that of an act, or instrument, inserted in the body of another.
- TRANSFER**, in commerce, &c. an act whereby a person surrenders his right, interest, or property in any thing moveable or immoveable to another.
- TRANSFORMATION**, in general, denotes a change of form, or the assuming a new form different from a former one. The chemists have been for a long time seeking the transformation of metals; that is, their transmutation, or the manner of changing them into gold.
- TRANSFERENCE**, in Scots law. See **LAW**, Tit. xxx. 25.
- TRANSFUSION**, the act of pouring a liquor out of one vessel into another.
- TRANSGRESSION**, an offence against some law, or a breach or violation thereof.
- TRANSILVANIA**, a principality bounded by the Carpathian mountains, which divide it from Poland on the north; by Moldavia on the east; by Walachia, and part of Hungary, on the south; and by another part of Hungary on the north; being about 120 miles long, and almost as many broad; and lying between 22 and 25 degrees east long, and between 45 and 48 of north lat.
- TRANSIT**, in astronomy, signifies the passage of any planet, just by, or over a fixed star, or the sun, and of the moon in particular, covering or moving over any planet. See **ASTRONOMY**, p. 438.
- TRANSITIVE**, in grammar, an epithet applied to such verbs as signify an action which passes from the subject that does it, to or upon another subject which receives it. Under the head of verbs transitive, come what we usually call verbs active and passive; other verbs, whose action does not pass out of themselves, are called neuters.
- TRANSLATION**, the act of transferring or removing a thing from one place to another; we say the translation of a bishop's see, a council, a seat of justice, &c.
- TRANSLATION** is also used for the version of a book or writing out of one language into another.
- TRANSMARINE**, something that comes from, or belongs to, the parts beyond sea.
- TRANSMIGRATION**, the removal or translation of a whole people into another country, by the power of a conqueror.
- TRANSMIGRATION**, is particularly used for the passage of a soul out of one body into another, being the same with what we otherwise call metempsychosis. See **METEMPSYCHOSIS**.
- TRANSMUTATION**, the act of transforming or changing one nature into another.
- TRANSMUTATION**, in alchemy, denotes the art of changing or exalting imperfect metals into gold or silver. This is also called the grand operation, and, they say, is to be effected with the philosopher's stone.
- TRANSOM**, among builders, denotes the piece that is framed across a double light window.
- TRANSOM**, in a ship, a piece of timber which lies athwart the stern, between the two fashion-pieces, directly under the gun-room port. See **SHIP-BUILDING**.
- TRANSPARENCY**, in physics, a quality in certain bodies, whereby they give passage to the rays of light; in contradistinction to opacity, or that quality of bodies which renders them impervious to the rays of light.
- TRANSPiration**, the insensible, or almost insensible, passage of an excrementitious matter through the pores of the skin, called also perspiration.
- TRANSPLANTATION**, in agriculture and gardening, the act of removing trees or plants from the places where they were sowed, or raised, and planting them in others.
- TRANSPORTATION**, the act of conveying or carrying a thing from one place to another.
- TRANSPPOSITION**, in grammar, a disturbing or dislocating of the words in a discourse, or a changing of their natural order of construction, to please the ear by rendering the texture more easy, smooth, and harmonious.
- TRANSPPOSITION**, in music. See **MUSIC**.
- TRANSUBSTANTIATION**, in theology, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ, which the Romish church hold is wrought by the consecration of the priest.
- ADION OF TRANSUMPT**, in Scots law. See **LAW**, Tit. xxx. 27.
- TRANSVERSALIS**, in anatomy. See **ANATOMY**, p. 193.
- TRANSVERSE**, something that goes across another, from corner to corner: thus bends and bars, in heraldry, are transverse pieces or bearings: the diagonals of a parallelogram or a square, are transverse lines.
- TRAPA**, in botany, a genus of the tetrandria monogynia class. The corolla consists of four petals; and the calyx of four segments; and the nut has four spines opposite to one another. There is but one species, a native of Asia.
- TRAPEZIUM**, in geometry, a plane figure contained under four unequal right lines.
- TRAPEZIUS**, in anatomy. See **ANATOMY**, p. 193.
- TRAVERSE**, or **TRANSVERSE**, in general, denotes something that goes athwart another; that is, crosses and cuts it obliquely.
- TRAVERSE**, in navigation, is a compound course, wherein several different successive courses and distances are known. See **NAVIGATION**.
- TRAVESTY**, a French term, derived from the verb *travestir*, to disguise one's self, or to appear in masquerade: and hence, travesty is applied to the disguising of an author, or the translating him into a style and manner different from his own, by which means it becomes difficult to know him.
- TREACLE**. See **THERIACA**.
- Some also give the name treacle to melleasses.
- TREASON**, in general, signifies betraying; but is more particularly used for the act or crime of infidelity to one's lawful sovereign. See **LAW**, Tit. xxxiii. 9.
- TREASURE**, in general, denotes a store or stock of money in reserve.
- TREASURER**, an officer to whom the treasure of a prince or corporation is committed, to be kept, and duly disposed of.
- The lord high treasurer of Great Britain, or first commissioner of the treasury, when in commission, has under his charge and government all the king's revenue, which is kept in the exchequer. He holds his place during the king's pleasure, being instituted by the delivery of a white

staff to him : he has the check of all the officers employed in collecting the customs and other royal revenues ; and in his gift and disposition are all the officers of the customs in the several ports of the kingdom ; escheators in every county are nominated by him ; he also makes leases of the lands belonging to the crown.

TREASURY, the place wherein the revenues of a prince are received, preserved, and disbursed.

Lords of the TREASURY. In lieu of one single director and administrator of his majesty's revenues under the title of lord high treasurer, it is at present thought proper to put that office in commission, *i. e.* to appoint several persons to discharge it with equal authority, under the title of lords commissioners of the treasury.

TREATISE, a set discourse in writing on any subject. A treatise is supposed more express, formal, and methodical than an essay, but less so than a system.

TREATY, a covenant between two or more nations ; or the several articles or conditions stipulated and agreed upon between sovereign powers.

TREBLE, in music, the highest or acutest of the four parts in symphony, or that which is heard the clearest and shrillest in a concert.

TREE, the first and largest of the vegetable kind, consisting of a single trunk, out of which spring forth branches and leaves.

TREFOIL. See **TRIFOLIUM**.

Marjib-TREFOIL, in botany. See **MENYANTHES**.

Shrub TREFOIL, in botany. See **CYTISUS**.

TREMELLA, **LAVER**, in botany, a genus of sea-plants, of a middle nature, between the alga and conferva, being of a pellucid and membranaceous, and frequently of a gelatinous structure. There are nine species, six of them natives of Britain.

TREMOR, an involuntary shaking, chiefly of the hands and head, sometimes of the feet, and sometimes of the tongue and heart.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach more securely to the place attacked ; whence they are also called lines of approach.

TRENT BISHOPRICK, a province of Germany, in the circle of Austria, situated on the Alps, which divides Italy from Germany, and sometimes reckoned part of Italy ; it is bounded by Tyrol on the north, by the territory of Venice on the east and south, and by the country of the Grisons on the west, being seventy miles long and fifty broad, subject to the house of Austria.

TRENT is also the name of one of the largest rivers in Great Britain, rising in the moor-lands of Staffordshire, and running south-east by Newcastle Under Line, divides that country almost into two equal parts ; then entering Derbyshire, turns about to the north-east ; and having run the whole length of Nottinghamshire, continues its course due north ; at last joining the river Ouse, and several others, it changes its name to that of Humber, and falls into the German sea below Hull.

TREPAN. See **SURGERY**, p. 664.

TREPANNING, in surgery. See **SURGERY**, *ibid*.

TRESPASS, in law, signifies any transgression of the law, under treason, felony, or misprision of either ; but it is most commonly used for any wrong or damage that is done

by one private person to another, or to the king in his forest, &c.

TRESSURE, in heraldry, a diminutive of an orle, usually held to be half the breadth thereof. See it represented in Plate CXLVII. fig. 20.

TRET, in commerce, an allowance made for the waste, or the dirt, that may be mixed with any commodity, which is always four pounds in every one hundred and four pounds weight.

TRIAL, in law, the examination of a cause, civil or criminal, according to the laws of the land, before a proper judge : or, it is the manner and order observed in the hearing and determining of causes.

TRIANDRIA, in botany. See **BOTANY** p. 635.

TRIANGLE, in geometry, a figure of three sides and three angles. See **GEOMETRY**, p. 686.

TRIANGULARIS, in anatomy. See **ANATOMY**, p. 306.

TRIBE, in antiquity, a certain quantity or number of persons, when a division is made of a city or people into quarters or districts.

TRIBRACHYS, in ancient poetry, a foot consisting of three syllables, and those all short ; as *melius*.

TRIBULUS, in botany, a genus of the decandria monogynia class. The calix consists of five segments, and the corolla of five open petals ; it has no stylus ; and there are five gibbous, bristly capsules, containing many seeds. There are four species, none of them natives of Britain.

TRIBUNAL, in general, denotes the seat of a judge, called in our courts *bench*.

TRIBUNES, among the ancient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunes of the people were first established in the year of Rome 259. The first design of the creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine mount, whither they had retired in displeasure.

Their number, at first, was but two ; but the next year, under the consulate of A. Posthumus Aruncius and Cassius Viscellinus, there were three more added ; and this number of five was afterwards increased by L. Trebonius to ten. The appellation *tribune* was given them, by reason they were at first chosen out of the tribunes of the army.

Military TRIBUNE, an officer in the Roman army, who commanded in chief over a body of forces, particularly the division of a legion, much the same with our colonel, or the French *mestre de camp*.

TRIBUTARY, one who pays tribute to another, in order to live in peace with him, or share in his protection, **TRIBUTE**, a tax or impost which one prince or state is obliged to pay to another as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

TRICEPS, in anatomy. See **ANATOMY**, p. 205.

TRICHOSTEMA, in botany, a genus of the didynamia gymnospermia class. The upper lip of the corolla is falcated ; and the stamina are very long. There are two species, both natives of America.

TRICUSPIDES VALVE, in anatomy. See **ANATOMY**, p. 279.

TRIDENT, an attribute of Neptune, being a kind of sceptre which the painters and poets put into the hands of that god, in form of a spear, or fork, with three teeth; whence the word.

TRIEMIMERIS, a kind of caesura in Latin verse, wherein after the first foot of the verse there remains an odd syllable, which helps to make up the next foot.

TRIENNIAL, an epithet applied chiefly to offices or employments which last for three years.

TRIENS, in antiquity, a copper money of the value of one third of an as which on one side bore a Janus's head, and on the other a water-rat.

TRIENTALIS, in botany, a genus of the heptandria monogynia class. The calix consists of seven leaves, and the corolla of seven equal plane segments; and the berry is dryish. There are two species, none of them natives of Britain.

TRIERS, or **TREVES**, the capital of the electorate of Triers in Germany, situated on the river Moselle, sixty miles south of Cologne: E. long. $6^{\circ} 10'$, N. lat. $49^{\circ} 55'$.

TRIESTE, a port-town of Istria, situated on the gulph of Venice, sixty miles north-east of that city.

TRIFOLIUM, in botany, a genus of the diadelphia decandria class. The flowers are subcapitated; the pod is hardly longer than the calix, and deciduous. There are 43 species, 16 of them natives of Britain.

TRIGA, in antiquity, denotes a kind of carr, or chariot, drawn by three horses; whence the name.

TRIGLA, in ichthyology, a genus of fishes, belonging to the order of thoraciceæ. The head is loricated with rough lines, and there are seven rays in the membrane of the gills; There are nine species.

TRIGLOCHIN, in botany, a genus of the hexandria trigynia class. The calix consists of three leaves, and the corolla of three petals; and it has no stylus. There are two species, both natives of Britain, viz. the palustre, or arrow-headed grass; and the maritimum, or sea spiked grass.

TRIGLYPHS, in architecture, a sort of ornaments repeated at equal intervals in the Doric frieze.

TRIGONELLA, in botany, a genus of the diadelphia decandria class. The vexillum and alæ are nearly equal, open, and in the form of a corolla, with three petals. There are 10 species, none of them natives of Britain.

T R I G O N O M E T R Y.

TRIGONOMETRY is that part of geometry which teaches how to measure the sides and angles of triangles.

Trigonometry is either plane or spherical, according as the triangles are PLANE or SPHERICAL; of each whereof we shall treat in order.

PLANE TRIGONOMETRY.

PLANE Trigonometry, or that which teaches the mensuration of plane triangles, is commonly divided into *rectangular* and *oblique-angular*.

Of RECTANGULAR PLANE TRIGONOMETRY.

IF in any right angled triangle, ABC, (Plate CLIX. fig. 1. n^o 1.) the hypothenuse be made the radius, and with that a circle be described on the one end, A, as a centre; then, it is plain, that BC will be the sine of the angle BAC; and if with the same distance, and on the end B as a centre, a circle be described, it is plain, that AC will be the sine of the angle ABC: therefore, in general, if the hypothenuse of a right-angled triangle be made the radius, the two legs will be the sines of their opposite angles.

Again, if in a right-angled triangle DEF (*ibid*. n^o 2.) one of the legs, as DF, be made the radius, and on the extremity D (at one of the oblique angles, viz. that which is formed by the hypothenuse and the leg made radius) as a centre, a circle be described; it is plain, that the other leg, EF, will be the tangent of the angle at D, and the hypothenuse DE will be the secant of the same angle. The same way, making the leg EF the radius, and on the center E describing a circle, the other leg DF will become the tangent of the angle at E, and the hypothenuse DE the secant of the same.

The chord, sine, tangent, &c. of any arch, or angle, in

one circle, is proportionable to the chord, sine, tangent, &c. of the same arch in any other circle: from which, and what has been said above, the solutions of the several cases of rectangular trigonometry naturally follow.

Since trigonometry consists in determining angles and sides from others given, there arise various cases; which being seven in rectangular-trigonometry, are as follows.

CASE I. The angles, and one of the legs, of a right-angled triangle being given, to find the other leg.

EXAMPLE. In the triangle ABC (*ibid* n^o 3.) right-angled at B, suppose the leg AB=86 equal parts, as feet, yards, miles, &c. and the angle A=33° 40'; required the other leg BC, in the same parts with AB.

I. *Geometrically*: Draw AB=86 from any line of equal parts; upon the point B, erect the perpendicular BC; and, lastly, from the point A, draw the line AC, making with AB an angle of 33° 40'; and that line produced will meet BC in C, and so constitute the triangle. The length of BC may be found by taking it in your compasses, and applying it to the same line of equal parts that AB was taken from.

II. *By calculation*: First, by making the hypothenuse AC radius, the other two legs will be the sines of their opposite angles, viz. AB the sine of C, and CB the sine of A. Now since the sine, tangent, &c. of any arch in one circle is proportionable to the sine, tangent, &c. of the same arch in any other circle, it is plain the sines of the angles A and C in the circle described by the radius AC, must be proportional to the sine of the same arches or angles, in the circle, that the table of artificial sines, &c. was calculated for; so the proportion for finding BC will be

$$S. C. AB : S. A : BC$$

i. e. as the sine of the angle C in the tables, is to the length of AB (or sine of C in the circle whose radius is AC) so is the sine of the angle A in the tables, to the length of BC

BC (or sine of the same angle in the circle whose radius is A C.) Now the angle A being $33^{\circ} 40'$, the angle C must be $56^{\circ} 20'$; therefore looking in the table of artificial sines, &c, for the sines of the two angles, and in the table of logarithms for the logarithm of 86 the given leg, we shall find, by proceeding according to the foregoing proportion, that the required leg BC is 57.28; and the operation will stand as follows:

| | | |
|---------|------|------------------|
| 1.93450 | AB | 86 |
| 9.74380 | S, A | $33^{\circ} 40'$ |
| <hr/> | | |
| 1.67830 | | |
| 9.92027 | S, C | $56^{\circ} 20'$ |

1.75803 BC 57.28

Secondly, making AB the radius, it is plain BC, the leg required, will be the tangent of the given angle A; and so the proportion for finding BC, when AB is made the radius, will be:

$$R : T, A :: AB : BC$$

i. e. as the radius in the tables, is to the tangent of the angle A in the same; so the length of BA, or radius in the scheme, to the length of BC or tangent of A in the scheme: therefore looking in the tables for the parts given in the foregoing proportion, and proceeding with them according to that rule, we shall find BC to be 57.28 as before, and the operation will be as follows:

| | | |
|---------|------|------------------|
| 9.82352 | T, A | $33^{\circ} 40'$ |
| 1.93450 | AB | 86 |

11.75802
10.00000 Rad. 90°

175802 BC 57.28

Lastly, by making BC, the leg required, the radius, it is plain that AB will be the tangent of C, and the proportion for finding BC will be as follows:

$$T, C : R :: AB : BC$$

| | | |
|---------------------------|------------------|----------|
| i. e. as the tangent of C | $56^{\circ} 20'$ | 10.17648 |
| is to radius | 90° | 10.00000 |
| so is the length of AB | 86 | 1.93450 |

11.93450
10.17648

to the length of BC 57.28 1.75802
CASE II. The angles and one of the legs given, to find the hypotenuse.

EXAMPLE: In the triangle ABC, (*ibid.* n^o 4.) suppose AB 124, and the angle A $34^{\circ} 20'$; consequently the angle C $55^{\circ} 40'$, required the hypotenuse AC, in the same parts with A B.

I. Geometrically: This case is constructed after the same manner with the former; and the hypotenuse, AC, is found, by taking its length in your compasses, and applying that to the same line of equal parts from which AB was taken.

II. By calculation: First, making AC the radius, we shall have the following proportion for finding A C, viz.

$$S, C : R :: AB : AC$$

| | | |
|------------------------|------------------|----------|
| i. e. as the sine of C | $55^{\circ} 40'$ | 9.91686 |
| is to radius | 90° | 10.00000 |
| so is AB | 124 | 2.09342 |
| to AC | 150.2 | 2.17656 |

Secondly, making AB the radius, we have this proportion, viz.

$$R : \sec. A :: AB : AC.$$

| | | |
|---------------------|------------------|----------|
| i. e. as the radius | 90° | 10.00000 |
| to the secant of A | $34^{\circ} 20'$ | 10.08314 |
| so is AB | 124 | 2.09342 |
| to AC | 150.2 | 2.17656 |

This may also be done, without the help of the secants: for since $R : \sec. :: Co-S : R$; therefore, the former proportion will become,

$$Co-S, A : R :: AB : AC.$$

| | | |
|---------------------------|------------------|----------|
| i. e. as the co-sine of A | $34^{\circ} 20'$ | 9.91686 |
| is to the radius | 90° | 10.00000 |
| so is AB | 124 | 2.09342 |
| to AC | 150.2 | 2.17656 |

Thirdly, making BC the radius, we have the following proportion, viz.

$$T, C : \sec. C :: AB : AC.$$

| | | |
|---------------------------|------------------|----------|
| i. e. as the tangent of C | $55^{\circ} 40'$ | 10.16558 |
| is to sec. C | $55^{\circ} 40'$ | 10.2872 |
| so is AB | 124 | 2.09342 |
| to AC | 150.2 | 2.17656 |

This likewise may be done without the help of secants; for since $T : \sec. :: S : R$; therefore the former analogy will be reduced to this, viz.

$$S, C : R :: AB : AC,$$

where no secants do appear; and it coincides with that in the first supposition of this case, so we shall not repeat the operation.

CASE III. The angles and hypotenuse given, to find either of the legs.

EXAMPLE. In the triangle ABC, (*ibid.* n^o 4.) suppose the hypotenuse AC = 146, and the angle A = $36^{\circ} 25'$; consequently the angle C = $53^{\circ} 35'$; required the leg AB.

I. Geometrically: Draw the line AB at pleasure, and make the angle BAC equal to $36^{\circ} 25'$; then take AC equal to 146 from any line of equal parts; lastly, from the point C, let fall the perpendicular CB, on the line AB. So the triangle is constructed, and AB may be measured from the line of equal parts

II. By calculation: First, making AC the radius, we shall have the following proportion, viz.

$$R : S, C :: AC : AB.$$

| | | |
|------------------|------------------|----------|
| i. e. As radius | 90° | 10.00000 |
| to the sine of C | $53^{\circ} 35'$ | 9.90565 |
| so is AC | 146 | 2.16435 |
| to AB | 117.5 | 2.07000 |

Secondly, making AB the radius, we have the following analogy, viz.

$$\sec. A : R :: AC : AB.$$

| | | |
|--------------------------|------------------|----------|
| i. e. As the secant of A | $36^{\circ} 25'$ | 10.09435 |
| is to radius | 90° | 10.00000 |
| so is AC | 146 | 2.16435 |
| to AB | 117.5 | 2.07000 |

This may also be done without the help of secants; for since $\sec. : R :: R : Co-S$, the former proportion may be reduced to this, viz.

$$R : Co-S, A :: AC : AB,$$

which is the same with the proportion in the first supposition. Thirdly, by supposing BC the radius, we have the following proportion, viz.

$$\sec. C : T, C :: AC : AB,$$

| | | |
|--------------------------|------------------|----------|
| i. e. as the secant of C | $53^{\circ} 35'$ | 10.22647 |
|--------------------------|------------------|----------|

is to the tangent of C $53^{\circ} 35'$ 10.13212
 so is AC 146 2.16435
 to AB 117.5 2.07000

CASE IV. The two legs being given, to find the angles.

EXAMPLE. In the triangle ABC, (*ibid.* n^o 5.) suppose AB 94, and BC 56, required the angles A and C.

I. *Geometrically*: Draw AB equal to 94, from any line of equal parts; then from the point B raise BC perpendicular to AB, and take BC from the former line of equal parts equal to 56; lastly, join the points A and C with the straight line AC: so the triangle is constructed, and the angles may be measured by a line of chords.

II. *By calculation*: First, supposing AB the radius, we have this analogy, *viz.*

$$AB:BC::R:T, A,$$

i. e. as AB 94 1.97313
 is to BC 56 1.74819
 so is the radius 90^o 10.00000
 to the tangent of A 30^o 47' 9.77506

Secondly, making BC the radius, we have this proportion, *viz.*

$$BC:BA::R:T, C.$$

i. e. as BC 56 1.74819
 is to AB 94 1.97313
 so is the radius 90^o 10.00000
 to the tangent of C 59^o 13' 10.22494

CASE V. The hypotenuse and one of the legs given, to find the angles.

EXAMPLE. In the triangle DEF, (*ibid.* n^o 6.) suppose the leg DE=83, and the hypotenuse DF=126; required the angles D and F.

I. *Geometrically*: Draw the line DE=83 from any line of equal parts; and from the point E raise the perpendicular EF: then take the length of DF=126, from the same line of equal parts; and setting one foot of your compasses in D, with the other crosses the perpendicular EF in E: lastly, join D and F; and the triangle being thus constructed, the angles may be measured by a line of chords.

II. *By calculation*: First, making DF the radius, we shall have this proportion, *viz.*

$$DF:DE::R:S, F.$$

i. e. as DF 126 2.10037
 is to DE 83 1.91908
 so is radius 90^o 10.00000
 to the sine of F 41^o 12' 9.81871

Secondly, by supposing DE the radius, we have the following analogy, *viz.*

$$DE:DF::R:\text{Sec. D.}$$

i. e. as DE 83 1.91908
 is to DF 126 2.10037
 so is radius 90^o 10.00000
 to the secant of D 48^o 48' 10.18129

This may be done without the help of secants; for since R: sec.: Co-S.: R, the foregoing analogy will become this, *viz.*

$$DF:DE::R:\text{Co-S. D.}$$

which gives the same answer with that deduced from the first supposition.

CASE VI. The two legs being given, to find the hypotenuse.

EXAMPLE: In the triangle ABD, (*ibid.* n^o 7.) suppose the leg AB=64, and BD=56: required the hypotenuse.

I. *Geometrically*: The construction of this case is performed the same way as in the fourth case, and the length of the hypotenuse is found by taking it in your compasses, and applying it to the same line of equal parts that the two legs were taken from.

II. *By calculation*: This case being a compound of the fourth and second cases, we must first find the angles by the fourth, thus:

$$AB:DB::R:T, A.$$

i. e. as the leg AB 64 1.80618
 is to the leg DB 56 1.74819
 so is the radius 90 10.00000
 to the tangent of A 41^o 11' 9.94201

Then by the second case we find the hypotenuse required thus:

$$S, A:R::BD:AD,$$

i. e. as the sine of A 41^o 11' 9.81854
 is to the radius 90^o 10.00000
 so is the leg BD 56 1.74819
 to the hypoth. AD 85.05 1.92965

This case may also be solved after the following manner, *viz.*

From twice the logarithm of the greater

side AB

subtract the logarithm of the lesser

side BD

and there remains

the logarithm of 73.15; to which adding the lesser side BD, we shall have 189.15, whose logarithm is 2.11093 to which add the logarithm of the lesser

side BD

and the sum will be

the half of which is

the logarithm of the hypotenuse required.

Or it may be done by adding the square of the two sides together, and taking the logarithm of that sum, the half of which is the logarithm of the hypotenuse required; thus, in the present case,

the square of AB (64) is 4096

the square of BD (56) is 3136

the sum of these squares is 7232

the logarithm of which is 3.85926

the half of which is 1.92962

to the logarithm of 85.05, the length of the hypotenuse required.

CASE VII. The hypotenuse and one of the legs being given, to find the other leg.

EXAMPLE. In the triangle BGD, (*ibid.* n^o 8.) suppose the leg BG=87, and the hypotenuse BD=142; required the leg DG.

I. *Geometrically*: The construction here is the same as in case V. the same things being given; and the leg DG is found by taking its length in your compasses, and applying that to the same line of equal parts the others were taken from

II. *By calculation*: The solution of this case depends upon the 11th and 5th; and first we must find the oblique angles by case 5th thus:

$$DB:BG::R:S, D.$$

i. e. as the hypoth. DB 142 2.15229
 is

is to the leg BG 87 1.93952
 fo is radius 90°, 10.00000
 to the fine of D 37°, 47' 97.8723
 Then by case 1st, we find the leg DG required, thus:
 R : S, B :: B D : D G,

i. e. as radius 90° 10.00000
 is to the fine of B 52°, 13' 9.89781
 fo is the hypoth. DB 142 2.15229
 to the leg DG 112.2 2.05010

The leg DG may also be found in the following manner, *viz.*

To the log of the sum of the hypotenuse and }
 given leg, *viz.* 229 } 2.35984
 add the logarithm of their difference, *viz.* 55 1.74036

and their sum is 4.10020
 the half of that is 2.05010
 the log. of 112.2 the leg required.

Or it may be done by taking the square of the given leg from the square of the hypotenuse, and the square root of the remainder is the leg required : thus, in the present case,

The square of the hypotenuse (142) is 20164
 The square of the leg BG (87) is 7569

Their difference is 12595
 Whose logarithm is 4.10020
 The half of which is 2.05010

which answers to the natural number 112.2 the leg required.

Thus have we gone through the seven cases of right-angled plane trigonometry ; from which we may observe, 1. That to find a side, when the angles are given, any side may be made the radius. 2. To find an angle, one of the given sides must of necessity be made the radius.

OF OBLIQUE-ANGLED PLANE TRIGONOMETRY.

IN oblique-angled plane trigonometry there are six cases ; but before we shew their solution, it will be proper to premise the following theorems.

THEOREM I. In any triangle ABC (*ibid.* fig. 2. n° 2.) the sides are proportional to the sines of its opposite angles : thus, in the triangle ABC, A B : B C :: S. C : S. A, and A B : A C :: S. C : S. B : also A C : B C :: S. B : S. A.

Demonstration. Let the triangle ABC be inscribed in a circle ; then, it is plain (from the property of the circle) that the half of each side is the sine of its opposite angle : but the sines of these angles, in tabular parts, are proportional to the sines of the same in any other measure ; therefore, in the triangle ABC, the sines of the angles will be as the halves of their opposite sides ; and since the halves are as the wholes, it follows, that the sines of the angles are as their opposite sides ; *i. e.* S, C : S, A :: A B : B C, &c.

THEOR. II. In any plane triangle, as ABC (*ibid.* n° 2.) the sum of the sides, AB and BC, is to the difference of these sides, as the tangent of half the sum of the angles BAC, ABC, at the base, is to the tangent of half the difference of these angles.

Demon. Produce AB ; and make BH equal to BC ; join HC, and from B let fall the perpendicular BE ; through B draw BD parallel to AC, and make HF equal to CD,

and join BF ; also take BI equal to BA, and draw IG parallel to BD or AC.

Then it is plain that AH will be the sum, and HI the difference of the sides AB and BC ; and since HB is equal to BC, and BE perpendicular to HC, therefore HE is equal to EC ; and BD being parallel to AC and IG, and AB equal to BI, therefore CD or HF is equal to GD, and consequently HG is equal to FD, and half HG is equal to half FD or ED. Again, since HB is equal to BC, and BE perpendicular to HC, therefore the angle EBC is half the angle HBC ; but the angle HBC is equal to the sum of the angles A and C, consequently the angle EBC is equal to half the sum of the angles A and C. Also, since HB is equal to BC, and HF equal to CD, and the included angles BHF BCD equal, it follows that the angle HBF is equal to the angle DBC, which is equal to BCA ; and since HBD is equal to the angle A, and HBF equal to BCA, therefore FBD is the difference, and EBD half the difference of the two angles A and BCA : so making EB the radius, it is plain EC is the tangent of half the sum, and ED the tangent of half the difference of the two angles at the base. Now IG being parallel to AC, the triangles HIG and HAC will be equiangular ; consequently AH : IH :: CH : GH ; but the wholes are as their halves, therefore AH : IH :: $\frac{1}{2}$ CH : $\frac{1}{2}$ GH ; and since $\frac{1}{2}$ CH is equal to EC, and $\frac{1}{2}$ GH equal to $\frac{1}{2}$ FD=ED, therefore AH : IH :: EC : ED. Now AH is the sum, and IH the difference of the sides ; also EC is the tangent of half the sum, and ED the tangent of half the difference of the two angles at the base ; consequently, in any triangle, as the sum of the sides is to their difference, so is the tangent of half the sum of the angles at the base to the tangent of half their difference.

THEOREM III. If to half the sum of two quantities be added half their difference, the sum will be the greater of them ; and if from half their sum be subtracted half their difference, the remainder will be the least of them. Suppose the greater quantity to be $x=8$, and the lesser $z=6$; then is their sum 14, and difference 2 :

wherefore, adding $\frac{14}{2}=7$ to $\frac{2}{2}=1$, we

get 8 the greatest of the two quantities :

and, in the same manner, $\frac{14}{2}-\frac{2}{2}=7-$

$1=6$, the least of the two quantities.

THEOR. IV. In any right-lined triangle, ABD (*ibid.* n° 3.) the base AD is to the sum of the sides AB and BD, as the difference of the sides is to the difference of the segments of the base made by the perpendicular BE, *viz.* the difference between AE ED.

DEMON. Produce DB till BG be equal to BA the lesser leg ; and on B as a centre, with the distance BA or BG, describe the circle AGHF, which will cut BD and AD in the points H and F : then it is plain GD is the sum, and HD the difference of the sides ; also since AD is equal to EF, therefore FD is the difference of the segments of the base ; but AD : CD :: HD : FD ; therefore the base is to the sum of the sides, &c. as was to be proved.

Having established these preliminary theorems, we shall now proceed to the solution of the six cases of oblique-angled plane trigonometry.

CASE I. In any oblique-angled plane triangle, two sides
 8 Q † and

and an angle opposite to one of them being given, to find the angle opposite to the other.

EXAMPLE. In the triangle ABC (*ibid.* n° 4.) suppose $AB=156$, $BC=84$, and the angle C (opposite to AB) $=56^{\circ} 30'$; required the angle A, opposite to BC.

2. *Geometrically*: Draw the line AC, and at any point of it, suppose C, make the angle $C=56^{\circ} 30'$; then take $CB=84$, and with the length of $156=AB$ taken in your compasses from the same scale of equal parts, fixing one point in B, with the other cross AC in A. Lastly, join A and B; so the triangle is constructed, and the required angle A may be measured by a line of chords.

2. *By calculation*: We have, by theor. 1. the following proportion for finding the angle A, *viz.*

$$AB : BC :: S, C : S, A.$$

| | | |
|-------------|------------------|---------|
| i. e. as AB | 156 | 2.19312 |
| To BC | 84 | 1.92428 |
| So is S, C | $56^{\circ} 30'$ | 9.92111 |
| To S, A | $26^{\circ} 41'$ | 9.65227 |

CASE II. The angles, and a side opposite to one of them, being given, to find a side opposite to another.

EXAMPLE. In the triangle HBG (*ibid.* n° 5.) suppose the angle H $46^{\circ} 15'$, and the angle B $54^{\circ} 22'$, consequently the angle G $79^{\circ} 23'$, and the leg HB 125, required HG,

Geometrically: Draw HB 125, from any line of equal parts, and make the angle H $46^{\circ} 15'$, and B $54^{\circ} 22'$, then produce the lines HG and BG till they meet one another in the point G: so the triangle is constructed, and HG is measured by taking its length in your compasses, and applying it to the same line of equal parts that HB was taken taken from.

2. *By calculation*: By the first of the preceding theorems, we have this analogy for finding HG, *viz.*

$$S, G : HB :: S, B : HG.$$

| | | |
|------------------------|------------------|---------|
| i. e. As the sine of G | $79^{\circ} 23'$ | 9.99250 |
| is to the leg HB | 125 | 2.09691 |
| so is the sine of B | $54^{\circ} 22'$ | 9.90996 |
| to the leg HG | 103.4 | 2.01437 |

CASE III. Two sides and an angle opposite to one of them given, to find the third side.

EXAMPLE. In the triangle KLM (*ibid.* n° 6.) suppose the side CL 126 equal parts, and KM 130 of these parts, and the angle L (opposite to KM) $63^{\circ} 20'$, required the side ML.

1. *Geometrically*: The construction of this case is the same with that in Case I. (there being the same things given in both,) and the leg ML may be measured by applying it to the same line of equal parts that the other two were taken from.

2. *By calculation*: The solution of this case depends upon the two preceding ones; and, first, we must find the other two angles by Case I. thus:

$$MK : S, L :: KL : S, M.$$

| | | |
|----------------------|------------------|---------|
| i. e. As the side MK | 130 | 2.11394 |
| To the sine of L | $63^{\circ} 20'$ | 9.95116 |
| So is the side KL | 126 | 2.10037 |
| To the sine of M | $60^{\circ} 1'$ | 9.93759 |

Then by Case II. we have the required leg ML, thus:

$$S, L : S, K :: MK : ML.$$

| | | |
|------------------------|------------------|---------|
| i. e. As the sine of L | $63^{\circ} 20'$ | 9.95116 |
| To the sine of K | $53^{\circ} 39'$ | 9.90602 |

So is KM

130 2.11394

To ML

117.2 2.06850

CASE IV: Two sides and the contained angle being given, to find the other two angles.

EXAMPLE: In the triangle ACD (*ibid.* n° 7.) suppose $AC=103$, $AD=126$, and the angle $A=54^{\circ} 30'$; required the angles C and D.

1. *Geometrically*: Draw $AD=126$, and make the angle $A=54^{\circ} 30'$; then set off 103 equal parts from A to C: lastly, join C and D; and so the triangle is constructed, and the angles C and D may be measured by a line of chords.

2. *By calculation*: The solution of this case depends upon the second and third of the preceding theorems; and first we must find the sum and difference of the sides, and half the sum of the unknown angles, thus:

| | |
|---|------------------|
| The leg AD is | 126 |
| The leg AC is | 103. |
| Their sum is | 229 |
| And their difference is | 23 |
| The sum of the three angles A, D, and C, is | 180° |
| The angle A is | $54^{\circ} 30'$ |

So the sum of the angles C and D will be $125^{\circ} 30'$
 And half their sum is $62^{\circ} 45'$
 Then by theor. 2. we have the following proportion, *viz.*
 As the sum of the sides AD and AC $=229$ 2.35984
 To their difference 23 1.36173
 So is the tangent of half the sum of the unknown angles C and D } $62^{\circ} 45'$ 10.28816

To tang. of half their difference $11^{\circ} 2'$ 9.29005
 Now having half the sum and half the difference of the two unknown angles C and D, we find the quantity of each of them by theorem 3. thus:

To half the sum of the angles C and D, *viz.* $62^{\circ} 45'$
 Add half their difference, *viz.* $11^{\circ} 02'$

And the sum is the greater angle C $73^{\circ} 47'$

Again from half their sum, *viz.* $62^{\circ} 45'$
 Take half their difference, *viz.* $11^{\circ} 02'$

And there will remain the lesser angle D $=51^{\circ} 43'$

N. B. The greater angle is always that subtended by the greater side; thus, in the present case, the greater angle C, is subtended by the greater side AD; and the lesser angle D is subtended by the lesser side AC.

CASE V. Two sides and the contained angle being given, to find the third side.

EXAMPLE. In the triangle BCD (*ibid.* n° 8.) suppose $BC=154$, $BD=133$, and the angle $B=56^{\circ} 03'$; required the side CD.

1. *Geometrically*: The construction of this case is the same with that of the last, and the length of DC is found by taking its length in your compasses, and applying it to the same line of equal parts that the two legs were taken from.

2. *By calculation*: The solution of this case depends upon the second and fourth; and first we must find the angles by the last case; thus:

As the sum of the sides BD and BC 287 2.45788
 Is

Is to their difference 21 1.32222
 So is the tangent of half the sum of } 61° 58' 10.27372
 the angles D and C
 To the tangent of half their difference 7° 50' 9.13806
 So by theorem 3. we have the angles D and C thus:
 To half the sum of the angles D and C 61° 58'
 Add half their difference 7° 50'

And the sum is the greater angle D 69° 48'
 Also, from half the sum 61° 58'
 Take half the difference 7° 50'

And there remains the lesser angle C 54° 08'
 Then by Case II. we have the following analogy for finding DC the leg required, viz.

S. C : B D :: S, B : D C.

i. e. As the sine of C 54° 08' 9.90869
 To BD 133 2.12385
 So is the sine of B 56° 03' 9.91883
 To DC 136.2 2.13399

CASE VI. Three sides being given, to find the angles.
 EXAMPLE: In the triangle ABC (*ibid.* n° 9.) suppose AB=156, AC=185.7, and BC=84; required the angles A, B, and C.

I. *Geometrically*: Make AC=185.7 from any line of equal parts; and from the same line taking 156=AB in your compasses, fix one foot of them in A, and with another sweep an arch; then take 84=BC in your compasses, and fixing one foot in C, with the other sweep an arch, which will cross the former in B: lastly, join the points B and A, and B and C; so the triangle will be constructed, and the angles may be measured by a line of chords.

II. *By calculation*: Let fall the perpendicular, B D, from the vertex B, upon the base AC; which will divide the base into two segments AD and DC, the lengths whereof may be found by theorem 4. thus:

As the base AC 185.7 2.26893
 To the sum of the sides AB and BC 240 2.38031
 So is the difference of the sides 72 1.85733

To the diff. of the segments of the base 93 1.96871
 And having the sum of the segments, viz. the whole base, and their difference, we find the segments themselves, by theorem 3. thus:

To half the sum of the segments 92.8
 And half their difference 46.5

And the sum is the greater segment AD 139.3
 Also from half the sum of the segment 92.8
 Take half their difference 46.5

The remainder is the lesser segment DC 46.3
 Now the triangle ABC is divided, by the perpendicular BD, into two right-angled triangles, ADB and DBC; in the first of which are given the hypotenuse AB=156, and the base AD=139.3, to find the oblique angles, for which we have (by Case V. of rectangular trigonometry) the following analogy, viz.

As AB 156 2.19312
 To AD 139.3 2.14395
 So is the radius 90° 10.00000

To the co-sine of the angle A 26° 40' 9.95083

Also the angle C is found by the same case, thus:

As BC 84 1.92428
 To CD 46.3 1.66558
 So is the radius 90° 10.00000

To the co-sine of C 56° 30' 9.74130
 Having found the two angles A and C, we have the third, B, by taking the sum of the other two from 180, thus:
 The sum of all the three angles is 180°
 The sum of A and C is 83° 10'

The angle B is 96° 50'
 All the proportions used for the solutions of the several cases in plain trigonometry, may be performed by the scale and compass. On the scale there are several logarithmic lines, viz. one of numbers, another of sines, and one of tangents, &c.

And the way of working a proportion by these is this, viz. extend your compasses from the first term of your proportion, found on the scale, to the second; and with that extent, fixing one foot in the third term, the other will reach the fourth term required.

SPHERICAL TRIGONOMETRY.

SPHERICAL TRIGONOMETRY is the art whereby, from three given parts of a spherical triangle, we discover the rest; and, like plane trigonometry, is either right-angled, or oblique-angled. But before we give the analogies for the solution of the several cases in either, it will be proper to premise the following theorems.

THEOREM I. In all right-angled spherical triangles, the sine of the hypotenuse: radius :: sine of a leg: sine of its opposite angle. And the sine of a leg: radius :: tangent of the other leg: tangent of its opposite angle.

DEMONSTRATION. Let E D A F G (*ibid.* fig. 3.) represent the eighth part of a sphere, where the quadrantal planes E D F G, E D B C, are both perpendicular to the quadrantal plane A D F B; and the quadrantal plane A D G C is perpendicular to the plane E D F G; and the spherical triangle ABC is right-angled at B, where CA is the hypotenuse, and BA, BC, are the legs.

To the arches GF, CB, draw the tangents H F, O B, and the sines GM CI on the radii DF DB; also draw BL the sine of the arch AB, and CK the sine of AC; and then join IK and OL. Now HF, OB, GM, CI, are all perpendicular to the plane A D F B. And HD, GK, OL, lie all in the same plane ADGC. Also FD, IK, BL, lie all in the same plane ADGC. Therefore, the right-angled triangles HFD, CIK, ODL, having the equal angles HDF, CKI, OLB, are similar. And CK:DG :: CI:GM; that is, as the sine of the hypotenuse: rad. :: sine of a leg: sine of its opposite angle. For GM is the sine of the arc GF, which measures the angle CAB. Also, LB:DF :: BO:FH; that is, as the sine of a leg: radius :: tangent of the other leg: tangent of its opposite angle. Q. E. D.

Hence it follows, that the sines of the angles of any oblique spherical triangle ACD (*ibid.* n° 2.) are to one another, directly, as the sines of the opposite sides. Hence it also follows, that, in right-angled spherical triangles, having the same perpendicular, the sines of the bases will be to each other, inversely, as the tangents of the angles at the bases.

THEOREM II. In any right-angled spherical triangle ABC (*ibid.* n^o 3.) it will be, As radius is to the co-sine of one leg, so is the co-sine of the other leg to the co-sine of the hypothenuse.

Hence, if two right angled spherical triangles ABC, CBD (*ibid.* n^o 2) have the same perpendicular BC, the co-sines of their hypothenuses will be to each other, directly, as the co-sines of their bases.

THEOREM III. In any spherical triangle it will be, As radius is to the sine of either angle, so is the co-sine of the adjacent leg to the co-sine of the opposite angle.

Hence, in right-angled spherical triangles, having the same perpendicular, the co-sines of the angles at the base will be to each other, directly, as the sines of the vertical angles.

THEOREM IV. In any right-angled spherical triangle it will be, As radius is to the co-sine of the hypothenuse, so is the tangent of either angle to the co-tangent of the other angle.

As the sum of the sines of two unequal arches is to their difference, so is the tangent of half the sum of those arches to the tangent of half their difference: and, as the sum of the co-sines is to their difference, so is the co-tangent of half the sum of the arches to the tangent of half the difference of the same arches.

THEOREM V. In any spherical triangle ABC (*ibid.* n^o 4. and 5.) It will be, as the co-tangent of half the sum of half their difference, so is the co-tangent of half the base to the tangent of the distance (DE) of the perpendicular from the middle of the base.

Since the last proportion, by permutation, becomes co-tang. $\frac{AC+BC}{2}$: co-tang. AE :: tang. $\frac{AC-BC}{2}$: tang.

DE, and as the tangents of any two arches are, inversely, as their co-tangents; it follows, therefore, that tang. AE : tang. $\frac{AC+BC}{2}$:: tang. $\frac{AC-BC}{2}$: tang. DE; or, that

the tangent of half the base is to the tangent of half the sum of the sides, as the tangent of half the difference of the sides to the tangent of the distance of the perpendicular from the middle of the base.

THEOREM VI. In any spherical triangle ABC (*ibid.* n^o 4) it will be, as the co-tangent of half the sum of the angles at the base, is to the tangent of half their difference, so is the tangent of half the vertical angle to the tangent of the angle which the perpendicular CD makes with the line CF bisecting the vertical angle.

The Solution of the Cases of right-angled Spherical Triangles, (*ibid.* n^o 3.)

| Case | Given | Sought | Solution |
|------|-------------------------------------|----------------------|--|
| 1 | The hyp. AC and one angle A | The opposite leg BC | As radius : sine hyp. AC :: sine A : sine BC (by the former part of theo. 1.) |
| 2 | The hyp. AC and one angle A | The adjacent leg AB | As radius : co-sine of A :: tang. A C. tang. AB by the latter part of theo. 1. |
| 3 | The hyp. AC and one angle A | The other angle C | As radius : co-sine of AC :: tang. A : co-tang. C (by theorem 4.) |
| 4 | The hyp. AC and one leg AB | The other leg BC | As co-sine AB : radius :: co-sine AC : co-sine BC (by theorem 2.) |
| 5 | The hyp. AC and one leg AB | The opposite angle C | As sine AC : radius :: sine AB : sine C (by the former part of theorem 1.) |
| 6 | The hyp. AC and one leg AB | The adjacent angle A | As tang. AC : tang. AB :: radius : co-sine A (by theorem 1.) |
| 7 | One leg AB and the adjacent angle A | The other leg BC | As radius : sine AB :: tangent A : tangent BC (by theorem 4.) |
| 8 | One leg AB and the adjacent angle A | The opposite angle C | As radius : sine A :: co-sine of AB : co-sine of C (by theorem 3.) |
| 9 | One leg AB and the adjacent angle A | The hyp. AC | As co-sine of A : radius :: tang. AB : tang. AC (by theorem 1.) |
| 10 | One leg BC and the opposite angle A | The other leg AB | As tang. A : tang. BC :: radius : sine AB (by theorem 4.) |
| 11 | One leg BC and the opposite angle A | The adjacent angle C | As co-sine BC : radius :: co-sine of A : sin. C (by theorem 3.) |
| 12 | One leg BC and the opposite angle A | The hyp. AC | As sin. A : sin. BC :: radius : sin. AC (by theorem 1.) |
| 13 | Both legs AB and BC | The hyp. AC | As radius : co-sine AB :: co-sine BC : co-sine AC (by theorem 2.) |
| 14 | Both legs AB and BC | An angle, suppose A | As sine AB : radius :: tang. BC : tang. A (by theorem 4.) |
| 15 | Both angles A and C | A leg, suppose AB | As sine A : co-sine C :: radius : co-sine AB (by theorem 3.) |
| 16 | Both angles A and C | The hyp. AC | As tan. A : co-tang. C :: radius : co-sine AC (by theorem 4.) |

Note, The 10th, 11th, and 12th cases are ambiguous; since it cannot be determined by the data, whether A, B, C, and A C, be greater or less than 90 degrees each.

The

The Solution of the Cases of oblique spherical Triangles, (*ibid.* n^o 4. and 5.)

| Case | Given | Sought | Solution |
|------|---|---------------------------------------|--|
| 1 | Two sides AC, BC, and an angle A opposite to one of them. | The angle B opposite to the other | As sine BC : sine A :: sine AC : sine B (by theor. 1.) Note, this case is ambiguous when BC is less than AC; since it cannot be determined from the data whether B be acute or obtuse. |
| 2 | Two sides AC, BC, and an angle A opposite to one of them. | The included angle ACB | Upon AB produced (if need be) let fall the perpendicular CD : then (by theor. 4.) rad. : co-sine AC :: tang. A : co-tang. ACD; but (by theor. 1.) as tang. BC : tang. AC :: co-sine ACD : co-sine BCD. Whence $\angle ACB = \angle ACD \pm \angle BCD$ is known. |
| 3 | Two sides AC, BC, and an angle opposite to one of them | The other side AB | As rad. : co-sine A :: tang. AC : tang. AD (by theor. 1.) and (by theor. 2.) as co-sine AC : co-sine BC :: co-sine AD : co-sine BD. Note, this and the last case are both ambiguous when the first is so. |
| 4 | Two sides AC, AB, and the included angle A | The other side BC | As rad. : co-sine A :: tang. AC : tan. AB (by theor. 1.) whence AD is also known : then (by theor. 2.) as co-sine AD : co-sine BD :: co-sine AC : co-sine BC. |
| 5 | Two sides AC, AB, and the included angle A | Either of the other angles, suppose B | As rad. : co-sine A :: tang. AC : tan. AD (by theorem 1.) whence BD is known : then (by theor. 4.) is sine BD : sine AD :: tan. A : tan. B. |
| 6 | Two angles A, ACB, and the side AC betwixt them | The other angle B | As rad. : co-sine AB :: tang. A : co-tang. ACD (by theor. 4.) whence BCD is also known : then (by theor. 3.) as sine ACD : sine BCD :: co-sine A : co-sine B. |
| 7 | Two angles A, ACB, and the side AC betwixt them | Either of the other sides suppose BC | As rad. : co-sine AC :: tang. A : co-tang. ACD (by theo. 4) whence BCD is also known : then, as co-sine BCD : co-sine ACD :: tang. AC : tang. BC (by theor. 1.) |
| 8 | Two angles A, B, and a side AC opposite to one of them | The side BC opposite the other | As sine B : sine AC :: sine A : sine BC (by theorem 1.) |
| 9 | Two angles A, B, and a side AC opposite to one of them | The side AB betwixt them | As rad. : co-sine A :: tang. AC : tan. AD (by theor. 1.) and as : tang. B : tang. A :: sine AD : sine BD (by theor. 4.) whence AB is also known. |
| 10 | Two angles A, B, and a side AC opposite to one of them | The other angle ACB | As rad. : co-sine AC :: tang. A : co-tang. ACD (by theor. 4.) and as co-sine A : co-sine B :: sine ACD : sine BCD (by theor. 3.) whence ACB is also known. |

T R I

TRINGA, in ornithology, a genus of birds belonging to the order of grallæ. The beak is somewhat cylindrical, and as long as the head; the nostrils are ^{large}; and there are four toes on the feet, the hind one coming of one joint, and elevated above the ground. There are 23 species, principally distinguished by their colour.

TRINGLE, in architecture, a name common to several little square members or ornaments, as reglets, listels, and plat-bands. It is more particularly used for a little member fixed exactly over every triglyph, under the plat-band of the architrave, from whence the guttæ or pendant drops hang down.

TRINIDAD, or **TRINITY-ISLAND**, is situated in the Atlantic or American ocean, between 60° and 62° of west longitude, and between 9° and 11° of north latitude; it is about ninety miles long, and sixty broad.

TRINIDAD, a port-town of Mexico, in America, situated in the province of Guatimala, an hundred and twenty miles south-east of the city of Guatimala: W. long. 94°, N. lat. 13°.

TRINITARIANS, those who believe in the Trinity; those who do not believe therein, being called antitrinitarians.

Trinitarians also denote an order of relig. instituted at Rome in the year 1198, under the pontificate of Innocent III. the founders whereof were John de Matha, and Felix de Valois. His holiness gave them permission to establish this order for the deliverance of captives, who groaned under the tyranny of the infidels: he gave them, as a habit, a white gown ornamented with a red and blue cross. After the death of the two founders, pope Honorius III. continued the order, and their rule was approved by his successor Clement IV. in 1267. At first they were not permitted to eat flesh, and, when they travelled, were to ride only upon asses. But their rule was corrected and mitigated by the bishop of Paris, and the abbots of St. Victor and St. Genevieve, who allowed them to eat any kind of food, and to use horses. This

T R I

order possesses about two hundred and fifty convents in thirteen different provinces: six of which are in France; namely, France, Normandy, Picardy, Champagne, Languedoc, and Provence; three in Spain, viz. New Castile, Old Castile, and Arragon; one is in Italy, and one in Portugal. There was formerly the province of England, where this order had forty-three houses; that of Scotland, where it had nine; and that of Ireland, where it had fifty-two; besides a great number of monasteries in Saxony, Hungary, Bohemia, and other countries. The convent of Cerroir in France is head of the order.

TRINITY, in theology, the ineffable mystery of three persons in one God; Father, Son, and Holy Spirit.

TRINITY SUNDAY, a festival observed on the Sunday next after Whitsunday, in honour of the holy Trinity. The observation of this festival was first enjoined in the council of Arles, anno 1260.

Fraternity of the TRINITY, a religious society instituted at Rome by St. Philip Neri, in 1538. These religious were appointed to take care of the pilgrims who came to visit the tombs of St. Peter and St. Paul. The society originally consisted of only fifteen religious, who assembled on the first Sunday of every month, in the church of St. Saviour del Campo, to hear the exhortations of the founder; after whose death pope Paul IV. gave the fraternity the church of St. Benedict, near which they have since built a large hospital, for the reception of pilgrims. The fraternity is one of the most considerable in Rome, and most of the nobility of both sexes have been members thereof.

TRIO, in music, a part of a concert wherein three persons sing; or more properly a musical composition consisting of three parts.

TRIONES, in astronomy, a sort of constellation or assemblage of several stars in the ursa minor, commonly called Charles's wain.

TRIOPTERIS, in botany, a genus of the decandria tri-gynia

Fig. 1. Rectangular TRIGONOMETRY

Plate CLIX.

Fig. 2. Oblique angled TRIGONOMETRY

Fig. 3. Spherical TRIGONOMETRY

gynia class. The calix consists of six segments; and there are three seeds, with a double membranous wing. There is but one species, a native of Jamaica.

TRIP, a sea-term. A ship is said to bear her top-sails a-trip, when she carries them hoisted up to the highest.

TRIPARTITE, something divided into three parts, or made by three parties, as indenture tripartite, &c.

TRIPARTITION, a division by three, or the taking the third part of any number or quantity.

TRIPHTHONG, in grammar, an assemblage or concurrence of three vowels in the same syllable, as *que*.

TRIPLE, in music, is one of the species of measure or time. See **MUSIC**.

TRIPOD, in antiquity, a famed sacred seat or stool, supported by three feet, whereon the priests and sibyls were placed to render oracles. It was on the tripod that the gods were said to inspire the Pythians with that divine fury and enthusiasm wherewith they were seized at the delivery of their predictions.

TRIPOLI, a state of Africa, which including Barca, is bounded by the Mediterranean-sea on the north, by Egypt on the east, by Nubia and Bildulgerid on the south, and by Tunis on the west: extending along the shore of the Mediterranean from the north-west to the south-east about a thousand miles, but scarce two hundred miles broad in any place. The city of Tripoli, being the capital of this state, is surrounded with a wall and other fortifications: E. long. $14^{\circ} 30'$, N. lat. $33^{\circ} 30'$.

TRIQUETROUS, among botanists, expresses a fruit or leaf that has three sides or faces all flat.

TRIEMIS, in antiquity, a gally with three ranks of oars on a side.

TRISMEGISTUS, an epithet or surname given to one of the two Hermeses, or Mercuries, kings of Thebes in Egypt, who is said to be contemporary with Moses.

TRISPASTON, in mechanics, a machine with three pulleys, or an assemblage of three pulleys for raising of great weights.

TRISYLLABLE, in grammar, a word consisting of three syllables.

TRITICUM, in botany, a genus of the triandria digynia class. The calix consists of two sessile valves, containing three flowers. There are eleven species, only three of them natives of Britain, *viz.* the repens, or couch-grass; the canium, or bearded wheat-grass; and the junceum, or sea wheat-grass. For the culture of wheat, see **AGRICULTURE**, p. 60.

TRITON, in zoology, a genus belonging to the order of vermes mollusca. The body is oblong; the tongue is spiral; it has 12 tentacula, six on each side, the hindmost ones having claws like a crab. There is but one species, found in holes of rocks about the sea-shore.

TRITON, a sea demi-god, held by the ancients to be an officer or trumpeter of Neptune, attending on him, and carrying his orders and commands from sea to sea.

TRITURATION, the act of reducing a solid body into a subtil powder; called also levigation and pulverization.

TRIUMFETTA, in botany, a genus of the dodecandria monogynia class. The corolla consists of five petals, and the calix of five leaves: and the capsule is hairy, and opens in four parts. There are two species, both natives of India.

TRIUMPH, in Roman antiquity, a public and solemn ho-

nour conferred by the Romans on a victorious general: by allowing him a magnificent entry into the city.

The greater triumph, called also *curulis*, or simply the triumph, was decreed by the senate to a general, upon the conquering of a province, or gaining a signal victory. The day appointed for the ceremony being arrived, scaffolds were erected in the forum and circus, and all the other parts of the city, where they could best behold the pomp: the senate went to meet the conqueror without the gate called Capena or Triumphalis, and marched back in order to the capitol; the ways being cleared and cleansed by a number of officers and tipstiffs, who drove away such as thronged the passage, or straggled up and down. The general was clad in a rich purple robe, interwoven with figures of gold, setting forth his great exploits; his buskins were beset with pearl; and he wore a crown, which at first was only laurel, but afterwards gold; in one hand he bore a branch of laurel, and in the other a truncheon. He was drawn in a magnificent chariot, adorned with ivory and plates of gold, drawn usually by two white horses; though sometimes by other animals, as that of Pompey, when he triumphed over Africa, by elephants; that of Marc Antony, by lions; that of Hellogabalus, by tigers; that of Aurelian, by deer, &c. His children were at his feet, and sometimes on the chariot-horses. The procession was led up by the musicians, who played triumphal pieces, in praise of the general: these were followed by young men, who led the victims to the sacrifice, with their horns gilded, and their heads adorned with ribbands and garlands; next came the carts and waggons, loaded with all the spoils taken from the enemy, with their horses, chariots, &c. these were followed by the kings, princes, and generals, who had been taken captives, laden with chains: after these appeared the triumphal chariot, before which, as it passed, they all along strewed flowers, and the people, with loud acclamations, called out *Io triumphe!* The chariot was followed by the senate, clad in white robes; and the senate by such citizens as had been set at liberty or ransomed: and the procession was closed by the priests and their officers and utensils, with a white ox led along, for the chief victim. In this order they proceeded through the triumphal gate, along the *via sacra*, to the capitol, where the victims were slain. In the mean time all the temples were open, and all the altars loaded with offerings and incense; games and combats were celebrated in the public places, and rejoicings appeared every where.

TRIUMVIR, one of three persons who govern absolutely, and with equal authority, in a state. It is chiefly applied to the Roman government: Caesar, Pompey, and Crassus were the first triumvirs, who divided the government amongst them. There were also other officers, called triumvirs; as the *triumviri trestviri capitales*, who were the keepers of the public goal: they had the office of punishing malefactors; for which purpose they kept eight lictors under them.

TRIUMVIRATE, an absolute government, administered by three persons with equal authority. See the preceding article.

TROCHANTER, in anatomy. See **ANATOMY**, p. 182.

TROCHE, in pharmacy, a sort of medicine, made of glutinous substances, into little cakes, and afterwards excised.

TROCHÆUS,

TROCHÆUS, in the Greek and Latin poetry, a foot consisting of two syllables, the first long, and the second short.

TROCHILUS, in ornithology, a genus belonging to the order of picæ. The beak is subulated and thread-shaped, with a tubular apex, and longer than the head, the superior mandible sheathing the inferior; the tongue is thread-shaped; and the feet are fitted for walking. This genus comprehends all the humming birds, which are the smallest of birds, and are distinguished by their colour and the shape of their bills.

TROCHLEA, one of the mechanical powers, usually called a pulley. See **MECHANICS**.

TROCHLEARES, in anatomy. See **ANATOMY**, p. 290.

TROGLODYTES, in the ancient geography, a people of Æthiopia, said to have lived in caves under ground. Pœm. Mela gives a strange account of the Troglodytes: he says, they did not so properly speak as shriek, and that they lived on serpents.

TROJA, or **TROJAN GAMES**, were games said to be instituted by Ascanius, son of Æneas, and afterwards kept up by the Romans with great solemnity. They were celebrated by companies of boys, neatly dressed, and furnished with little arms and weapons, who mustered in the public circus. They were chosen, for the most part, out of the noblest families of Rome, and the captain of them had the honourable title of princeps juventutis; being sometimes next heir to the empire, and seldom less than the son of a principal senator.

TROIS RIVIERES, a town of North America, in the province of Canada, situated on the river of St. Laurence, fifty miles south of Quebec: W. long. 75°, and N. lat. 46° 45'.

TRONAGE, an ancient customary toll, paid for weighing of wool. This word is particularly mentioned in a charter granted to the mayor and citizens of London; in which city there is an officer called tronator, whose business it is to weigh the wool that is brought thither.

TRONCONNEE, in heraldry, denotes a cross, or other thing, cut in pieces and dismembered, yet so as all the pieces keep up the form of a cross, though set at a small distance from one another.

TROOP, a small body of horse or dragoons, about fifty or sixty, sometimes more, sometimes less; commanded by a captain. Each troop, besides a captain, has a lieutenant, cornet, quarter-master, and three corporals, who are the lowest officers of a troop.

TROPEOLUM, in botany, a genus of the octandria monogynia class. The calix consists of one calcarated leaf; and the corolla of five unequal petals; and there are three dry berries. The species are three, all natives of Peru.

TROPE, in rhetoric, a kind of figure of speech, whereby a word is removed from its first and natural signification, and applied with advantage to another thing, which it does not originally mean; but only stands for it, as it has a relation to, or connection with it: as in this sentence, *God is my rock*. Here the trope lies in the word *rock*, which being firm and immovable, excites in our minds the notion of God's unfailling power, and the steady support which good men receive from their dependence upon him.

TROPHY, among the ancients, a pile or heap of arms of

a vanquished enemy, raised by the conqueror in the most eminent part of the field of battle.

TROPICS, in astronomy. See **ASTRONOMY**, p. 469.

TROUT, in ichthyology. See **SALMO**.

TRUFFLES. See **LYCOPERDON**.

TRUMPET, a musical instrument, the most noble of all portable ones of the wind kind, used chiefly in war among the cavalry, to direct them in the service.

TRUNCATED, in general, is an appellation given to such things as have, or seem to have, their points cut off: thus we say, a truncated cone, pyramid, leaf, &c.

TRUNCHEON, a short staff, or battoon, used by kings, generals, and great officers, as a mark of their command.

TRUNDLE, a sort of carriage with low wheels, whereon heavy and cumbersome burdens are drawn.

TRUNK, among botanists, denotes the stem, or body, of a tree; or, that part between the ground and the place where it divides into branches.

TRUNNIONS, or **TRUNIONS of a piece of ordnance**, are those knobs or bunches of the gun's metal, which bear her up on the cheeks of the carriage.

TRUSS, a bundle, or certain quantity of hay, straw, &c.

A truss of hay is to contain fifty-six pounds, or half an hundred weight; thirty-six trusses make a load.

TRUSS is also used for a sort of bandage or ligature, made of steel, or the like matter, wherewith to keep up the parts in those who have hernias or ruptures.

TRUSTEE, one who has an estate, or money, put or trusted in his hands for the use of another.

TRUTH, a term used in opposition to falsehood, and applied to propositions which answer, or accord, to the nature and reality of the thing whereof something is affirmed, or denied.

TUB, in commerce, denotes an indeterminate quantity or measure: thus, a tub of tea contains about sixty pounds; and a tub of camphor from fifty-six to eighty pounds.

TUBE, in general, pipe, conduit, or canal; a cylinder hollow within, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage or conveyance through.

TUBERCLE, in botany, a kind of round turgid root, in form of a knob or turnip.

The plants which produce such roots are hence denominated tuberose, or tuberous, plants.

TUBERCLES, among physicians, denote little tumours which suppurate and discharge pus, and are often found in the lungs, especially of consumptive persons.

TUBIPORA, a genus of submarine plants, belonging to the cryptogamia class, of the hardness of coral, and consisting of cylindrical tubes rising from a thin crust of the same sort of matter with themselves.

TUBULI LACTIFERI, in anatomy. See **ANATOMY**, p. 277.

TUCUMAN, the south-west division of the province of La Plata, or Paraguay, in South America.

TULIPA, in botany, a genus of the hexandria monogynia class. The corolla is bell shaped, and consists of six petals; it has no stylos. There are three species, none of them natives of Britain.

TUMEFACATION, the act of swelling or rising into a tumour.

TUMOUR, in medicine and surgery, a preternatural rising

rising or eminence on any part of the body. See SURGERY, p. 663.

TUN, a large vessel or cask of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandize, for convenience of carriage; as brandy, oil, sugar, skins, hats, &c. This word is also used for certain vessels of extraordinary bigness, serving to keep wine in for several years.

TUN is also a certain weight whereby the burden of ships, &c. are esteemed.

TUNBRIDGE, a town of Kent, situated thirty-three miles west of Canterbury, much resorted to on account of its excellent waters.

TUNICA, a kind of waistcoat, or under garment, in use amongst the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics, whence Horace calls them *populus tunicatus*.

TUNICA, in anatomy, is applied to the membranes which invest the vessels, and divides others of the left solid parts of the body; thus the intestines are formed of five tunics, or coats.

TUNIS, the capital of the kingdom of Tunis, thirty miles south of Carthage ruins, 300 miles east of Algiers, and 120 south-west of Trapano, in Sicily; a populous city, about three miles in circumference: E. long. 10° N. lat. 36° 20'. The kingdom of Tunis is situated on the coast of Barbary, in Africa, being bounded by the Mediterranean sea on the north. It extends 200 miles in length from east to west, along the shore of the Mediterranean; the breadth is very unequal.

TUNNAGE is used for a custom or impost, payable to the crown, for goods and merchandize imported or exported, and is to be paid after a certain rate for every tun thereof. This duty, as well as that of poundage, was first granted for life to king Charles II. and has been continued in the same manner to his royal successors, down to his present majesty king George III.

TURBAN, the head-dress of most of the eastern nations. It consists of two parts, a cap, and a shawl of fine linen or taffety, artfully wound in divers plaits about the cap. The cap has no brim, is pretty flat, though roundish at top, and quilted with cotton, but does not cover the ears. There is a good deal of art in giving the turban a fine air, and the making of them is a particular trade. The shawl of the Turks turban is white linen; that of the Persians red woollen. These are the distinguishing marks of their different religions. Sophi, king of Persia, being of the sect of Ali, was the first who assumed the last colour, to distinguish himself from the Turks, who are of the sect of Omar; and whom the Persians esteem heretics.

TURBINATED, is a term applied by naturalists, to shells which are spiral, or wreathed, conically, from a larger basis to a kind of apex.

TURBITH, or **TURPETH-ROOT**, in the materia medica, the cortical part of the root of an Indian convolvulus, brought to us in oblong pieces, of a brown or ash-colour on the outside, and whitish within: the bell is ponderous, not wrinkled, easy to break, and discovering a large quantity of resinous matter to the eye: its taste is at first sweetish; when chewed for a little time, it becomes acid,

pungent, and nauseous. This root is a cathartic, not of the safest, or most certain kind.

TURBITH-MINERAL. See CHEMISTRY, p. 139.

TURBO, in zoology, a genus of insects belonging to the order of vermes testacea. This is an animal of the snail kind; the shell consists of one spiral solid valve; and the aperture is orbicular. There are 49 species, distinguished by peculiarities in their shells.

TURBOT, in ichthyology. See **PLEURONECTES**.

TURCICA TERRA **TURKY-EARTH**, in the materia medica, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and used by the Turks as a tuforific and alstringent, and famous among them in peltential diseases.

TURCOISE, in natural history, an ore of copper.

There are, indeed, two kinds of turcois; the one a true and genuine ore of copper; the other the bones of animals tinged to a beautiful blue colour, by having been buried in places where copper-ore has been near them.

TURCOMANIA, a province of Asiatic Turkey, bounded by Persia on the east, and answers to the ancient Armenia; its capital is Erzerum.

TURDUS, in ornithology, a genus belonging to the order of passeress. The bill is somewhat cylindrical and cultrated; the nostrils are naked; the faux is ciliated; and the tongue is lacerated. There are 28 species, principally distinguished by their colour.

TURENNE, a town of Guienne, in France: E. long. 1° 20', and N. lat. 45° 7'.

TURGESCE, among physicians, denotes a swelling, or growing bloated.

TURIN, the capital of Piedmont, in Italy, and of the king of Sardinia's dominions, is situated at the confluence of the rivers Po and Doria, 100 miles south-west of Milan: E. long. 7° 16', and N. lat. 44° 50'.

TURIONES, among herbalists, denotes the first young tender shoots which plants annually put forth.

TURKEY, in ornithology. See **MELEAGRIS**.

TURKEY, a very extensive empire, comprehending some of the richest countries in Europe, Asia, and Africa.

Turky in Europe, comprehends Romania, Bulgaria, Servia, Bosnia, Ragusa, Wallachia, Moldavia, Bessarabia, Budzac, Crim, and little Tartary, with Albania, Epirus, Macedonia, Theffaly, and all the ancient Greece, with its numerous islands. See **ROMANIA**, &c.

Turky in Asia, comprehends Natolia, Diarbeck, Syria, Turcomania, and part of Georgia and Arabia.

And Turkey in Africa, comprehends the fruitful and extensive country of Egypt.

TURMERIC, in the materia medica, the root of a plant, called by botanists *curcuma*. See **CURCUMA**.

TURNEP, in botany, a species of brassica. For the culture of them, see **AGRICULTURE**, p. 67.

TURNERA, in botany, a genus of the pentandria trigynia class. The calix is funnel-shaped, and consists of five segments; there are five petals inserted into the calix; the stigmata are divided into many parts; and the capsule has one cell. There are three species, none of them natives of Britain.

TURNING, a branch of sculpture, being the art of fashioning hard bodies, as brass, ivory, wood, &c. into a round or oval form, in a lathe.

TURNSOLE, in botany. See *Croton*.

TURPENTINE, a transparent sort of resin, flowing either naturally or by incision from several unctuous and resinous trees, as the terebinthus, larch, pine, fir, &c.

The turpentine of Chio or Scio, which is the only genuine kind, and that which gives the denomination to all the rest, is a whitish resin, bordering a little on green, very clear, and a little odoriferous; drawn by incision from a tree called terebinthus, very common in that island, as also in Cyprus, and some parts of France and Spain.

The uses of turpentine in medicine are innumerable. It is a great vulnerary, and very detergent, and as such is prescribed in abscesses, ulcerations, &c. It promotes expectoration, and as such is prescribed in diseases of the lungs and breast; but it is most famous for clearing the urinary passages, and as such prescribed in obstructions of the reins, in gonorrhœas, &c.

Oil of TURPENTINE. There are two kinds of oil drawn from turpentine, by distillation; the first white, the second red, both esteemed as balsams proper for the cure of wounds, chilblains, &c. But they are so little used among us, that it is not easy to procure either of them.

What is commonly sold under the name of oil of turpentine, or ethereal oil, is only a distillation of the resinous juice of the tree, fresh as it is gathered. It is used with success in the cure of green wounds, as also by the painters, farriers, &c. To be good, it must be clear and pellucid as water, of a strong penetrating smell, and very inflammable.

TURRITIS, in botany, a genus of the tetradynamia siliquosa class. The pod is very long, and angular; the calix is connivent and erect; and the corolla is erect. There are two species, both natives of Britain, viz. the glabra, or great tower-mustard; and the hirsuta, or hairy tower-mustard.

TURTLE, in ichthyology. See *TESTUDO*.

TUSCAN ORDER, in architecture. See *ARCHITECTURE*, p. 351.

TUSCAN EARTH, in the materia medica, a yellowish, white, pure bole, considerably heavy, of a very smooth surface, not easily breaking between the fingers, but adhering slightly to the tongue, and melting very readily in the mouth. It is dug in many parts of Italy, particularly about Florence, where there is a stratum of it eight or ten feet thick, at the depth of five or six from the surface. It is given as a sudorific, and esteemed a great medicine in fevers, attended with diarrhœas.

TUSCANY, a duchy of Italy, encompassed by the pope's territories on the north-east and south, and bounded by the Tuscan Sea on the south-west, and by the territories of Lucca and Modena on the north-west, being 200 miles long, and almost as many broad.

TUSSILAGO, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is naked; the pappus is simple; and the scales of the calix are equal, and somewhat membranaceous. There are nine species, three of them natives of Britain, viz. the farfara, or common colt's foot; the hybrida, or long-stalked butter-bur; and the petasitis, or common butter-bur.

The common colt's foot stands recommended in coughs and other disorders of the breast and lungs.

TUTOR. See *LAW*, Tit. vii. 1, &c.

TUTTY, a recement of mixed metals, in which lapis calaminaris, or zink in its metallic form, is an ingredient, collected in the furnaces where brass is made from copper and calamine, and where the mixed metals are run. In these furnaces they place, under the roof and about the upper parts of the slides, rods of iron, and sometimes rolls of dry earth, about which the tutty is afterwards found. Therefore the tutty which we use in the shops at this time, owes its origin truly and properly to zink, which sublimes with a very small fire into a kind of flowers, and, when fused with any other metal, flies from it in abundance under this form, and also frequently takes some part of the metal, more or less, up with it. Hence it is evident, that the tutty or cadmia of the ancients, must have been wholly different from ours, as they used no zink nor any of its ores in the furnace where they collected it.

Our tutty then is a hard and heavy semimetallic recement, sometimes met with in the shops in thin flat pieces or flakes, but most abundantly in tubular cylindric pieces, resembling segments of the barks of trees pushed off from the branches without breaking; these are of different lengths and diameters. The finest tutty is that of a fine deep brown on the outside, and of a yellowish tinge within; the thickest, brightest, and most granulated; the hardest to break, and that which has least foulness among it.

Tutty is celebrated as an ophthalmic, and frequently employed as such in unguents and collyria.

TUXFORD, a market-town of Nottinghamshire, twenty miles north-east of Nottingham.

TWEED, a river of Scotland, which rises on the confines of the shire of Clydesdale, and running eastward through Tweedale, and dividing the shire of Mers from Tiviotdale and Northumberland, falls into the German sea at Berwick.

TWEEDALE, a county of Scotland, bounded by Lothian on the north, by Mers and Tiviotdale on the east, by Annandale on the south, and Clydesdale one the west.

TWEER, a city of Russia, capital of the province of Tweer, situated on the river Wolgo, ninety miles north of Moscow, in E. long. 30° 37'. N. lat. 57° 25'.

TWELFTH-DAY, the festival of the epiphany, or the manifestation of Christ to the Gentiles; so called, as being the twelfth day, exclusive, from the nativity or Christmas-day.

TWILIGHT, that light, whether in the morning before sun-rise, or in the evening after sun-set, supposed to begin and end when the least stars that can be seen by the naked eye cease, or begin to appear. By means of the atmosphere it happens, that though none of the sun's direct rays can come to us after it is set, yet we still enjoy its reflected light for some time, and night approaches by degrees. For after the sun is hid from our eyes, the upper part of our atmosphere remains for some time exposed to its rays, and from thence the whole is illuminated by reflection.

TWINS, two young ones delivered at a birth, by an animal which ordinarily brings forth but one.

TYGER, or TIGER, in zoology. See *LEO*.

TYLE, or TILE, in building, a sort of thin laminated brick, used on the roofs of houses; or more properly a kind

kind of fat clayey earth, kneaded and moulded, of a just thickness, dried and burnt in a kiln like brick, and used in the covering and paving of houses.

TYMPAN of an arch, is a triangular space or table in the corners or sides of an arch, usually hollowed, and enriched sometimes with branches of laurel, olive-tree, or oak, or with trophies, &c. sometimes with flying figures, as fame, &c. or sitting figures, as the cardinal virtues.

TYMPAN, among printers, a double frame belonging to the press, covered with parchment, on which the blank sheets are laid in order to be printed off. See **PRINTING-PRESS**.

TYMPANUM, in mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed flaves, for the more easy turning the axis, in order to raise a weight required. The tympanum is much the same with the peritrochium, but that the cylinder of the axis of the peritrochium is much shorter, and less than the cylinder of the tympanum.

TYMPANUM, in anatomy. See **ANATOMY**, p. 296.

TYMPANY, in medicine. See **MEDICINE**, p. 110.

TYPE, a copy, image, or resemblance of some model.

The word is much used among divines, to signify a symbol, sign, or figure of something to come; in which sense it is commonly used with relation to antitype, which is the thing itself, whereof the other is a type or figure.

TYPE, among letter-founders and printers, the same with letter. See **LETTER**.

TYPE is also used to denote the order observed in the intention and remission of fevers, pulses, &c.

TYPHA, in botany, a genus of the monoecia triandria class. The amenum of both male and female is cylindrical; the calix of the male consists of three leaves; and neither of them have any corolla. There are two species, both of them natives of Britain, *viz.* the latifolia, or great cat's-tail; and angustifolia, or narrow-leaved cat's-tail.

TYPHODES, in medicine, a kind of ardent or burning fever usually attending on erysipelas of any of the viscera.

TYPOGRAPHY, the art of printing. See **PRINTING**.

TYRANT, among the ancients, denoted simply a king or monarch. But the ill use several persons invested with that sacred character made of it, has altered the import of the word; and tyrant now carries with it the idea of an unjust and cruel prince, who invades the peoples liberty, and rules in a more despotic manner than the laws of nature or the country do allow of.

TYRE, a port-town of Phœnicia, in Asiatic Turkey, situated on the coast of the Levant, in E. long. 36°, N. lat. 32° 32', being anciently the capital of Phœnicia.

TYRONE, an Irish county, in the province of Ulster; bounded by Londonderry, on the north; by Armagh and Lough-neah, on the east; by Monaghan and Fermanagh, on the south; and by Donnegal on the west.

U, V.

V A I

VACCINIUM, in botany, a genus of the octandria monogynia class. The calix is above the fruit; the corolla consists of one petal; the filaments are inserted into the receptacle; and the berry has four cells, containing many seeds. There are twelve species, five of them natives of Britain, *viz.* the myrtillus, or black whortleberries or bilberries; the uliginosum, or great bilberry-bush; the cantabricum, or Irish whort; the vitis idea, or red whort; and the oxycoccus, or craw-berries.

VACUUM, in philosophy, denotes a space empty or devoid of all matter or body.

VAGINA, properly signifies a sheath, or scabbard: and the term vagina is used, in architecture, for the part of a terminus, because resembling a sheath, out of which the statue seems to issue.

VAGINA, in anatomy, a large canal, formed of a robust or strong membrane, and reaching from the external orifice, or os pudendi, in women, to the uterus. See **ANATOMY**.

VAGUM, or **PAR VAGUM**. See **ANATOMY**, 249.

VAIR, in heraldry, a kind of fur, consisting of divers little pieces, argent, and azure, resembling a Dutch U, or a bell-glafs. See **PLATE CXLVII.** fig. 21.

VAIRY, in heraldry, expresses a coat, or the bearings of a coat, when charged or chequered with vairs: and hence,

vairy-cuppy, or vairy-tassy, is a bearing composed of pieces representing the tops of crutches. See **PLATE CXLVII.** fig. 22.

VALAIS, a territory of Switzerland, being a long valley of an hundred miles extent, lying between the head of the river Rhône and the lake of Geneva.

VALANTIA, in botany, a genus of the polygamia monoecia class. Neither the hermaphrodite or male have any calix; the corolla of each consists of four segments; there are four stamina; the stylus of the hermaphrodite is bifid, and it has but one seed. There are three species, only one of them, *viz.* the cruciata or cross-wort, a native of Britain.

VALENCIA, the capital of a province of the same name, in Spain, situated in a fine plain on the river Guadalaviar: W. long 35°, N. lat. 39° 20'.

VALENTINIANS, in church-history, a sect of Christian heretics, who sprung up in the 11d century, and were so called from their leader Valentinus.

The Valentinians were only a branch of the Gnostics, who realized or personified the platonic ideas concerning the deity, whom they called Pleroma, or plenitude. Their system was this: the first principle is Bythos, *i. e.* depth, which remained many ages unknown, having with it

-it Eanoë or thought, and Sige or silence; from these sprung the Nous, or intelligence, which is the only son, equal to, and alone capable of comprehending, the Bythos: the filiter of Nous they called Alethia, or truth: and these constituted the first quaternity of æons, which were the source and original of all the rest: for Nous and Alethia produced the world and life; and from these two proceeded man and the church. But besides these eight principal æons, there were twenty two more; the last of which, called Sophia, being desirous to arrive at the knowledge of Bythos, gave herself a great deal of uneasiness, which created in her Anger and Fear, of which was born Matter. But the Horos, or bounder, stopped her, preserved her in the pleroma, and restored her to her perfection. Sophia then produced the Christ and the Holy Spirit, which brought the æons to their last perfection, and made every one of them contribute their utmost to form the Saviour. Here Enthyeme, or thought, dwelling near the Pleroma, perfected by the Christ, produced every thing that is in the world, by its divers passions. The Christ sent into it the Saviour, accompanied with angels, who delivered it from its passions, without annihilating it: from thence was formed corporeal matter. And in this manner did they romance, concerning God, nature, and the mysteries of the Christian religion.

VALERIANA, in botany, a genus of the triandria monogynia class. It has no calix; the corolla consists of one petal, gibbous at the base, and situate above the fruit. There are 20 species, three of them natives of Europe, *viz.* the officinalis, or great wild valerian, whose roots alexipharmic, sudorific, and diuretic; the dioica, or marsh valerian; and the locusta, or lambs-lettuce.

VALET, a French term, used as a common name for all domestic men servants, employed in the more servile offices, as groomes, footmen, coachmen, &c.

VALETUDINARY, among medical writers, denotes a person of a weak and sickly constitution, and frequently out of order.

VALID, in law, an appellation given to acts, deeds, transactions, &c. which are clothed with all the formalities requisite to their being put into execution.

VALLADOLID, a city of Old Castile, in Spain, eighty-six miles north-west of Madrid: W. long. 4° 50', and N. lat. 41° 36'.

VALLENGIN, the capital of a county of the same name, in Switzerland, situated near the lake of Neuchâtel, twenty-five miles north-west of Bern.

VALLISNERIA, in botany, a genus of the diœcia dianthia class. The spathe both of male and female consists of two segments, and the corolla of three petals; the spadix of the male is covered with stamules; the capsule has one cell, containing many seeds; and there are three styli. There is but one species, a native of Italy.

VALOIS, a duchy of France, situated on the three great rivers, the Seine, the Marne, and the Oyse.

VALUE, in commerce, denotes the price or worth of any thing.

VALUED RENT, in Scots law. See **LAW**, Tit. xii. 6.

VALVE, in hydraulics, pneumatics, &c. is a kind of lid, or cover, of a tube or vessel, so contrived as to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture; so that it either admits the entrance of a fluid into the tube or vessel, and

prevents its return; or admits its escape, and prevents its re-entrance.

VALVE, in anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours going one way, and prevent their reflux towards the place from whence they came.

VAN, a term derived from the French *avant*, or *avaunt*, signifying *before*, or *foremost* of any thing: thus we say, the van-guard of an army, &c.

VANDALIA, the ancient name of the countries of Mecklenburg and Pomerania, in Germany.

VANELLUS, in ornithology. See **TRINGA**.

VAPOUR, in philosophy, the moist and most volatile particles of bodies, separated by heat, and raised into the atmosphere. See **RAIN**.

VAPOURS, in medicine, a disease properly called hypo, or the hypochondriacal disease, and in men particularly the spleen. See **MEDICINE**, p. 148.

VARI, in medicine, little hard and ruddy tumours, which frequently infect the faces of young persons of a hot temperament of body.

VARIATION, in geography and navigation, is the deviation of the magnetical needle, in the mariner's compass, from the true north point, towards either the east or west; or it is an arch of the horizon, intercepted between the meridian of the place of observation and the magnetic meridian. See **NAVIGATION**.

VARIEGATION, among botanists and florists, the act of streaking or diversifying the leaves, &c. of plants and flowers with several colours.

Variation is either natural or artificial. Of natural variation there are four kinds; the first shewing itself in yellow spots here and there in the leaves of plants called by gardeners the yellow blotch. The second kind, called the white blotch, marks the leaves with a great number of white spots or stripes; the whitest lying next the surface of the leaves, usually accompanied with other marks of a greenish white, that lie deeper in the body of the leaves. The third, and most beautiful, is where the leaves are edged with white, being owing to some disorder or infection in the juices, which taints the natural complexion or verdure of the plant. The fourth kind is that called the yellow edge.

Artificial variation is performed by inarching or inoculating a striped or variegated plant into a plain one of the same sort; as a variegated common jessamine into a plain, common, Spanish, Brazil, or Indian jessamine.

A single bud or eye, Mr. Bradley observed, being placed in the escutcheon of a diltempered tree, where it can only receive nourishment from the vitiated juices, will become variegated proportionably to the nourishment it draws; and will partake more of the white and yellow juice, than if a branch shall be inarched, the bud having nothing to nourish it but the juices of the plant it is inoculated on; whereas a cyon inarched is fed by the striped plant, and the healthful one.

As to the natural stripes and variegations, there are some particular circumstances to be observed: 1. That some plants only appear variegated or blotched in the spring and autumn, the taints disappearing as they gather strength: of this kind are rue, thyme and marjoram. 2. Some plants are continually blotched in the spongy part of their

their leaves, the sap-vessels all the time remaining of a healthful green; which, being strengthened by rich manure, or being inarched in healthful plants, throw off the distemper. 3. In other plants, the disease is foisted and inveterate, that it is propagated with the feed: such are the arch-angel, water-betony, bark crests, borage, striped cellyary, and fycomore; the sides of which produce striped plants.

VARIOLÆ, the SMALL-POX. See **MEDICINE, p. 75.**

VARIX, in medicine, the dilatation of a vein, arising from the too great abundance or thickness of the blood.

VARNISH, a thick, viscid, shining liquor, used by painters, gilders, and various other artificers, to give a gloss and lustre to the works; as also to defend them from the weather, dust, &c.

There are several kinds of varnishes in use; as the fictative or drying varnish, made of oil of alpin, turpentine, and sandarach melted together. White varnish, called also Venetian varnish, made of oil of turpentine, fine turpentine, and mastic. Spirit of wine varnish, made of sandarach, white amber, gum elmi, and mastic; serving to gild leather, picture-frames, &c. withal.

1. To make the white varnish: take gum fundarach, of the clearest and whitest sort, eight ounces; gum mastic, of the clearest sort, half an ounce; of sarcocolla, the whitest, three quarters of an ounce; Venice turpentine, an ounce and a half; benzoin, the clearest, one quarter of an ounce: white rosin, one quarter of an ounce: gum animæ, three quarters of an ounce: let all these be dissolved, and mixed in the manner following:

Put the sarcocolla and rosin into a little more spirits than will cover them to dissolve; then add the benzoin, gum animæ, and venice-turpentine, into either a glass or glazed earthen vessel, and pour on as much spirits as will cover them an inch; then put the gum mastic into a glass or glazed vessel, and pour strong spirits upon it, covering it also about an inch thick, to dissolve it rightly; then put your gum elemi into a distinct vessel as before, and cover it with spirits to dissolve.

For this purpose, you need only break the rosin a little, and powder the gum animæ, sarcocolla, and benzoin.

Let all stand three or four days to dissolve, shaking the glasses, &c. two or three times a-day, and afterwards put them all together into a glazed vessel, stirring them well, and strain the liquor and gums gently, beginning with the gums, through a linen cloth.

Then put it into a bottle, and let it stand a week before you use it, and pour off as much of the clear only, as you think sufficient for present use.

A hard varnish that will bear the muffle may be thus made: Take of colophony, an ounce; let it over the fire in a well-glazed earthen vessel, till it is melted; then by little and little, strew in two ounces of powder of amber, keeping it stirring all the while with a stick; and when you perceive it begin to harden or resist the stick, then put in a little turpentine oil, which will thin and soften it immediately; then put in two ounces of gum copal, finely powdered, sprinkling it in as you did the amber, now and then pouring in a little oil of turpentine; and when it is done, strain it as before directed.

This is proper to varnish over gold; and the things done with it must be set into a declining oven, three or

four days successively, and then it will resist even the fire itself.

To make a varnish for gold, or metals made in imitation of gold. Take colophony, and, having melted it, put in two ounces of amber finely powdered, and some spirit of turpentine; and, as the amber thickens, keep it well stirring; then put in an ounce of gum elemi, well pulverized, and more spirit of turpentine; constantly stirring the liquor till all is well mixed and incorporated: but take care, however, to use as little turpentine as you can, because the thicker the varnish is made, the harder it will be. Let this be done over a sand-heat, in an open glass: then strain it, as is directed for the preceding varnish. This varnish is to be used alone, first warming the vessels made of paper-paste; and lay it on with a painting-brush before the fire, but not too near, lest the fire raise it into blisters. After this has been done, harden it three several times in ovens; first with a slack heat, the next with a warmer, and the third with a very hot one; and the vessels will look like polished gold.

And as for such vessels, &c. as shall be made with saw dust and gums, the varnish may be made of the same ingredients as above-mentioned, except the gum elemi; and this will dry in the sun, or in a gentle warmth.

To make a varnish for any thing covered with leaf-silver. First paint the thing over with size, and ground chalk or whiting; let them stand till they are thoroughly dry, and then do them over with very good gold-size of a bright colour (for there is much difference in the colour of it, some being yellow, and others almost white; the first is most proper for gold, and the last for silver. When this size is so dry as that it will just stick a little to the touch, lay on the leaf-silver, and close it well to the size.

To make a varnish for silver. Melt, in a well-glazed pipkin, some fine turpentine, and put in three ounces of white amber finely powdered (more or less, according to the quantity your work will require); put it in by little and little, keeping it continually stirring, adding by degrees some spirit of turpentine, till all the amber is dissolved; and then add to it an ounce of sarcocolla well beaten, and an ounce of gum elemi well levigated, adding now and then a little spirit of turpentine, till all is dissolved: do this over a gentle fire, and keep it constantly stirring.

This varnish will be as white and strong as the former; and is to be used warm, and hardened by degrees in an oven, as varnished gold, whereby it will look like polished silver.

Laying on of VARNISHES. 1. If you varnish wood, let your wood be very smooth, close-grained, free from grease, and rubbed with rushes. 2. Lay on your colours as smooth as possible; and, if the varnish has any blisters in it, take them off by a polish with rushes. 3. While you are varnishing, keep your work warm, but not too hot. 4. In laying on your varnish, begin in the middle, and stroke the brush to the outside; then to another extreme part, and so on till all be covered: for if you begin at the edges, the brush will leave blots there, and make the work unequal. 5. In fine works use the finest tripoli in polishing: do not polish it at one time only; but after the first time, let it dry for two or three days, and polish it again for the last time. 6. In the first polishing, you must use a good deal of tripoli; but in the next a very

little will serve: when you have done, wash off your tripoli with a sponge and water: dry the varnish with a dry linen rag; and clear the work, if a white ground, with oil and whitening; or, if black, with oil and lamp-black.

VARNISH also signifies a sort of shining coat, wherewith potter's ware, delf ware, china ware, &c. are covered, which gives them a smoothness and lustre. Melted lead is generally used for the first, and snail for the second.

VARNISH, among medalists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to medals, and art has never yet attained to counterfeit, enhances the value of them; that is, the colour, which certain soils, in which they have a long time lain, tinges the metals withal; some of which are blue, almost as beautiful as the turquoise; others with an inimitable vermilion colour; others with a certain shining polished brown, vastly finer than brass figures.

The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them, more accurately than the finest enamel does on metals.

No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar or lemon-juice.

Falsifiers of medals have a false or modern varnish, which they use on their counterfeits, to give them the appearance, or air, of being antique. But this may be discovered by its softness, it being softer than the natural varnish, which is as hard as the metal itself.

Some deposit their spurious metals in the earth for a considerable time, by which means they contract a sort of varnish, which may impose upon the less knowing; others use sal armoniac, and others burnt paper.

VAS, a vessel either for mechanical, chemical, culinary, or any other uses. In anatomy, all the parts which convey a fluid are called vessels, as the veins, arteries, and lymphatics,

VASCULAR, something consisting of divers vessels; as arteries, veins, nerves, &c.

VASCULIFEROUS PLANTS, such whose seeds are contained in vessels, which are sometimes divided into cells.

VASE, a term frequently used for ancient vessels dug from under ground, or otherwise found, and preserved in the cabinets of the curious.

In architecture, the appellation vase is also given to those ornaments placed on corniches, foches, or pedestals, representing the vessels of the ancients, particularly those used in sacrifice: as incense-pots, flower-pots, &c.

VASSAL, denotes a tenant that holds land in fee of his lord. **VASSAL**, in Scots law. See **LAW**, Tit. x. 3.

VASTUS, in anatomy. See **ANATOMY**, p. 207.

VATERIA, in botany, a genus of the polyandria monogynia class. The corolla consists of five petals, and the calix of five segments; the capsule has three valves, and one cell containing three seeds. There is but one species, a native of India.

VATICAN, a magnificent palace of the pope, in Rome, which is said to consist of several thousand rooms: but the parts of it most admired are the grand stair-case, the pope's apartment; and especially the library, which is one of the richest in the world, both in printed books and manuscripts.

VAUDEMONT, the capital of a county of the same name in Lorrain, fifteen miles south-west of Nancy.

VAUDOIS, are certain valleys situated north of the marquise of Saluzzo, in Italy: the chief town is Lucerne.

VAULT, in architecture, an arched roof, so contrived that the stones which form it sustain each other.

Vaults are, on many occasions, to be preferred to soffits or flat ceilings, as they give a greater height and elevation, and are besides more firm and durable.

VAUR, a town of Languedoc, in France, eighteen miles west of Toulouse.

UBEDA, a city of Andalusia, in Spain, forty-five miles north-east of Granada: W. long. 3° 6', N. lat. 38°.

UBERLINGEN, a town of Swabia, in Germany, ten miles north of Constance.

UBES, or **St. Ubes**, a city and port-town of Portugal, situated on a fine bay, twenty-one miles south of Lisbon.

UBIQUITARIANS, in church-history, a sect of heretics who sprung up in Germany about the year 1590, and maintained that the body of Jesus Christ is *ubique*, everywhere, or in every place, at the same time. However, they were not quite agreed among themselves; some holding, that the body of Jesus Christ, even during his mortal life, was every where; and others dating the ubiquity of his body from the time of his ascension only.

UBIQUITY, omnipresence; an attribute of the Deity, whereby he is always intimately present to all things.

UDDER, that part in brutes wherein the milk is prepared; answering to the mammæ, or breasts, in women.

VECTOR, in astronomy, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipsis, to that centre or focus.

VEDETTE, in the military art, a sentinel on horseback, detached from the main body of the army to discover and give notice of the enemy's designs.

VEER, a sea-term variously used. Thus veering out a rope, denotes the letting it go by hand, or letting it run out of itself. It is not used for letting out any running rope except the sheet.

VEER is also used in reference to the wind; for, when it changes often, they say it veers about.

VEGETABLE, a term applied to all plants, considered as capable of growth; *i. e.* all natural bodies which have parts organically formed for accretion, but not sensation.

VEGETATION, the act whereby plants receive nourishment, and grow. See **AGRICULTURE**, p. 40.

VEGETATIVE SOUL, among philosophers, denotes that principle in plants, by virtue of which they vegetate, or receive nourishment and grow.

VEHICLE, in general, denotes any thing that carries or bears another along; but is more particularly used in pharmacy for any liquid serving to dilute some medicine, in order that it may be administered more commodiously to the patient.

VEIL, a piece of stuff, serving to cover or hide any thing.

In the Romish churches, in time of Lent, they have veils or curtains over the altar, crucifix, images of saints, &c.

A veil or crape is wore on the head by nuns, as a badge of their profession: the novices wear white veils; but those who have made the vows, black ones.

VEIN, in anatomy. See **ANATOMY**, p. 237.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chirt, croil, brownlie,

brownhen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein.

VELA, a remarkable cape on the coast of Terra Firma, in W. long. $73^{\circ} 30'$, and N. lat. 12° .

VELARIUS, in antiquity, an officer in the court of the Roman emperors, being a kind of usher, whose post was behind the curtain in the prince's apartments; as that of the chancellor's was at the entry of the balustrade, and that of the ostiarii at the door. The velarii had a superior of the same denomination who commanded them.

VELAY, the north-east division of Languedoc, in France.

VELITES, in the Roman army, a kind of ancient soldiery, who were armed lightly with a javelin, a cask, cuirasse, and shield.

VELLEITY, in the school-philosophy, is usually defined a languid, cold, and remiss will. Others say, it implies an impotency of obtaining what we require.

VELLA, in botany, a genus of the tetradynamia siliculosa class. The dissepiment of the pod is about twice as large as the valves, and oval on the outside. There are two species, only one of them, *viz.* the annua, or cress-rocket, a native of Britain.

VELOCITY, swiftness, or that affection of motion whereby a moving body is disposed to run over a certain space in a certain time. See **MECHANICS**, and **HYDROSTATICS**.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue.

The principal and best manufactories of velvet are in France and Italy, particularly in Venice, Milan, Florence, Genoa, and Lucca: there are others in Holland, set up by the French refugees, whereof that at Harlem is the most considerable; but they all come short of the beauty of those in France.

VENAL, or **VENOUS**, among anatomists, &c. something that bears a relation to the veins.

This word is also used for something bought with money, or procured by bribes.

VENEERING, a kind of marquetry, or inlaying, whereby several thin slices or leaves of fine woods, of different kinds, are applied and fastened on a ground of some common wood.

VENEREAL, something belonging to venery; as the lues venerea, &c.

VENERY, is used for the act of copulation, or coition, of the two sexes.

VENESECTION, or **PHLEBOTOMY**, in surgery. See **SURGERY**, p. 641.

VENETIAN BOLE, a fine red earth used in painting, and called in the colour-shops Venetian red.

It is dug in Carinthia, and sent from Venice to all parts of the world, being an excellent colour, and very cheap: our colour-men, however, find many ways of adulterating it.

VENEZUELA, a province of Terra Firma, lying on the northern ocean, and having new Andalusia on the east, new Granada on the south, and the river De la Hacha on the west.

VENIAL, in the Romish theology, a term applied to slight sins, and such as easily obtain pardon.

VENICE, the capital of a republic in Italy, of the same name, is situated in the Lagoon, or small islands, of the gulph of Venice, about five miles from the continent: E. long. 12° , and N. lat. $45^{\circ} 40'$.

Venice is so happily situated, that no army can approach it by land; the avenues to those islands being so exceeding difficult, that they have not thought it necessary to inclose the city with a wall.

Nothing can appear more beautiful than this city, as we approach it either from the continent or the sea, with its numerous palaces and lofty towers: its circumference is about six miles, and its inhabitants are computed at two hundred thousand.

VENIRE FACIAS, in law, is a judicial writ lying where two parties plead and come to issue; directed to the sheriff, to cause twelve men, of the same neighbourhood, to meet, and try the fame, and to say the truth upon the issue taken.

VENT, **VENT-HOLE**, or **SPIRACLE**, a little aperture left in the tubes or pipes of fountains, to facilitate the air's escape; or, on occasions, to give them air, as in frosty weather, &c. for want of which they are apt to burst.

VENTER, in anatomy, the same with abdomen. See **ANATOMY**, p. 256.

VENTIDUCTS, in building, are spiracles or subterraneous places, where fresh, cool wind being kept, they are made to communicate, by means of tubes, funnels or vaults, with the chambers or other apartments of a house, to cool them in sultry weather.

VENTILATOR, a well-known machine, by which the noxious air of any close place, as an hospital, goal, ship, chamber, &c. may be changed for fresh air.

VENTRICLE, properly denotes any little cavity; but is more particularly used, by physicians and anatomists, for the stomach.

VENUS, in astronomy. See **ASTRONOMY**, p. 436.

VERA CRUZ, a port-town of Mexico, with a strong and commodious harbour, situated on the gulph of Mexico, in W. long. 100° , N. lat. $18^{\circ} 30'$.

VERAGUA, a province of Mexico, situated on the South Sea, westward of the gulph of Panama.

VERATRUM, in botany, a genus of the polygamia monœcia class. Neither male nor hermaphrodite have any calix; the corolla of each consists of six petals, and they have each six stamina; the hermaphrodite has three pistilli, and three capsules containing many seeds. There are three species, none of them natives of Britain.

VERB, in grammar. See **GRAMMAR**, p. 734.

VERBAL, something that belongs to verbs, or even to words of any kind spoken with the mouth.

VERBAL Agreement, in Scots law. See **LAW**, Tit. xxii. t. &c.

VERBASCUM, in botany, a genus of the pentandria monogynia class. The corolla is rotated, and somewhat unequal; and the capsule has two cells, and two valves. There are twelve species, four of them natives of Britain, *viz.* the thapsus, or great white mullein, the leaves of which are emollient; the lychnitis, or hoary mullein; the nigrum, or black mullein; and the blattoria, or yellow moth-mullein.

VERBENA, in botany, a genus of the diandria monogynia class. The corolla is funnel-shaped, and crooked; one tooth of the calix is truncated; and it has two or

four.

four naked seeds. There are 16 species, **only one** of them, *viz.* the officialis, or vervain, a native of Britain.

VERBERATION, in physics, a term used to express the cause of sound, which arises from a verberation of the air, when struck in divers manners by the several parts of the sonorous body first put into a vibratory motion.

VERBESINA, in botany, a genus of the Syngenesia polygamia superflua class. The receptacle is paleaceous; the pappus is furnished with an awn; the calix is double; and it has about five floccules in the radius. There are 13 species, none of them natives of Britain.

VERD, or **CAPE-VERD**, a promontory of Africa, forty miles north west of the mouth of the river Gambia: W. long. 18° N. lat. 15°.

There are a number of islands in the Atlantic ocean, called Cape-Verd islands, from their being situated off this cape.

VERDIGREASE, a kind of rust of copper, much used by painters as a green colour.

Verdigrease is properly no other than copper dissolved by a mild acid into the form of an ærugo, or rust.

This rust of copper is rarely used internally; nor ought it, unless in the most desperate case, where instantaneous vomiting is necessary. Externally it is much used as a detergent or desiccative: it eats off fungous flesh in ulcers, and, mixed with honey, is used in aphthæ and ulcerations of the mouth.

VERDICT, is the answer of the jury given to the court, concerning the matter of fact, in any case civil or criminal, committed by the court to their trial and examination.

VERDITER, or **VERDETER**, a kind of mineral substance, sometimes used by the painters, &c. for a blue; but more usually mixed with a yellow for a green colour.

VERDOY, in heraldry, denotes a bordure of a coat of arms, charged with any kinds or parts of flowers, fruits, seeds, plants, &c.

VERGETTE, in heraldry, denotes a pallet, or small pale; and hence, a shield divided by such pallets is termed vergette. See **PALE**.

VERIFICATION, in general, is the act of proving a thing; but among the French, it only signifies the recording of the king's edicts by the parliament.

VERJUICE, a liquor obtained from grapes or apples, unfit for wine or cyder; or from sweet ones, whilst yet acid and unripe. Its chief use is in sauces, ragouts, &c. though it is also an ingredient in some medicinal compositions, and is used by the wax-chandlers to purify their wax.

VERMICELLI, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston through a number of little holes.

It was first brought from Italy, where it is in great vogue: it is chiefly used in soups and potrages, to provoke venery, &c.

VERMICULAR, an epithet given to any thing that bears a relation or resemblance to worms.

VERMIFORMIS, in anatomy, a term applied to various parts in the human body, bearing some resemblance to worms.

VERMILION, a very bright and beautiful red colour,

in great esteem among the ancients, under the name of minium. There are two kinds of it, the one natural, the other faditious. The natural is found in some silver mines, in the form of a ruddy sand, which is afterwards prepared and purified by several lotions and coctions. The artificial is made of mineral cinnabar, ground up with aqua-vitæ and urine, and afterwards dried.

It is also made of lead burnt and washed, or of ceruis prepared by fire: but this is not properly called vermilion, but minium, or red-lead.

VERMIN, a collective name including all kinds of little animals, or insects, which are hurtful or troublesome to men, beasts, fruits, &c. as worms, lice, fleas, caterpillars, ants, flies, &c.

VERNACULAR, is applied to any thing that is peculiar to some one country.

VERNAL, something belonging to the spring season.

VERONA, a city of Italy, in the territory of Venice, capital of the Veronese, situated on the Adige: E. long. 11° 15', N. lat. 45° 20'.

VERONICA, in botany, a genus of the diandria monogynia class. The corolla is rotated, and consists of four segments, the lowest one being less than all the rest; and the capsule has two cells. There are 34 species, 13 of them natives of Britain.

VERSAILLES, a town of France, in the province of the isle of France, situated eleven miles west of Paris, where stands one of the most elegant and magnificent palaces in the world, built by Lewis XIV.

VERSE, in poetry, a line or part of a discourse, consisting of a number of long and short syllables, which run with an agreeable cadence, the like being also reiterated in the course of the piece.

VERSE, is also used for a part of a chapter, section, or paragraph, subdivided into several little articles.

VERSIFICATION, the art or manner of making verse; also the tune and cadence of verse.

Verseification is properly applied to what the poet does more by labour, art, and rule, than by invention.

VERSION, a translation of some book or writing, out of one language into another.

VERT, in heraldry, the term for a green colour. It is called vert in the blazon of the coats of all under the degree of nobles; but in coats of nobility, it is called emerald; and in those of kings, venus. In engraving, it is expressed by diagonals, or lines drawn athwart from right to left, from the dexter chief corner to the sinister base, as represented in Plate CXLVII fig. 23.

VERTEBRÆ, in anatomy. See **ANATOMY**, p. 166.

VERTEX, in anatomy, denotes the crown of the head.

Hence vertex is also used figuratively, for the top of other things: thus, the vertex of a cone, pyramid, &c. is the top of any one of these figures.

VERTEX is also used in astronomy, for the point of heaven perpendicularly over our heads, properly called the zenith.

VERTICILLATE PLANTS. See **BOTANY**, p. 637.

VERTICITY, is that property of the loadstone, whereby it turns, or directs itself to some peculiar point.

VEGIGO, in medicine. See **MEDICINE**, p. 146.

V-VRVAIN, in botany. See **VERBENA**.

VERU-MONTANUM, in anatomy. See **ANATOMY**, p. 273.

VESICA,

VESICA, in anatomy. See ANATOMY, p. 269.

VESICATORIUM, an external medicine, serving to raise a blister; whence also it is itself, though improperly, called a blister.

We have vesicatories made of cantharides, euphorbium, figs, sublimate of mercury, lapis infernalis, mustard, anacardium, squills, briony, vinegar, pepper, leaven, &c. VESICULA, a diminutive of vesica, signifying a little bladder.

VESPA, the wasp, in zoology, a genus of insects belonging to the order of hymenoptera. The mouth consists of two jaws without any proboscis; the superior wings are plaited; there is a sharp sting in the tail; and the eyes are lunar. There are 28 species. The common wasps live in societies like the bee. See APIS.

VESPERS, in the church of Rome, denote the afternoon service; answering, in some measure, to the evening-prayers of the church of England.

VESPERTILIO, the bat, in zoology, a genus of quadrupeds belonging to the order of primates. All the teeth are erect, pointed, near each other, and the first four are equal; the fore-feet have the toes connected by a membrane expanded into a kind of wings, by which the creature is enabled to fly. They fly about in the night, and feed upon moths.

VESPERTILIONUM ALÆ, in anatomy. See ANATOMY, p. 275.

VESSEL, denotes in general any thing for holding liquors; such are our domestic cups, pots, &c. as also the retorts, matrasses, crucibles, &c. For the theory and construction of chemical vessels, see CHEMISTRY, p. 108.

In anatomy, all the parts which contain or convey a fluid are called vessels; as the veins, arteries, lymphatics. VESSEL, in navigation, a general name for all sorts of ships. See SHIP.

VESTALIA, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the fifth of the ides of June; that is, on the ninth of that month.

VESTALS, among the ancient Romans, were priestesses of the goddess Vesta, and had the perpetual fire committed to their charge: they were at first only four in number, but afterwards increased to six; and it does not appear that their number ever exceeded six, among whom one was superior to the rest, and called *vestalis maxima*.

The vestals were chosen from six to ten years of age, and obliged to strict continency for thirty years; the first ten of which were employed in learning the ceremonies of religion, the next ten in the performance of them, and the ten last in teaching them to the younger vestals.

The habit of the vestals consisted of an head-dress, called infula, which sat close to their heads, and from whence hung certain laces called vittæ; a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBLE, in architecture, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the stair-case.

VESTIBLE of the ear, in anatomy. See ANATOMY, p. 297.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting at such place, consisting of the minister, church-wardens, and chief men of most parishes, who make a parish vestry or meeting.

By custom there are select vestries, being a certain number of persons chosen to have the government of the parish, make rates, and take the accounts of church-wardens, &c. VESUVIUS, a famous volcano, or burning mountain, situated only six miles east of the city of Naples, in Italy. See VOLCANO.

VETCH, in botany. See VICIA.

VETERAN, among the ancient Romans, an appellation given to a soldier who was grown old in the service, or had made a certain number of campaigns.

VIALES, in mythology, a name given among the Romans to the gods who had the care and guard of the roads and high-ways.

VIATICUM, in the church of Rome, an appellation given to the eucharist when administered to persons at the point of death.

VIATOR, in Roman antiquity, an appellation given in common to all officers of any of the magistrates; as lictors, acenti, scribes, criers, &c.

VIBEX, is sometimes used, by physicians, for a black and blue spot in the skin, occasioned by an afflux or extravasation of blood.

VIBRATION, in mechanics, a regular, reciprocal motion of a body, as a pendulum, &c.

VIBURNUM, in botany, a genus of the pentandria tri-gynia class. The calix is above the fruit, and consists of five segments; the corolla has likewise five segments, and the berry contains one seed. There are nine species, two of them natives of Britain, viz. the lantana, or way-faring tree; and the opulus, or water-elder.

VICAR, a person appointed, as deputy to another, to perform his functions in his absence, and under his authority.

VICAR, in the canon law, denotes a priest of a parish, the predial tithes whereof are impropriated or appropriated; that is, belong either to a chapter, religious house, &c. or to a layman, who receives them, and only allows the vicar the small tithes, or a convenient salary.

VICE, in ethics, is ordinarily defined an elective habit, deviating, either in excess, or defect, from the just medium wherein virtue is placed.

Vice, in smithery, and other arts employed in metals, is a machine, or instrument, serving to hold fast any thing they are at work upon, whether it is to be filed, bent, rivetted, &c.

Vice is also used, in the composition of divers words, to denote the relation of something that comes instead, or in the place, of another; as vice-admiral, vice-chancellor, vice chamberlain, vice-president, &c. are officers who take place in the absence of admirals, &c.

VICE-ROY, a governor of a kingdom, who commands in the name and stead of a king, with full and sovereign authority. See KING.

VICIA, in botany, a genus of the diadelphia decandria class. The under side of the stigma is transversely bearded. There are 18 species, six of them natives of Britain, viz. the eracca, or tufted wood-vetch; the scorpion, or bush-vetch; the sativa, or common vetch; the lathyroides, or wild-vetch; and the lutea, or yellow vetch.

VICISSITUDE, the regular succession of one thing after another; as the vicissitude of day and night, of the seasons, &c.

VISCOUNT, a degree of nobility next below a count, or earl, and above a baron.

VICTIM, denotes a bloody sacrifice, offered to some deity, of

- of a living creature, as a man or beast, which is flin to appease his wrath, or obtain some favour.
- VICTIMARIUS**, in antiquity, a minister or servant of the priest, whose office was to bind the victims, and prepare the water, knife, and other things necessary for the sacrifice.
- VICTORY**, the overthrow or defeat of an enemy, in war or combat.
- VICTUALLING-OFFICE**, an office kept on Tower-hill, London, for the furnishing his majesty's navy with victuals.
- VICTUALS**, signifies any sustenance, or things necessary to live upon, as meat and provisions.
- VIENNA**, the capital city of the circle of Austria and of the German empire, is situated on the Danube, in E. long. 16° 21', and N. lat. 48° 20'.
- Vienna is an archbishop's see, and has a celebrated university.
- VIGILS**, in church-history, are the fasts appointed before certain festivals, in order to prepare the mind for a due observation of the ensuing solemnity.
- VIGO**, a port-town of Galicia, in Spain, 70 miles south-east of Cape Finisterre: W. long. 9° 18', N. lat. 42° 15'.
- VILLA-FRANCA**, the name of several towns, one in Piedmont, three miles east of Nice; another of Catalonia, eighteen miles west of Barcelona; a third, the capital of St Michael, one of the Azores; and a fourth, a town of Estramadura, in Spain, fifty-four miles south-east of Salamanca.
- VILLA-FRANCHE**, a town of Orleanois, in France, twelve miles north of Lyons.
- VILLAGE**, an assemblage of houses, inhabited chiefly by peasants and farmers, and having no market, whereby it is distinguished from a town.
- VILLAIN**, or **VILLEIN**, in our ancient customs, denotes a man of servile and base condition, *viz.* a bondman or servant.
- VILLA-REAL**, the name of two towns; the one in Spain, thirty miles north of Valencia; and the other in Portugal, fifty miles east of Porto.
- VILLA-RICA**, a port town of Mexico, situated on the gulph of Mexico, in W. long. 100°, and N. lat. 20°.
- VILLENAGE**, a kind of ancient tenure, whereby the tenant was bound to do such services as the lord commanded, or such as were fit for villains or bondmen to perform.
- VILLI**, among botanists, a kind of down, like coarse hair, with which some trees abound.
- VILLOSE**, or **VILLOUS**, something abounding with villi, or fibres like coarse hairs: such is one of the coats of the stomach.
- VINALIA**, in Roman antiquity, a festival on the ninth of the kalends of May, in honour both of Jupiter and Venus.
- VINCA**, in botany, a genus of the pentandria monogynia class. It has two erect follicles; the seeds are plumose; and the tube of the corolla terminates in a lacerated corona. There are four species, two of them natives of Britain, *viz.* the minor, or periwinkle; and major, or greater periwinkle.
- Cape* **VINCEN**, the most south-west promontory of Portugal: W. long. 10°, and N. lat. 36° 55'.
- St* **VINCENT**, one of the Caribbee islands, seventy-five miles west of Barbadoes.

St **VINCENT**, is also a province of Brazil, bounded by the Rio Janiero on the north, by the Atlantic on the east, by the province of del Rey on the south, and by that of the Spanish La Plata on the west.

VINDEMIATING, the gathering of the grapes, or other ripe fruits, as apples, pears, cherries, &c.

VINDEMIATRIX, or **VINDEMIATOR**, a fixed star of the third magnitude in the constellation virgo.

VINE. See **VITIS**.

VINEGAR, an acid penetrating liquor, prepared from wine, cyder, beer, &c. of considerable use both as a medicine and sauce. See **CHEMISTRY**, p. 97, 166.

VINEYARD, a plantation of vines.

The best situation of a vineyard is on the declivity of an hill, lying on the south.

VINOUS, something that relates to wine, or that has the taste and smell thereof. See **WINE**.

VINTAGE, a crop of wine, or what is got from the vines each season.

VINUM, a liquor or drink commonly called wine. See **WINE**.

VIOL, a musical instrument of the same form with the violin, and struck like that with a bow.

VIOLA, in botany, a genus of the syngenesia monogynia class. The calix consists of five leaves, and the corolla of five irregular petals horned behind; the capsule has three valves, and one cell. There are 24 species, seven of them natives of Britain.

VIOLATION, the act of violating, that is, forcing a woman, or committing a rape upon her.

This term is also used, in a moral sense, for a breach or infringement of a law, ordinance, or the like.

VIOLENT, in the schools, a thing done by force; in which sense it stands opposed to spontaneous.

VIOLENT Profit, in Scots law. See **LAW**, Tit. xiii. 20.

VIOLET, in botany. See **VIOLA**.

VIOLIN, or **FIDDLE**, a musical instrument mounted with four strings, or guts, and struck, or played, with a bow.

VIOLONCELLO, of the Italians is properly our fifth violin; which is a little bass-violin, half the size of the common bass-violin, and its strings just half as thick and half as long, which renders the sound just an octave higher than the same.

VIOLONE, in music, a double bass, almost twice as big as the common bass-violin, and the strings bigger and longer in proportion, and consequently its sound an octave lower than that of our bass-violin, which has a noble effect in great concerts.

VIPER, in zoology. See **COLUBER**.

VIRAGO, a woman of extraordinary stature and courage; and who, with the female sex, has the mien and air of a man, and performs the actions and exercises of men.

VIRGA AUREA, in botany. See **SOLIDAGO**.

VIRGA SANGUINEA, in botany. See **CORNUS**.

VIRGIN, a female who has had no carnal commerce with man.

VIRGIN is also applied figuratively to several things that retain their absolute purity, and have never been made use of.

VIRGIN ISLANDS, very small islands of the Caribbees, situated in the Atlantic or American-ocean, a little to the eastward of Porto-Rico.

VIRGINIA, one of the British American colonies, situated between seventy-four and eighty degrees west long. and between thirty-six and thirty-nine degrees of north lat.

- fat. bounded by the river Patowmack, which separates it from Maryland, on the north; by the Atlantic-ocean, on the east; by Carolina, on the south; and may be extended as far westward as we think fit.
- VIRGINITY**, the test or criterion of a virgin, or that which intitles her to the denomination.
- VIRGO**, in astronomy, one of the signs or constellations of the zodiac. See **ASTRONOMY**, p. 487.
- VIRILE**, something that belongs or is peculiar to a man, or the male sex.
- VIRTUAL**, or **POTENTIAL**, something that has a power or virtue of acting or doing. The term is chiefly understood of something that acts by a secret invincible cause, in opposition to actual and sensible.
- VIRTUE**, a term used in various significations. In the general it denotes power, or perfection of any thing, whether natural or supernatural, animate or inanimate, essential or accessory. But in its more proper or restrained sense, virtue signifies an habit, which improves and perfects the possessor and his actions.
- VIRTUOSO**, an Italian term, lately introduced into English, signifying a man of curiosity and learning, or one who loves and promotes the arts and sciences: but among us the term seems to be appropriated to those who apply themselves to some curious and quaint, rather than immediately useful, art or study, as antiquaries, collectors of rarities of any kind, microscopical observers, &c.
- VIRULENT**, a term applied to any thing that yields a virus, that is, a contagious or malignant pus.
- VISCERA**, in anatomy, a term signifying the fame with entrails, including the heart, liver, lungs, spleen, intestines, and other inward parts of the body. See **ANATOMY**, Part VI.
- VISCIDITY**, or **VISCOSITY**, the quality of something that is viscid or viscous, that is, glutinous and sticky, like bird-lime, which the Latins call by the name *viscus*.
- VISCUM**, in botany, a genus of the dicæta tetrandria class. The calix of both male and female consists of four segments; neither of them have any corolla; there are no filaments in the male, the antheræ being connected to the calix; the female has no stylus; and the berry contains one heart-shaped seed. There are six species, none of them natives of Britain.
- VISIBLE**, something that is an object of sight or vision, or something whereby the eye is affected, so as to produce a sensation.
- VISIER**, an officer or dignitary in the Ottoman empire, whereof there are two kinds; the first, called by the Turks visier-azem, that is, grand visier, is the prime minister of state of the whole empire. He commands the army in chief, and presides in the divan or great council. Next to him are six other subordinate visiers, called visiers of the bench, who officiate as his counsellors, or assessors in the divan.
- VISION**, in optics, the act of seeing or perceiving external objects, by means of the organ of sight, the eye. See **ANATOMY**, p. 289. and **OPTICS**.
- VISTULA**, or **WEISSEL**, a large river of Poland, which, taking its rise in the mountains south of Silesia, visits Cracow, Warsaw, &c. and continuing its course north, falls into the Baltic sea below Dantzick.
- VISUAL**, in general, something belonging to vision.
- VITAL**, in physiology, an appellation given to whatever ministers principally to the constituting or maintaining of life in the bodies of animals: thus, the heart, lungs, and brain are called vital parts; and those operations of these parts, whereby the life of animals is maintained, are called vital functions.
- VITEX**, in botany, a genus of the didynamia angiospermia class. The corolla consists of six segments, and the calix of five teeth; and the berry contains four seeds. There are four species, none of them natives of Britain.
- VITIS**, the vine, in botany, a genus of the pentandria monogynia class. The petals adhere at the apex; and the berry contains five seeds. There are seven species, none of them natives of Britain.
- VITIS IDÆA**, in botany. See **VACCINIUM**.
- VITIOUS INTROMISSION**, in Scots law. See **LAW**, Tit. xxviii. 20.
- VITREOUS Humour of the Eye**. See **ANATOMY**, p. 289.
- VITRIFICATION**, in chemistry, is the converting a body into glass, by means of fire.
- VITRIOL**, a compound body formed of the particles of metals dissolved by the acid of sulphur, and that either by the operations of nature within the earth, or in the chemists laboratory by proper admixtures and assistances, and afterwards, by the help of water, brought into the form of a salt. See **CHEMISTRY**, p. 81, 132.
- VITRIOLATED**, among chemists, something that has vitriol infused in it.
- VITRIOLIC**, an appellation given to whatever abounds with, or partakes of, the nature of vitriol: thus such fossil bodies as contain vitriol, are called vitriolic minerals, or ores of vitriol.
- VITA**, in anatomy, that part of the amnios which sticks to an infant's head when just born.
- VITUS'S DANCE**. See **MEDICINE**, p. 99.
- VIVERRA**, in zoology, a genus of quadrupeds belonging to the order of feræ. They have six fore-teeth, the intermediate ones being shorter, and more than three grinders; and the claws are exerted. There are six species, viz. 1. The ichneumon, with the tail tapering towards the point, and the toes distant from each other. It is a native of Egypt and India, where it is tamed, and follows its master like a dog. It feeds upon lizards, frogs, &c. and is particularly an enemy to serpents. 2. The *nasua*, is reddish, with white rings on the tail. It is a native of America, and digs the ground in search of worms; it feeds likewise upon mice, and fruits; when enraged, it sends forth an abominable stench. 3. The *narica* is of a dusky colour; it is likewise a native of America. 4. The *putorius* varies in colour, but has generally four white parallel lines on the back. It is a native of North America, is slow in its motion, and emits its urine, attended with a most disagreeable smell, when enraged. 5. The *zibetha*, has an annulated tail, and the back is streaked with waves of black and ash-colour. It is a native of China, and Mexico. It is a fierce and ungovernable animal, and erects the hairs of its back when angry. 6. The *genetta* has an annulated tail, and the body is spotted with a dirty yellow and black colour. It is a native of the East, and smells of musk.
- VIVIPAROUS**, in natural history, an epithet applied to such animals as bring forth their young alive and perfect; in contradistinction to them that lay eggs, which are called oviparous animals.

UKRAIN, a province of Muscovy, lying northwards of Little Tartary, so called as being a frontier against Turkey.

ULADISLAW, a city of Great Poland, situated on the river Borzithenes, eighty-miles north-west of Warlaw: E. long. 19°, and N. lat. 53°.

ULCER, in surgery. See SURGERY, p. 646.

ULCERATION, in surgery, a little hole in the skin, caused by an ulcer.

ULEX, in botany, a genus of the diadelphia decandria class. The calix consists of two leaves; and the pod is about the length of the calix. There are two species, one of them, *viz.* the europæus, or furze, a native of Britain.

ULIGINOUS, in agriculture, an appellation given to a moist, moorish, and fenfy soil.

ULLAGE, in gauging, is so much of a cask or other vessel, as it wants of being full.

ULM, an imperial city of Swabia, in Germany, ninety miles south-west of Ratibon: E. long. 10°, N. lat. 48° 24'.

ULMARIA, in botany. See FILIPENDULA.

ULMUS, in botany, a genus of the pentandria digynia class. The calix consists of five segments; it has no corolla; and the berry is dry, compressed, and membranaceous. There are three species, two of them natives of Britain, *viz.* the campestris, or common elm; and the glabra, or broad-leaved elm.

ULNA, in anatomy. See ANATOMY, p. 178.

ULNARIS, in anatomy. See ANATOMY, p. 199.

ULSTER, the most northern province of Ireland, the chief town of which is Londonderry.

ULTERIOR, in geography, is applied to some part of a country or province, which, with regard to the rest of that country, is situated on the farther side of the river, mountain, or other boundary, which divides the country into two parts.

ULTIMUS HÆRES, in Scots law. See LAW, Tit. xxix. 1, 2.

ULTRAMARINE, a beautiful blue colour used by the painters, prepared from lapis lazuli by calcination.

ULTRAMONTANE, something beyond the mountains.

The term is principally used in relation to Italy and France, which are separated by the mountains of the Alps.

ULVA, in botany, a genus of the cryptogamia algae class, consisting of a merely foliaceous substance, formed into long cylindrical tubes. There are 10 species, all natives of Britain.

ULULA, in ornithology. See STRIX.

UMBELLÆ. See BOTANY, p. 637.

UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like an umbrella.

UMBILICAL, among anatomists, something relating to the umbilicus or navel.

UMBILICUS the NAVEL, in anatomy. See ANATOMY, p. 257, and MIDWIFERY.

UMBONE, a name used by some for the style or pistil of a flower.

UMPIRE, a third person chosen to decide a controversy left to arbitration.

UNCIA, in general, a Latin term denoting the twelfth part of any thing; particularly the twelfth part of a pound,

called in English an ounce; or the twelfth part of a foot, called an inch.

UNCTION, the act of anointing or rubbing with oil or other fatty matter.

UNCTION, in matters of religion, is used for the character conferred on sacred things, by anointing them with oil. Unctions were very frequent among the Hebrews. They anointed both their kings and high-priests at the ceremony of their inauguration. They also anointed the sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The unction of kings is supposed to be a ceremony introduced very late among the Christian princes. It is said, that none of the emperors were ever anointed before Justinian, or Justin. The emperors of Germany took the practice from those of the eastern empire: king Pepin of France was the first who received the unction. In the ancient Christian church, unction always accompanied the ceremonies of baptism and confirmation. Extreme unction, or the anointing persons in the article of death, was also practised by the ancient Christians, in compliance with the precept of St James, chap. v. 14. and 15 verses; and this extreme unction the Romish church has advanced to the dignity of a sacrament. It is administered to none but such as are afflicted with some mortal disease, or are in a decrepit age. It is refused to impenitent persons, as also to criminals. The parts to be anointed are the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins. The laity are anointed in the palms of the hands, but priests on the back of it; because the palms of their hands have been already consecrated by ordination. The parts above-mentioned are anointed in the form of a cross. The priest begins anointing the sick person's eyes, saying, "May God, by his holy anointing, pardon you the sins you have committed by the eyes." In like manner he proceeds to the other parts, varying the words according to the parts he anoints.

UNDECAGON, is a regular polygon, of eleven sides.

UNDECEMVR, a magistrate among the ancient Athenians, who had ten other colleagues or associates joined with him in the same commission. The function of the undecemviri at Athens were much the same as those of the prévôts de maréchaussée in France: they took care of the apprehending of criminals, secured them in the hands of justice, and when they were condemned, took them again into custody, that the sentence might be executed on them. They were chosen by the tribes, each tribe naming its own; and as the number of the tribes after Callisthenes was but ten, which made ten members, a scribe or notary was added, which made the number eleven.

UNDER the sea, in the sea-language. A ship is said to be so when she lies still, or waits for some other ships, with her helm lashed, or tied up a-lee.

UNDERSTANDING. See METAPHYSICS, and LOGIC.

UNDERWALD, a canton of Switzerland, bounded by Switz and Lucern on the north, by Uri on the east, and by another part of Lucern on the west; being about 25 miles long, and as many broad.

UNDERWOOD, is coppice, or any wood that is not accounted timber.

UNDULA-

UNDULATION, in physics, a kind of tremulous motion or vibration observable in a liquid, whereby it alternately rises and falls like the waves of the sea.

This undulatory motion, if the liquid be smooth and at rest, is propagated in concentric circles, as most people have observed upon throwing a stone or other matter upon the surface of a stagnant water, or even upon touching the surface of the water lightly with the finger or the like. The reason of these circular undulations is, that by touching the surface with your finger, there is produced a depression of the water in the place of contact. By this depression the subjacent parts are moved successively out of their place, and the other adjacent parts thrust upwards, which lying successively on the descending liquid, follow it; and thus the parts of the liquid are alternately raised and depressed, and that circularly. When a stone is thrown into the liquid, the reciprocal vibrations are more conspicuous.

Undulatory motion is likewise applied to a motion in the air, whereby its parts are agitated after the like manner as waves in the sea; as is supposed to be the case when the string of a musical instrument is struck. This undulatory motion of the air, is supposed the matter or cause of sound.

UNGUENT, in medicine and surgery, a topical remedy or composition, chiefly used in the dressing of wounds and ulcers.

UNGUIS, in anatomy. See **ANATOMY**, p. 160.

UNGUIS, among botanists. See **BOTANY**, p. 637.

UNGULA, in geometry, the section of a cylinder cut off by a plane passing obliquely through the plane of the base and part of the cylindric surface.

UNGULA, in natural history, the claw or hoof of a quadruped.

UNICORN, an animal famous among the ancients, but looked on by the moderns as fabulous.

UNICORN-FISH, in ichthyology. See **MONODON**.

UNIFORM denotes a thing to be similar, or consistent, either with another thing or with itself, in respect of figure, structure, proportion, and the like; in which sense it stands opposed to dissimilar.

UNIFORMITY, a similitude, or resemblance, between the parts of a whole: such is that we meet with in figures of many sides, and angles respectively equal, and answerable to each other.

UNIOLA, in botany, a genus of the triandria digynia class. The calix consists of many valves; and the spica is oval and carinated. There are four species, none of them natives of Britain.

UNION, a junction, coalition, or assemblage of two or more different things in one.

UNION OF LANDS, in Scots law. See **LAW**, Tit. x. 20.

UNION, or the **UNION**, by way of eminence, is more particularly used to express the act whereby the two separate kingdoms of England and Scotland were incorporated into one, under the title of The kingdom of Great-Britain. This happy union, in vain attempted by king James I. was at length effected in the year 1707, by the general consent of the queen and the estates of each realm. The chief articles of this union are, That the two kingdoms shall be united into one kingdom, by the name of Great-Britain: that they, in consequence thereof, be represented by one parliament, of which sixteen peers and forty-

five commoners are to be elected for Scotland, and have the same privileges with those of England: that the subjects of either nation shall have equal freedom of trade, and be liable to the same custom, and the like laws for public government, &c. The kirk or church of Scotland is confirmed; and the courts of justice are to remain the same as they were before the union, yet subject to regulation, &c. A court of exchequer is also erected in Scotland, to be a court of record, revenue, and judicature, for ever; and barons of the said court are appointed, who shall be the judges there.

UNISON, in music, the effect of two sounds which are equal in degree of tune, or in point of gravity and acuteness.

UNIT, or **UNITY**, in arithmetick, the number one, or one single individual part of discrete quantity.

UNITED NETHERLANDS consist of the provinces of Holland, Zealand, Friesland, Groningen, Overijssel, Gelderland, with Zutphen and Utrecht; these are bounded by the German sea on the north and west; by the circle of Westphalia, on the east; and by Flanders, Brabant, and the duchy of Cleves, on the south: lying between 3° 20' and 7° 30' east longitude, and between 51° 35' and 52° 40' north latitude; being about fifty miles long, and as many broad, including the Zuyder-sea, which takes up a considerable space between these limits.

UNITY, in poetry. In the drama there are three unities to be observed, viz. the unity of action, that of time, and that of place. In the epic poem, the great, and almost only unity, is that of the action. Some regard indeed ought to be had to that of time; that of place there is no room for. The unity of character is not reckoned among the unities. See **COMPOSITION**.

UNIVERSAL, something that is common to many things, or it is one thing belonging to many or all things.

UNIVERSE, a collective name, signifying the whole world, or the assemblage of heaven and earth, with all things therein. See **ASTRONOMY**, and **GEOGRAPHY**.

UNIVERSITY, a collective term, applied to an assemblage of several colleges, established in a city, wherein are professors in the several sciences, appointed to teach them to students, and where degrees or certificates of study in the divers faculties are taken up.

In each university four faculties are usually taught, theology, medicine, law, and the arts and sciences.

They are called universities, or universal schools, by reason the four faculties are supposed to take in the whole compass of study.

Universities had their first rise in the XIIth and XIIIth centuries. Those of Paris and Bologna pretend to be the first that were set on foot; but they were on a different footing from the universities among us.

The universities of Oxford and Cambridge seem entitled to greatest antiquity of any in the world; and Baliol and Merton colleges in Oxford, and St. Peter's in Cambridge, all made colleges in the XIIIth century, may be said to be the first regular endowments of this kind in Europe.

The universities of Scotland are four, viz. those of St. Andrews, Aberdeen, Edinburgh, and Glasgow. See **EDINBURGH**, &c.

UNIVOCAL, in the schools, is applied to two or more names, or terms that have but one signification; in opposition to equivocal,

equivocal, which is where one term has two or more significations.

UNLAWFUL, illegal, something prohibited by, or contrary to the terms of law, either divine or human.

UNMOOR, a term used at sea. When a vessel which was riding at anchor, weighs the same, or gets it up, in order to sail, they say she is unmooring.

VOCABULARY, in grammar, denotes the collection of the words of a language, with their significations, otherwise called a dictionary, lexicon, or nomenclature. See **DICTIONARY**.

A vocabulary is properly a lesser kind of dictionary, which does not enter so minutely into the origins and different acceptations of words.

VOCAL, something that relates to the voice or speech: thus vocal musick is that set to words, especially verses, and to be performed by the voice; in contradistinction to instrumental musick, composed only for instruments, without singing.

VOCATIVE, in grammar, the fifth state or case of nouns.

When we name the person we are speaking to, or address ourselves to the thing we are speaking of, as if it were a person, the noun or name requires a new relation, which the Latins and Greeks express by a new termination, called the vocative; as, from *dominus*, a lord, is formed the vocative *domine*, O lord.

VOICE, a sound produced in the throat and mouth of an animal, by an apparatus of instruments for that purpose.

Voices are either articulate or inarticulate. Articulate voices are those whereof several conspire together to form some assemblage or little system of sounds; such are the voices expressing the letters of an alphabet, numbers of which joined together form words. Inarticulate voices are such as are not organized, or assembled into words; such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

The formation of the human voice, with all the varieties thereof observed in speech, musick, &c. makes a very curious article of inquiry; and the apparatus and organization of the parts administering thereto, is something exceedingly surprising. Those parts are the trachea or wind-pipe, through which the air passes and repasses into the lungs; the larynx, which is a short cylindric canal at the head of the trachea; and the glottis, which is a little oval cleft or chink left between two semicircular membranes stretched horizontally within the larynx; which membranes, though capable of joining close together, do generally leave an interval either greater or less between them called the glottis. A particular description of each part may be seen in Anatomy, Part IV.

VOICE, in grammar, a circumstance in verbs, whereby they come to be considered as either active or passive; i. e. either expressing an action impressed on another subject, as, *I beat*; or receiving it from another, as *I am beaten*. See **GRAMMAR**, p. 738.

VOICE, in matters of election, denotes a vote or suffrage.

VOIDED, in heraldry, is understood of an ordinary whose inner or middle part is cut out, leaving nothing but its edges to shew its form, so that the field appears through it. Hence it is needless to express the colour or metal of the voided part, because it must of course be that of the field.

VOIDER, in heraldry, one of the ordinaries whose figure is much like that of a staff or saunch, only that it doth not bend so much. See Plate CXLVII, fig. 24.

VOL, among heralds, signifies the two wings of a fowl joined together, borne in armory, as being the whole that makes the flight. Accordingly, a demi-vol is a single wing.

VOLA, the palm or inside of the hand, comprehended between the fingers and the wrist.

VOLANT, in heraldry, is when a bird in a coat of arms is drawn flying, or having its wings spread out.

VOLATILE, in physics, is commonly used to denote a mixed body whose integral parts are easily dissipated by fire or heat; but is more properly used for bodies whose elements or first component parts are easily separated from each other, and dispersed in air. See **CHEMISTRY**.

VOLATILISATION, the act of rendering fixed bodies volatile, or of resolving them by fire into a fine subtle vapour or spirit, which easily dissipates and flies away. All bodies, even the most fixed, as gold, may be volatilized; either of themselves, or with the admixture of some volatile substance, or spirit, by distillation or sublimation.

VOLERY, a great bird-cage, so large that the birds have room to fly up and down in it.

VOLHINIA, or **VOLONIA**, a province of Poland, bounded by Polesia, on the north; by the lower Volhnia, or Ukrain, in the territories of Russia on the east; by Podolia, on the south; and by the province of Red Russia, on the west.

VOLITION, the act of willing. See **METAPHYSICS**.

VOLKAMERIA, in botany, a genus of the didynamia-angiospermia class. The calix consists of five segments; and the berry contains two biculcar seeds. There are two species, none of them native of Britain.

VOLLEY, a military salute, made by discharging a great number of fire arms at the same time.

VOLO, in Roman antiquity, an appellation given to the slaves, who, during the second Punic war, offered themselves to serve in the army.

VOLT, in the manege, a round or circular tread: and hence by the phrase, to make volts, is understood a gate of two treads, made by a horse going sideways round a center, in such a manner, that these two treads make parallel tracks, one larger made by the fore feet, and another smaller made by the hind-feet, the croup approaching to wards the centre, and the shoulders bearing outwards.

VOLUME, in matters of literature, a book, or writing, of a just bulk to be bound by itself. The name is derived from the Latin *volvere*, to roll up; the ancient manner of making up books being in rolls of bark or parchment. See **BOOK**.

VOLUNTARY, in musick, a piece played by a musician extempore, according to his fancy. This is often used before he begins to set himself to play any particular composition, to try the instrument, and to lead him into the key of the piece he intends to perform.

VOLUNTEERS, in the military art, persons who of their own accord, and at their own expence, serve in the army.

VOLUTA in natural history, a genus of insects belonging to the order of vermes testacea. It is an animal of the snail kind, with an unilocular spiral shell, of which there are 46 species, distinguished by peculiarities in their shells.

VOLUTE, in architecture, a kind of spiral scroll, used in the

the Ionic and Composite capitals, whereof it makes the principal characteristic and ornament. See ARCHITECTURE, p. 352.

VOLVULUS, in medicine, a name which some authors give to the iliac passion. See MEDICINE, p. 114.

VOMIR, in anatomy. See ANATOMY, p. 163.

VOMICA, in medicine, is commonly taken for a suppurated impothume, or an abscess with a suppuration. See MEDICINE, p. 104.

Vul. Vomica, in pharmacy, a flat compressed round fruit, of the breadth of a shilling, or somewhat more, and of about the thickness of a crown-piece.

It is the nucleus of a fruit of an East-Indian tree, the wood of which is the lignum colubinum of the shops.

Some have prescribed small doses of the pux vomica as a specific against a gonorrhœa, and others against quartan agues. But we have so many good and safe medicines for all these purposes, that there seems no occasion for our having recourse to such as these, which shew too many signs of mischief.

VOMIR, in pharmacy. See EMETIC.

VOMITING, in medicine, a retrograde spasmodic motion of the muscular fibres of the œsophagus, stomach, and intestines, attended with strong convulsions of the muscles of the abdomen and diaphragm, which, when gentle, create a nausea; when violent, a vomiting. See MEDICINE, p. 115.

VOORN, one of the islands of Holland, bounded by the river Maes, which divides it from the continent and the island of IJsemunde, on the north; by the sea called the Biesbosch, on the east; by another branch of the Maes, which divides it from the islands of Goree and Overflakke, on the south; and by the German sea, on the west; being about twenty-four miles long, and five broad.

VORTEX in meteorology, a whirlwind, or sudden, rapid, and violent motion of the air in gyres, or circles.

Vortex is also used for an eddy or whirlpool; or a body of water, in certain seas or rivers, which runs rapidly around, forming a sort of cavity in the middle.

VORTEX, in the Cartesian philosophy, is a system or collection of particles of matter moving the same way, and around the same axis.

Such vortices are the grand machines, whereby those philosophers solve most of the motions and other phenomena of the heavenly bodies. Accordingly, the doctrine of these vortices marks a great part of the Cartesian philosophy.

VOTE, the suffrage or resolve of each of the members of an assembly, where any affair is to be carried by a majority; but more particularly used for the resolves of the members of either house of parliament.

VOTIVE MEDALS, those on which are expressed the vows of the people for the emperors or empresses. See MEDAL.

VOW, a solemn and religious promise, or oath. See OATH.

The use of vows is found in most religions. They make up a considerable part of the pagan worship, being made either in consequence of some deliverance, under some pressing necessity, or for the success of some enterprise. Among the Jews all vows were to be voluntary, and made by persons wholly in their own power; and if such person made a vow, in any thing lawful and possible, he was obliged to fulfil it. If he appointed no particular

time for accomplishing his vow, he was bound to do it instantly, lest by delay he should prove less able, or be unwilling, to execute his promise. Among the Romanists, a person is constituted a religious by taking three vows, that of poverty, chastity, and obedience.

VOWS, among the Romans, signified sacrifices, offerings, presents, and prayers made for the Cæsars and emperors, particularly for their prosperity and the continuance of their empire. These were at first made every five years, then every fifteen, and afterwards every twenty, and were called quinquennalia, decennalia, and vincennalia.

VOWEL, in grammar, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard, and to form a distinct voice.

The vowels are six in number, viz. A, E, I, O, U, Y, and are called vowels, in contradistinction to certain other letters, which, depending on a particular application of some part of the mouth, as the teeth, lips or palate, can make no perfect sound without an opening of the mouth, that is, without the addition of a vowel, and are therefore called consonants.

UPHOLSTER, **UPHOLSTERER**, or **UPHOLDER**, a tradesman that makes beds, and all sorts of furniture thereunto belonging, &c.

UPLAND, denotes high ground, or, as some call it, terra firma, by which it stands opposed to such as is moorish, marshy, or low.

UPLAND, a province of Sweden, bounded by the province of Gestricia on the north-west, by the Baltic sea on the north-east and south-east, and by Sunderland and Weismania on the south and west.

UPPINGHAM, a market-town of England, in the county of Rutland, situated six miles south of Okeham.

UPRIGHT, in heraldry, is used in respect of shell-fishes, as crevices, &c. when standing erect in a coat. Inasmuch as they want fins, they cannot, according to Guillim, be properly said to be hauriant, that being a term appropriated to scaly fishes.

UPSAL, a city once the capital of the province of Upland, and of all Sweden, being the only archbishop's see in Scandinavia, and an university; situated in E. long. 17° 30', N. lat. 60°.

UPTON, a market-town of Worcestershire, nine miles south of Worcester.

UPUPA, in ornithology, a genus belonging to the order of picæ. The beak is arcuated, convex, and somewhat blunt; the tongue is obtuse, entire, triangular, and very short; and the feet are fitted for walking. There are two species, both natives of India.

URACHUS, a membranous canal in the fœtus of quadrupeds in general, of a pyramidal figure, extended immediately from the fundus of the bladder to the navel; and after passing through this, it is by degrees enlarged, and makes its way into the allantois at right-angles each way, or nearly so, and conveys the urine from the bladder into the cavity of this membrane.

URANBURG, or **URANIENBURG**, a castle of Denmark, situated on the little island of Huen, in the Sound, sixteen miles north-east of Copenhagen. Here was the celebrated observatory built by that noble Dane Tycho Brahe, and furnished with instruments for observing the course and motions of the heavenly bodies.

URANIC.

URANOSCOPUS, in ichthyology, a genus belonging to the order of jugulares. The head is large, rough, and depressed, the upper jaw being shorter than the under one; there are five dentated rays in the membrane of the gills; and the anus is in the middle of the body. There is but one species, found in the Mediterranean sea.

URBINO, a province of Italy, in the pope's territory, bounded by Romania and the gulph of Venice on the north and east, by the marquise of Ancona on the south, and by Tuscany on the west, being seventy miles long, and from twenty to fifty broad.

Urbino is also the capital of this province.

URDE', or **URDE'E**, in heraldry. A cross urde seems to be the same with what we otherwise call chiche, or chleché. See **CHLECHE**.

URENA, in botany, a genus of the monadelphia polyandria class. The calix is double, the exterior one consisting of five segments; the capsule has five cells containing one seed. There are three species, all natives of China.

URETERS, in anatomy. See **ANATOMY**, p. 268.

URETHRA, in anatomy. See **ANATOMY**, p. 272.

URGEL, a town of Spain, in the province of Catalonia, capital of the territory of Urgel, situated on the river Segra, seventy-five miles north of Barcelona.

URI, one of the cantons of Switzerland; bounded by that of Switz, on the north; by Glaris and the Grisons, on the east; by Underwald, on the south; and by the Canton of Bern, on the west.

URIM and **THUMMIM**, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high priest dressed in his robes, and having on his pectoral or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus, and several others, maintain, that it meant the precious stones set in the high priest's breast-plate, which by extraordinary lustre made known the will of God to those who consulted him. Spencer believes that the urim and thummim were two little golden figures shut up in the pectoral as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim as there are particular authors that wrote about them. The safest opinion, according to Broughton, seems to be, that the words urim and thummim signify some divine virtue and power annexed to the breast-plate of the high priest, by which an oracular answer was obtained from God when he was consulted by the high priest; and that this was called urim and thummim to express the clearness and perfection which these oracular answers always carried with them; for urim signifies light, and thummim perfection; these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident. The use made of the urim and thummim was to consult God in difficult cases relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URNAL, in medicine, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons. It is usually of glass, and crooked; and sometimes it is filled with milk, to assuage the pain of the gravel.

URNAL, in chemistry, is an oblong glass vessel, closed for making solutions, and so called from its resemblance to the glasses in which urine is set to settle for the inspection of the physician.

URINE, a ferous and saline fluid, of a citron colour, separated from the blood, and carried by the emulgent arteries to the kidneys, from whence it descends to the bladder by the ureters, and is from time to time emitted thence by the canal of the urethra. See **ANATOMY**, p. 268. For the analysis of urine, see **CHEMISTRY**, p. 177.

URN, a kind of vase, of a roundish form, but biggest in the middle, like the common pithers, now seldom used but in the way of ornament over chimney pieces, in busts, &c. The great use of urns among the ancients, was to preserve the ashes of the dead after they were burnt; for which reason they were called cineraria, and rumæ cinerariæ, and were placed sometimes under the tomb-stone whereon the epitaph was cut; and sometimes in vaults in their own houses. Urns were also used at their sacrifices to put liquid things in.

UROGALLUS, in ornithology. See **TETRAO**.

URSA, in astronomy. See **ASTRONOMY**, p. 487.

URSULINES, in church-history, an order of nuns, founded originally by St Angela of Brescia, in the year fifteen hundred thirty-seven, and so called from St Ursula, to whom they were dedicated. They observe the rules of St Augustine, and are chiefly noted for taking on them the education and instruction of young maids: their monasteries are a kind of schools where young ladies of the best families receive their education.

URSUS, in zoology, a genus of quadrupeds belonging to the order of feræ. There are six foreteeth in the upper jaw alternately hallow on the inside, and six in the under jaw, the two lateral ones being labated; the dog-teeth are solitary and conical; the grinders are five or six; the tongue is smooth; the eyes are furnished with a nictitating membrane; the nose is prominent; and there is a crooked bone in the penis. There are four species, viz. 1. The arctas, or white bear, with an abrupt tail. He is a native of the northern parts of Europe, and feeds upon berries, insects, and the bodies of dead cattle. He is naturally a lazy animal; but when enrag'd, he becomes agile and furious, standing erect and fighting with his forefeet. When lying, he constantly licks his paws. The female admits the male about the end of October, and she brings forth in 112 days. He never attacks a man, unless he be provoked. 2. The meles, has the tail of an uniform colour; the body is ash-coloured above and black below, with a longitudinal black belt across the eyes and ears. He is likewise a native of Europe, and dwells in woods and the clefts of rocks. He feeds upon eggs, insects, the leaves of the lathyrus, &c. In the night he preys upon rabbits, &c. and seldom appears in the day. He thrusts himself up in a den dug in the earth during the winter, and sucks a pellicle or bladder situate above the anus. 3. The lator, has an annular tail, and a black belt across the eyes. He is found about the sea shores of America. He feeds upon eggs, fowls snails, &c. 4. The luscus, has a long tail; and the body is iron coloured. He is a native of Hudson's bay.

URTICA in botany, a genus of the monœcia tetrandria class. The calix of the male consists of four leaves, and that

that of the female of two valves; neither of them have any corolla; the male has a cup-shaped nectarium, and the female bears one smooth seed. The species are 18, three of them natives of Britain, *viz.* the pilafera, or Roman nettle; the arens, or lesser nettle; and the dioica, or common nettle.

USANCE, in commerce, is a determinate time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called because regulated by the usage and custom of the places whereon they are drawn.

USE, in law, the profit or benefit of lands and tenements; or a trust and confidence reposed in a person for the holding of lands, &c. that he to whose use the trust is made shall receive the profits.

USEDOM, an island of Pomerania, in Germany, situated at the mouth of the river Oder, in the Baltic-sea: subject to the king of Prussia.

USHANT, an island of France, fifteen miles west of the coast of Brittany, at the entrance of the British channel.

USHER, an officer, or servant, who has the care and direction of the door of a court, hall, chamber, or the like.

USHER of the black rod, the eldest of the gentlemen ushers, daily waits at court, whose duty is to bear the rod before the king at the feast of St George, and other solemnities.

USK, a river of Wales, which rises on the west of Brecknockshire, and runs south east through that country and Monmouthshire, falling into the mouth of the Severn.

USQUEBAUGH, a strong compound liquor, chiefly taken by way of dram.

There are several different methods of making this liquor; but the following is esteemed one of the best: To two gallons of brandy, or other spirits, put a pound of Spanish-liquorice, half a pound of raisins of the sun, four ounces of currants, and three of dried dates; the tops of baum, mint, savory, thyme, and the tops of the flowers of rosemary, of each two ounces; cinnamon and mace, well bruised, nutmegs, aniseeds, and coriander-seeds, bruised likewise, of each four ounces; of citron, or lemon, and orange-peel, scraped, of each an ounce: let all these infuse forty eight hours in a warm place, often shaking them together: then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it is to be put an equal quantity of neat white port, and a gallon of canary; after which it is to be sweetened with a sufficient quantity of double-refined sugar.

USTION, in pharmacy, the preparing of certain substances by burning them.

USTULATION, a word used by pharmaceutic writers, to express the roasting or torrefying of humid or moist substances over a gentle fire, so as to render them fit for powdering.

USURAPTION, in the civil law, is an acquisition of the property of a thing, by a possession and enjoyment thereof for a certain term of years prescribed by law.

USUFRUIT, in the civil law, the use or enjoyment of any lands or tenements; or the right of receiving the fruits and profits of an inheritance, or other thing, without a power of alienating or changing the property thereof.

USURER a person charged with a habit or act of usury. See *USURY*.

VOL. III. No 99.

USURIOUS CONTRACT, is any bargain or contract where by a man is obliged to pay more interest for money than the statute allows.

USURPATION, in law, is an injurious using or enjoyment of a thing for continuance of time, that belongs of right to another.

USURY, in the general, denotes a gain or profit which a person makes of his money, by lending the same; or it is an increase of the principal, exacted for the loan thereof; or the price a borrower gives for the use of a sum credited to him by the lender, called also interest.

The word usury is generally taken in an evil sense, *viz.* for an unlawful profit which a person makes of his money; in which sense it is, that usury is forbidden by the civil and ecclesiastical, and even by the law of nature. See *LAW*, Tit. xxxiii. 37.

UTERINE, something belonging to the uterus or womb of a woman.

Brother or Sister UTERINE, in Scots law. See *LAW*, Tit. xxvii. 3.

UTERUS, in anatomy. See *ANATOMY*, p 274.

UTILE, a Latin term, signifying profitable or useful; in which sense it is sometimes used by English writers.

UTOXETER, a market-town of Staffordshire, twelve miles south-east of Stafford.

UTRECHT, the capital of a province of the same name, in the united Netherlands, situated twenty three miles south-east of Amsterdam.

UTRICULARIA, in botany, a genus of the diandria monogynia class. The corolla is ringent and calcarated; the calix consists of two equal leaves; and the capsule of one cell. There are five species, two of them natives of Britain, *viz.* the vulgaris, or common hooded milfoil; and the minor, or lesser hooded milfoil.

UVA URSI, in botany. See *VACCINIUM*.

UVEA, in anatomy. See *ANATOMY*, p. 289.

VULCANO, or **VOLECANO**, in natural history, a burning mountain, or one that vomits forth fire, flame, ashes, cinders &c.

As to the cause of vulcanos, it is found by experience, that there are several inflammable bodies, which, being mixed together in due proportion, will kindle into flame by fermentation alone, without the help of any fiery particles. Thus M. Lemery having covered up in the earth about fifty pounds of a mixture, composed of equal parts of sulphur and filings of iron tempered with water; after eight or nine hours time, the earth where it lay vomited up flames. From this experiment we see the true cause of the fire of Ætna, Vesuvius, and other burning mountains, which probably are made up of sulphur and some other matter proper to ferment with it, and take fire.

VULGATE, a very ancient Latin translation of the Bible, and the only one the church of Rome acknowledges authentic. See *BIBLE*.

VULNERARY, in medicine, an epithet given to remedies proper for the cure of wounds and ulcers.

VULPES, the FOX. See *CANIS*.

VULTUR, a genus of birds belonging to the order of accipitres. The beak is straight and crooked at the point, the head has no feathers, on the forehead being only naked skin; and the tongue is bifid.

cies, distinguished principally by their colour and situation of caruncles.

VULVA, in anatomy. See *ANATOMY*, p. 275.

VULVA, in anatomy. See *ANATOMY*, p. 303.

UVULARIA, in botany, a genus of the hexandria monogynia class. The corolla consists of six straight petals; the nectarii are little pits at the base of each petal; and the filaments are very short. There are

three species, none of them natives of Britain. **UXBRIDGE**, a market-town of Middlesex, situated on the river Colne, fifteen miles west of London.

UZBECK, TARTARY, a large country of Asia, bounded by Calmuc Tartary on the north, by Tibet on the east, by India and Persia on the south, and by a great desert, which separates it from the Caspian sea, on the west.

W.

W A G

WAAG, a river of Hungary, which rises in the Carpathian mountains, on the confines of Poland, and running first from east to west, then turns south, and passing by Leopoldstadt, falls into the Danube, opposite to the island of Schut.

WAAL, a river of the United Netherlands, being one of the branches of the Rhine, which runs from east to west, through the Betu, in the province of Guelderland, passing by Nimeguen, Tiel, Bommel, and Gorcum, and continuing its course eastward, unites its waters with the Maes, and, passing by Dort, falls into the German sea below the Briel.

WADD, or WADDING, is a stopple of paper, hay, straw, or the like, forced into a gun upon the powder, to keep it close in the chamber; or to put up close to the shot, to keep it from rolling out.

WADSET, in Scots law. See *LAW*, Tit. xv. 1, &c.

WAFI. To wafi a ship, is to convoy her safe, as men of war do merchant ships. To make a wafi, is to hang out some coat, sea-gown, or the like, on the main shrouds of the ship, as a signal for people to come aboard, and signifying that the ship is in great distress.

WAFERS, or Sealing WAFERS, are made thus: take very fine flower, mix it with glair of eggs, isinglass, and a little yeast; mingle the materials; beat them well together; spread the batter, being made thin with gum-water, on even tin plates; and dry them in a stove; then cut them out for use.

You may make them of what colour you please, by tinging the paste with brazil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAGGON, a wheel-carriage, of which there are various forms, accommodated to the different uses they are intended for. The common waggon consists of the shafts or rads, being the two pieces which the hind horse bears up; the welds; the slogs, or cross pieces, which hold the shafts together; the bolster, being that part on which the fore-wheels and the axle-tree-turn in wheeling the waggon across the road; the chest or body of the waggon, having the staves or rails fixed thereon; the bales, or hoops, which compose the top; the tilt, the place covered with cloth, at the end of the waggon. See *MECHANICS*, p. 50.

W A L

WAGRIA, the eastern division of the duchy of Holstein, in the circle of Lower Saxony, in Germany, bounded by the Baltic sea on the north, east, and south.

WAGTAIL, in ornithology. See *MOTACILLA*.

WAIF, in law, a term applied to such goods as a thief having feloniously stolen, on his being closely pursued are waved or left by the felon, which become forfeited to the king, or lord of the manor.

WAGRATS STRAITS, situated between Nova Zembla and Russia, through which the Dutch sailed to the north, as high as 75°, in order to discover a north-east passage to China and the East Indies.

WAINSCOT, in building, the timber-work that serves to line the walls of a room, being usually made in pannels, and painted, to serve instead of hangings.

WAKE of a ship, is the smooth water astern when she is under sail: this shews the way she has gone in the sea, whereby the mariners judge what way she makes.

WAKE, is the eve-feast of the dedication of churches, which is kept with feasting and rural diversions.

WAKEFIELD, a market-town in the west-riding of Yorkshire, situated on the river Caulder, twenty-four miles south-west of York.

Action of WAKENING, in Scots law. See *LAW*, Tit. xxx. 26.

WALACHIA, a province of Turkey in Europe, bounded by the Irongate mountains, which separate it from Transylvania, on the north-west; by Moldavia, on the north-east; by the river Danube, which separates it from the province of Bulgaria, on the south-east; and the same river separates it from the province of Servia on the south-west. It is two hundred miles long, and one hundred broad.

WALCOURT, a town of the bishopric of Liege, situated on the confines of Namur, eighty miles south of Charleroy.

WALDEC, a town of Germany, in the circle of the Upper Rhine, and landgraviate of Hesse Cassel, twenty miles south-west of Hesse Cassel city.

WALDEN, a market-town of Essex, situated twenty-five miles north-west of Chelmsford.

WALE, or WALES, in a ship, those outermost timbers in a ship's side, on which the sailors set their feet in climbing up. They are reckoned from the water, and are called her first, second, and third wale, or bend.

WALE-

WALE-KNOT, a round knot or knob made with three strands of a rope, so that it cannot slip, by which the tacks, top-sail sheets, and stoppers are made fast, as also some other ropes.

WALE REARED, on board a ship, a name the seamen give to a ship, which, after she comes to her bearing, is built straight up: this way of building, though it does not look well, nor is, as the seamen term it, ship-shapen; yet it has this advantage, that a ship is thereby more roomy within board, and becomes thereby a wholesome ship at sea, especially if her bearing be well laid out.

WALES, a principality in the west of England, comprehending 12 counties, bounded by Cheshire, Shropshire, Herefordshire, and Monmouthshire, on the east, and surrounded by the sea called the Irish channel, on the north, west, and south.

New WALES, the south-west coast of Hudson's Bay, in North America, so called; now possessed by the English Hudson's Bay company.

WALL, in architecture, the principal part of a building, as serving both to inclose it, and support the roof, floors, &c.

Walls are distinguished into various kinds, from the matter whereof they consist, as plastered or mud-walls, brick-walls, stone-walls, flint or boulder walls, and boarded walls. See **ARCHITECTURE**.

WALLINGFORD, a borough-town of Berkshire, situated on the river Thames, twelve miles north of Reading.

WALLOONS, the inhabitants of a considerable part of the Spanish Netherlands, *viz.* those of Artois, Hainault, Namur, Luxembourg, and part of Flanders and Brabant.

The Walloon language is said to have been that of the ancient Gauls or Celts.

WALRUS, in zoology. See **PHOCA**.

WALNUT TREE, in botany. See **JUGLANS**.

WALSALL, a market-town of Staffordshire, thirteen miles south of Stafford.

WALSHAM, a market-town of Norfolk, eleven miles north of Norwich.

WALSINGHAM, a market-town of Norfolk, eighteen miles north-west of Norwich.

WALTHAM, a market town of Leicestershire, sixteen miles north-east of Leicester.

WALTHERIA, in botany, a genus of the monadelphia pentandria class.

WAPENTAKE, (from the Saxon) the same with what we call a hundred, and more especially used in the northern counties beyond the river Trent. There have been several conjectures as to the original of the word; one of which is, that anciently musters were made of the armour and weapons of the inhabitants of every hundred; and from those that could not find sufficient pledges of their good bearing, their weapons were taken away, and given to others; whence, it is said, this word is derived. See **HUNDRED**.

WAR, a contest or difference between princes, states, or large bodies of people; which not being determined by the ordinary measures of equity and justice, is referred to the decision of the sword.

WARD, a word of divers significations: thus, a ward in London, is a part of the city committed to the special charge of one of the aldermen of the city. There are twenty-six wards in London, which are as hundreds, and

the parishes thereof as towns. A forest is also divided into wards, and so are most of our hospitals.

WARD-HOLDING, in Scots law. See **LAW**, Tit. xi. 1.

WARD-HOOK, or **WADD-HOOK**, in gunnery, a rod or staff with an iron end turned serpent-wise, or like a screw, to draw the wadding out of a gun when it is to be unloaded. See **WADD**.

WARDEN, or **GUARDIAN**, one who has the charge or keeping of any person, or thing, by office. See **GUARDIAN**.

Such is the warden of the fleet, the keeper of the fleet-prison; who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

Church WARDENS. See **CHURCH**.

WARDHUIS, a port of Norwegian Lapland, 120 miles south-east of the north-cape: E. long. 28°, and N. lat. 71°.

WARDMOTE, in London, is a court so called, which is kept in every ward of the city, answering to the curiata comitia in ancient Rome.

WARDROBE, a closet, or little room adjoining to a bed-chamber, serving to dispose and keep a person's apparel in; or, for a servant to lodge in, to be at hand to wait, &c.

Wardrobe, in a prince's court, is an apartment where-in his robes, wearing apparel, and other necessaries, are preserved under the care and direction of proper officers; as the master of the wardrobe, clerk, &c. of the wardrobe.

WARE, a market-town of Hertfordshire, under the meridian of London, and twenty miles north of that city.

WAREHAM, a borough of Dorsetshire, seventeen miles east of Dorchester.

WARMINSTER, a market-town of Wiltshire, seventeen miles north-west of Salisbury.

WARN, in law, is to summon a person to appear in a court of justice.

WARNING of Tenants, in Scots law. See **LAW**, Tit. xiii. 16.

WARP, in the manufactures, is the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and a-crofs which the workman by means of his shuttle passes the threads of the woof, to form a cloth, ribband, fustian, or other matter.

WARRANTICE, in Scots law. See **LAW**, Tit. x. 11.

WARRANT, an act, instrument, or obligation, whereby a person authorises another to do something which he otherwise had not a right to do.

WARRANTY, a promise or covenant by deed, made by the bargainer for himself and his heirs, to warrant and secure the bargainee and his heirs against all men for enjoying the thing agreed on between them.

WARREN, a franchise, or place privileged either by prescription or grant from the king, to keep beasts and fowl of warren in: as rabbits, hares, partridges, pheasants, &c.

WARRINGTON, a market-town of Lancashire, seventeen miles east of Liverpool.

WARSAW, the capital of Warovia, and of the kingdom of Poland: E. long. 21° 5', and N. lat. 52° 15'.

WARSOVIA, a province of Poland, bounded by Prussia, on the north; by Polachia, on the east; by the province of Little Poland, on the south; and by that of Great Poland, on the west.

WART,

WART, in surgery, a little round hard excrecence arising from the flesh like a pea.

WARWICK, the capital of Warwickshire, situated on the river Avon, eighty miles north-west of London: W. long. $1^{\circ} 32'$, N. lat. $52^{\circ} 20'$.

WASH, among distillers, the fermentable liquor used by the malt-distillers. See BREWERY.

WASHING, in painting, is when a design, drawn with a pen or crayon, has some one colour laid over it with a pencil, as Indian ink, bistre, or the like, to make it appear the more natural, by adding the shadow of prominences, aperture, &c. and by imitating the particular matters whereof the thing is supposed to consist.

Thus they wash with a pale red, to imitate brick and tile; with a pale Indian-blue, to imitate water and slate; with green, for trees and meadows; with saffron or

French berries, for gold or brassy; and with several colours, for marbles.

WASHING of Ores, the purifying an ore of any metal, by means of water, from earths and stones, which would otherwise render it difficult of fusion. See CHEMISTRY, p. 130.

WASP, in zoology. See VESPA.

WASTE of a Ship, is that part of her between the main and fore mast.

WASTE-BOARDS, are boards sometimes set upon the side of a boat, or other vessel, to keep the sea from breaking into her.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrol.

WATCH and CLOCK WORK.

A CLOCK is a machine constructed in such a manner, and regulated by such uniform movements, as to measure time and all its subdivisions with great exactness. The same definition comprehends watches of all kinds; and indeed they are both made upon the same principles. We shall therefore give a view of the construction of both these machines under this article.

Of the Mechanism of Clocks, and how they measure Time.

THE first figure of Plate CLX is a profile of a clock; P is a weight suspended by a rope that winds about the cylinder or barrel C, which is fixed upon the axis *a a*; the pivots *b b* go into holes made in the plates TS, TS, in which they turn freely. These plates are made of brass or iron, and are connected by means of *four pillars ZZ*; and the whole together is called the frame.

The weight P, if not restrained, would necessarily turn the barrel C with an uniform accelerated motion, in the same manner as if the weight was falling freely from a height. But the barrel is furnished with a ratchet wheel K K, the right side of whose teeth strikes against the click, which is fixed with a screw to the wheel D D, as represented in fig. 2. so that the action of the weight is communicated to the wheel D D, the teeth of which act upon the teeth of the small wheel *d* which turns upon the pivots *c c*. This communication of the teeth of one wheel with another is called engrainage or pitching; and a small wheel, like *d*, is called a pinion.

The wheel E E is fixed upon the axis of the pinion *d*; and the motion communicated to the wheel D D by the weight is transmitted to the pinion *d*, consequently to the wheel E E, as likewise to the pinion *e*, and wheel F F, which moves the pinion *f*, upon the axis of which the crown or balance wheel G H is fixed. The pivots of the pinion *f* play in holes of the plates L M, which are fixed horizontally to the plates T S. In a word, the motion begun by the weight is transmitted from the wheel G H to the palettes I K, which communicates its motion by means of the fork U X riveted upon the palettes, to the pendulum A B, which is suspended upon the hook A. The pendulum A B describes, round the point A, an arc of a circle alternately going and re-

turning. If then the pendulum be once put in motion by a push of the hand, the weight of the pendulum at B will make it return upon itself, and it will continue to go alternately backward and forward till the resistance of the air upon the pendulum, and the friction at the point of suspension at A, destroys the original impressed force. But as, at every vibration of the pendulum, the teeth of the balance-wheel G H act upon the palettes I K, (the pivots upon the axis of these palettes play in two holes of the potence *e t*;) that after one tooth H has communicated motion to the palette K, that tooth escapes; then the opposite tooth G acts upon the palette I, and escapes in the same manner; and thus each tooth of the wheel escapes the palettes I, K, after having communicated their motion to the palettes in such a manner that the pendulum, instead of being stopped, continues to move.

The wheel E E revolves in an hour; the pivot *c* of this wheel passes through the plate, and is continued to *r*; upon the pivot is a wheel N N with a long socket fastened in the centre; upon the extremity of this socket *r* the minute-hand is fixed. The wheel N N acts upon the wheel O; the pinion of which, *p*, acts upon the wheel *g g*, fixed upon a socket which turns along with the wheel N. This wheel *g g* makes its revolution in 12 hours, upon the barrel of which the hour-hand is fixed.

From the above description it is easy to see, 1. That the weight *p* turns all the wheels, and at the same time continues the motion of the pendulum. 2. That the quickness of the motion of the wheels is determined by that of the pendulum. 3. That the wheels point out the parts of time divided by the uniform motion of the pendulum.

When the cord upon which the weight is suspended is entirely run down from off the barrel, it is wound up again by means of a key, which goes on the square end of the arbor at Q, by turning it in a contrary direction from that in which the weight descends. For this purpose, the inclined side of the teeth of the wheel R (fig. 2) removes the click C, so that the ratchet-wheel R turns while the wheel D is at rest: But as soon as the cord is wound up, the click falls in between the teeth of the wheel D and the right side of the teeth again act upon the end of the click, which obliges the

HH, (fig. 4.) The pivot I, in the end of the verge, enters into the hole *e* in the potance A (fig. 5.) In this figure the palettes are represented; but the balance is on the other side of the plate, as may be seen in fig. 11. The pivot 3 of the balance enters into a hole of the cock BC, (fig. 10.) a perspective view of which is represented in (fig. 12.) Thus the balance turns between the cock and the potance *c*, (fig. 5.) as in a kind of cage. The action of the balance-wheel upon the palettes 1, 2, (fig. 4.) is the same with what we have described with regard to the same wheel in the clock; *i. e.* in a watch the balance-wheel obliges the balance to vibrate backwards and forward like a pendulum. At each vibration of the balance a palette allows a tooth of the balance-wheel to escape, so that the quickness of the motion of the wheels is entirely determined by the quickness of the vibrations of the balance, and these vibrations of the balance and motion of the wheels are produced by the action of the spring.

But the quickness or slowness of the vibrations of the balance depend not solely upon the action of the great spring, but chiefly upon the action of the spring *a, b, c*, called the spiral spring, (fig. 14.) situated under the balance H, and represented in perspective (fig. 11.) The exterior end of the spiral is fixed to the pin *a*, (fig. 14.)

This pin is applied near the plate in *a*, (fig. 11.) the interior end of the spiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itself, the plates remaining immovable, the spring will extend itself, and make the balance perform one revolution. Now, after the spiral is thus extended, if the balance be left to itself, the elasticity of the spiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

In fig. 7. all the wheels above described are represented in such a manner, that you may easily perceive at first sight how the motion is communicated from the barrel to the balance.

In fig. 8. are represented the wheels under the dial-plate by which the hands are moved. The pinion *a* is adjusted to the force of the prolonged pivot of the wheel D, (fig. 7.) and is called a cannon pinion. This wheel revolves in an hour. The end of the axis of the pinion *a*, upon which the minute-hand is fixed, is square; the pinion (fig. 8.) is indented into the wheel *b*, which is carried by the pinion *a*. Fig. 9. is a wheel fixed upon a barrel, into the cavity of which the pinion (*a*) enters, and upon which it turns freely. This wheel, (*d*) revolves in 12 hours, and carries along with it the hour-hand.

W A T

WATCHING, in medicine, is produced by too great a determination of the nervous fluid to the organs of the senses; whereby these organs are prepared to receive, readily, any impressions from external objects, which they propagate to the brain, and furnish the soul with divers occasions of thinking. See **MEDICINE**, p. 157.

WATER, in physiology, a simple fluid, and liquid body, reputed the third of the four vulgar elements. See **CHEMISTRY**, p. 67. and **HYDROSTATICS**.

Holy WATER, a water prepared every Sunday in the Romish church, with divers prayers, exorcisms, &c. used by the people to cross themselves withal at their entrance to and going out of church; and pretended to have the virtue of washing away venial sins, driving away devils, preserving from thunder, dissolving charms, securing from, or curing diseases, &c. Many of the reformed take the use of holy water to have been borrowed from the lustful water of the ancient Romans.

WATER ORDEAL, or TRIAL, among our ancestors, was of two kinds, by hot and by cold water. Trial or purification, by boiling or hot water, was a way of proving crimes, by immersing the body, or the arm, in hot water, with divers religious ceremonies. In the judgment by boiling water, the accused, or he who personated the accused, was obliged to put his naked arm into a caldron full of boiling water, and to draw out a stone thence placed at a greater or less depth, according to the quality of the crime. This done, the arm was wrapped up, and the judge set his seal on the cloth; and at the end of three days they returned to view it; when if it were found without any scald, the accused was declared innocent. The nobles or great personages purged themselves thus by hot water, and the populace by cold water. The trial, or purification, by cold water, was thus: After certain prayers and other ceremonies, the accused was swaddled or tied

W A T

up all in a peloton or lump, and thus cast into a river, lake, or vessel of cold water; where if he sunk, he was held criminal; if he floated, innocent.

In the Levitical law, we find mention made of water which served to prove whether or no a woman was an adulteress; the formula, as it was performed by the priest, may be seen in the fifth chapter of the book of Numbers.

WATER, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

WATER-Beetle, in zoology. See **DYTISCUS**.

WATER-BORNE, in the sea-language. A ship is said to be water-borne, when she is where there is no more water than will barely bear her from the ground; or when lying even with the ground, she first begins to float or swim.

WATER-COLOURS, in painting, are such colours as are only diluted and mixed up with gum-water, in contradistinction to oil-colours.

WATER-GANG, a channel cut to drain a place by carrying off a stream of water.

WATER-LINE of a Ship, a line which distinguishes that part of her under water from that above, when she is duly laden.

WATER-MEN, are such as row in boats, or ply on the river Thames, in the government of whom the lord-mayor of London, and court of aldermen there, had always great power. They still have the appointing of their fares, the taking more than which makes them liable to a fine of 40s. and half a year's imprisonment.

WATER-SHOOT, a young spring which springs out of the root or stock of a tree.

WATER-SHOT, in the sea-language, a sort of riding at anchor, when a ship is moored neither over the tide, nor right up and down, but quartering betwixt both.

WATER-TABLE, in architecture, a sort of ledge left in stone

Fig. 1.

stone or brick-walls, about eighteen or twenty inches from the ground, from which place the thickness of the wall begins to abate.

WATER-WAY, in a ship, is a small ledge of timber, lying fore and aft on the deck, clove by her sides, to keep the water from running down there.

WATER-WORKS, in general, denote all manner of machines moved by, or employed in raising or sustaining water; in which sense, water-mills of all kinds, sluices, aqueducts, &c. may be called water-works. See **HYDROSTATICS**.

WATERFORD, a port-town of Ireland, capital of the county of Waterford, situated on the river Suir, eight miles north of the sea: W. long 7° , N. lat. $52^{\circ} 12'$.

It is one of the largest cities in Ireland, and has a good foreign trade.

WATERING, in the manufactures, is to give a lustre to stuffs, &c. by wetting them lightly with gum-water, and then passing them through the press, or calender, whether hot or cold.

The gum-water ought to be pure, thin, and clear, otherwise the folds of the stuff will stick together: the operation must also be performed when the water is very hot, that it may penetrate.

WATLINGTON, a market-town of Oxfordshire, situated twelve miles south-east of Oxford.

WATTON, a market-town of Norfolk, sixteen miles south-west of Norwich.

WAVE, in philosophy, a cavity in the surface of water, or other fluid, with an elevation aside thereof.

The waves of the sea are of two kinds, natural and accidental. The natural waves are those which are exactly proportioned in size to the strength of the wind, whose blowing gives origin to them. The accidental waves are those occasioned by the wind's re-acting upon itself by repercussion from hills and mountains, or high shores, and by the washing of the waves themselves, otherwise of the natural kind, against rocks and shoals: all these causes give the waves an elevation, which they can never have in their natural state.

Mr. Boyle has proved, by numerous experiments, that the most violent wind never penetrates deeper than six feet into the water; and it should seem a natural consequence of this, that the water moved by it can only be elevated to the same height of six feet from the level of the surface in a calm: and this six feet of elevation being added to the six of excavation, in the part whence that water so elevated was raised, should give twelve feet for the utmost elevation of a wave. This is a calculation that does great honour to its author; for count Marigli measured carefully the elevation of the waves near Provence, and found, that, in a very violent tempest, they arose only to seven feet above the natural level of the sea, and this additional foot in height he easily resolved into the accidental shocks of the water against the bottom, which was, in the place he measured them in, not so deep as to be out of the way of affecting the waves; and he allows that the addition of one sixth of the height of a wave, from such a disturbance from the bottom, is a very moderate alteration from what would have been its height in a deep sea; and concludes, that Mr. Boyle's calculation holds perfectly right in deep seas, where the waves are purely natural, and have no accidental causes to render them

larger than their just proportion. In deep water, under the high shores of the same part of France, this author found the natural elevation of the waves to be only five feet; but he found also, that their breaking against rocks, and other accidents to which they were liable in this place, often raised them to eight feet high.

We are not to suppose, from this calculation, that no wave of the sea can rise more than six feet above its natural level in open and deep water; for waves immensely higher than these are formed, in violent tempests, in the great seas. These, however, are not to be accounted waves in their natural state; but they are single waves formed of many others: for in these wide plains of water, when one wave is raised by the wind, and would elevate itself up to the exact height of six feet, and no more, the motion of the water is so great, and the succession of the waves so quick, that, during the time this is rising, it receives into it several other waves, each of which would have been at the same height with itself; these run into the first wave, one after another, as it is rising; by this means its rise is continued much longer than it naturally would have been, and it becomes terribly great. A number of these complex waves arising together, and being continued in a long succession by the continuation of the storm, make the waves so dangerous to ships, which the sailors in their phrase call mountains-high.

WAVE-OFFERING, in Jewish antiquity, a sacrifice offered by agitation, or waving, towards the four cardinal points of the compass.

WAVED, in heraldry, is said of a bordure, or any ordinary, or charge, in a coat of arms, having its outlines indented in manner of the rising and falling of waves: it is used to denote, that the first of the family in whose arms it stands, acquired its honours for sea-service.

WAVING, in the sea-language, is the making signs to a vessel to come near or keep off.

WAX, or *Bees-Wax*, in natural history, a firm and solid substance, moderately heavy, and of a fine yellow colour, formed by the bees from the farina of flowers. See **ARIS**.

The best sort is that of a lively yellow colour, and an agreeable smell, somewhat like that of honey: when new, it is toughish, yet easy to break; but by age it becomes harder and more brittle, loses its fine colour, and in a great measure its smell.

From the common yellow wax, by the mere effect of sun and air, or by what is called bleaching, is formed what we term white-wax, and some, very improperly, virgin-wax. The greater the surface is in proportion to the quantity, the sooner and more perfectly this operation is performed. The usual way is to melt the wax in hot water; when melted, they press it through a strainer of tolerable fine linen, and pour it into round and very shallow moulds. When hardened by cooling, it is taken out and exposed to the sun and air, sprinkling it now and then with water, and often turning it: by this means it soon becomes white. The best sort is of a clear and almost transparent whiteness, dry, hard, brittle, and of an agreeable smell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great use both in medicine and in many of the arts and manufactures. It is sometimes given internally, as in dysenteries, and other erosions

erofions of the intellines; but its great ufe is in the making ointments and plasters for external ufe, and the greater part of thofe of the fhops owe their confiftence to it. The white-wax is alfo an ingredient in fome of the cerates and ointments of the fhops; and is ufed in making candles, and in many of the nicer arts and manufactures, where wax is required.

Sealing-Wax is made in the following manner: Take one pound of bees-wax; three ounces of fine turpentine; olive-oil, and rofin, finely powdered, of each one ounce: when they are well melted, and the dregs taken off, put in an ounce and a half of vermilion, or red-lead, finely ground, and ftir them together till they are well incorporated: and when this mixture grows a little cool, roll it into ficks, or in any other form. If you would have it black, inftead of vermilion, or red-lead, put in lamp-black. The foft, red, and green-wax, ufed in large feals to fome of our law-writings, are thus made: Melt bees-wax over a gentle heat, with fuch a proportion of Venice turpentine as, when cold, will give it the due confiftence: this is determined by repeated trials, firft putting in but little turpentine, and afterwards more and more, till by dropping a piece upon a marble to cool, it is found of the true confiftence. They then colour it with red-lead, or vermilion, or with verditer, or whatever colours they pleafe, the mixture in this ftate receiving any.

WAX-work, the representation of the faces, &c. of perfon living or dead; made by applying plafter of Paris in a kind of paffe, and thus forming a mould containing the exact representation of the features. Into this mould melted wax is poured, and thus a kind of mafs are formed; which being painted and fet with glafs eyes, and the figures drefsed in their proper habits, they bear fuch a refemblance that it is difficult to diftinguifh between the copy and the original.

WAY, a paffage or road.

The Roman ways are divided into confular, prætorian, military, and public; and of thefe we have four remarkable ones in England: the firft, Watling-ftreet, or Watling-ftreet, leading from Dover to London, Dunftable, Toucefter, Atterfton, and the Severn, extending as far as Anglefea in Wales. The fecond, called Hikenild, or Ikenild-ftreet, ftretches from Southampton over the river Ifis at Newbridge; thence by Camden and Litchfield; then paffes the Derwent, near Derby, and ends at Tintmouth. The third, called Foffe-way, becaufe in fome places it was never perfected, but lies as a large ditch, leads from Cornwall through Devonfhire, by Tethbury, near Stow in the Wolds; and befide Coventry to Leicefter, Newark, and fo to Lincoln. The fourth, called Erming, or Erminage-ftreet, extends from St. David's, in Wales, to Southampton.

Way of a fhip, is fometimes the fame as her rake, or run forward or backward: but this term is moft commonly underftood of her failing.

Way-wode, a title given to the governors of the chief places in the empire of Mulcory, as alfo in Poland.

WEAR, or **WEER**, a great ftank or dam in a river, fitted for the taking of fifh, or for conveying the ftream to a mill.

New wears are not to be made, or others altered, to the nufance of the public, under a certain penalty.

WEASEL, in zoology. See **MUSTELA**.

WEATHER, the ftate or difpofition of the atmofphere with regard to heat, cold, wind, rain, froft, &c.

As it is in the atmofphere that all plants and animals live, and as that appears to be the great principle of moft animal and vegetable productions, alterations, &c. there does not feem any thing, in all philofophy, of more immediate concernment to us than the ftate of the weather, and a knowledge of the great influence it has on our bodies. What valt, but regular, alterations a little turn of weather makes in a tube filled with mercury, or fpirits of wine, or in a piece of ftring, &c. every body knows, in the common ufe of barometers, thermometers, &c. and it is owing partly to our inattention, and partly to our unequal and intemperate courfe of living, that we do not feel as great and regular ones in the tubes, chords, and fibres of our own bodies.

WEATHER-COCK, a moveable vane in form of a cock, or other fhape, placed on high, to be turned round according to the direction of the wind, and point out what quarter the wind blows from,

WEATHER-GLASSES. See **BAROMETER**, and **THERMOMETER**.

WEATHERING, among failors, fignifies the doubling, or failing by a head-land, or other place.

WEAVING, the art of working a web of cloth, filk, or other ftuff, in a loom with a fhuttle. For the manner of performing which, fee **CLOTH**.

WEB, a fort of tifue or texture formed of threads interwoven with each other; fome whereof are extended in length, and called the warp; and others drawn acrofs, and called the woof. See **CLOTH**.

Spider's WEB. See **ARANEÆ**.

WEDGE, one of the mechanical powers. See **MECHANICS**.

WEDNESDAY, the fourth day of the week, fo called from a Saxon idol named Woden, fuppofed to be Mars, worfhipped on this day.

A/b-**WEDNESDAY**, the firft day of Lent, fo called from the cuftom obferved in the ancient christian church of penitents expreffing their humiliation at this time, by appearing in fackcloth and afhes.

WEED, a common name for all rank and wild herbs, that grow of themfelves, to the detriment of other ufeful herbs they grow among.

WEED, in the miners language, denotes the degeneracy of a load or vein of fine metal into an ufelefs mafcafite.

WEEK, in chronology, a divifion of time comprifing feven days. See **ASTRONOMY**, p. 489.

The origin of this divifion of weeks, or of computing time by fevenths, is greatly controverted. Some will have it to take its rife from the four quarters or intervals of the moon, between her changes or phases, which, being about feven days diftant, gave occafion to the divifion.

Be this as it will, the divifion is certainly very ancient. The Syrians, Egyptians, and moft of the oriental nations, appear to have ufed it from all antiquity: though it did not get footing in the weft till Chriftianity brought it in: the Romans reckoned their days no by fevenths, but by ninths, and the ancient Greeks by decads or tenths.

Indeed, the Jews divided their time by weeks, but it was upon a different principle from the eastern nations. God

God himself appointing them to work six days, and to rest the sabbath, in order to keep up the sense and remembrance of the creation; which being effected in six days, he rested the seventh.

PASSION WEEK, or the *Holy WEEK*, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

WYCK, or **WYCK**, in geography, a parliament and port-town of Scotland, in the shire of Cathness: W. long. 2° 45'. N. lat. 58° 40'.

WEEVER, in ichthyology. See **TRACHINUS**.

WEIGH, a weight of cheese, wool, &c. containing 256 pounds avoirdupoise. Of corn, the weigh contains for ty bushels: of barley or malt, six quarters. In some places, as Essex, the weigh of cheese is 300 pounds.

WEIGHING, the act of examining a body in the balance to find its weight.

WEIGHING-ANCHOR, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

WEIGHT, in physics, a quality in natural bodies whereby they tend downwards, towards the centre of the earth. Or, weight may be defined, in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point called the centre of gravity; and that with a greater or less velocity, as they are more or less dense, or as the medium they pass thro' is more or less rare. See **MECHANICS**.

WEIGHT, in commerce, denotes a body of a known weight, appointed to be put in the balance against other bodies whose weight is required.

WELL, or **WEL**, an imperial city of Germany, in the circle of Swabia, and duchy of Wirtemberg: E. long. 8° 40'. N. lat. 48° 40'.

WEIMAR, a city of Germany, in the circle of Upper Saxony, the capital of the Weimar: E. long. 11° 25'. N. lat. 51°.

WEISEL, a river of Poland, and the same with the *Vistula*. See **VISTULA**.

WEISSENBURG, or **STULWEISSENBURG**, a city of Lower Hungary, situated near the east end of the Platten sea, thirty-six miles south-west of Buda.

WEISSENFELD, a town of Germany, in the circle of Upper Saxony, and marquisate of Misnia, seventeen miles south-west of Leipzig.

WELCH-OLE, a market-town of Montgomeryshire, situated six miles north of Montgomery.

WELD, or **WOLD**, in botany. See **RESEDA**.

WELDING HEAT in smithery, a degree of heat given to iron, &c. sufficient only for bending, or doubling it up.

WELL, a hole under ground, usually of a cylindrical figure, and walled with stone and mortar: its use is to collect the water of the strata around it.

WELL in the military art, a depth which the miner sinks under ground with branches or galleries running out from it: either to prepare a mine, or to discover and disappoint the enemies mine.

WELL HOLE in building, is the hole left in a floor for the stairs to come up through.

WELLS, a city of Somersetshire, situated sixteen miles south-west of the city of Bath, both which cities have but one bishop.

This is also the name of a town of Germany, in the circle of Austria, situated eleven miles south of Linz.

WELLAND, a river which rises in Leicestershire, and running eastward between the counties of Rutland and Northampton, and afterwards north-east by Stamford, falls into a bay of the German Sea, which divides the counties of Lincoln and Norfolk.

WELLINBOROUGH, a market-town of Northamptonshire, situated on the river Nen, ten miles north-east of Northampton.

WELLINGTON, a market-town of Shropshire, situated ten miles east of Shrewsbury.

WEM, a market-town of Shropshire, situated eight miles north of Shrewsbury.

WEN, a tumour or excrescence that arises on different parts of the body, and contains a cystus or bag filled with some peculiar matter.

WENDOVER, a borough town of Bucks, six miles south of Aylesbury, which sends two members to parliament.

WENER, a lake in Sweden, in the province of Gothland, seventy miles in length, and fifty in breadth.

WENLOCK, a borough-town of Shropshire, ten miles south-east of Shrewsbury; which sends two members to parliament.

WENSUSSEL, the north division of Jutland, in Denmark, having the Categate sea on the north, the Schagerrack sea on the east, the province of Wiburg on the south, and the German Sea on the west.

WEOBLEY, a borough-town of Herefordshire; 12 miles north-west of Hereford; which sends two members to parliament.

WERMELAND, a province of Sweden, lying between the province of Dalecarlia on the north, and the lake Wener on the south.

WESEL, a city of Germany, in the duchy of Cleves: E. long. 6° 5'. N. lat. 51° 37'.

WESER, a river of Germany, which rises in the Landgrate of Hesse, runs between the circles of Westphalia and Lower Saxony, and falls into the German sea below Carlsstat.

WEST, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defined, the intersection of the prime vertical with the horizon, on that side the sun sets in.

WESTRURY, a borough town of Wiltshire, twenty miles north-west of Salisbury; which sends two members to parliament.

WESTLOW, a borough-town of Cornwall, twenty-three miles south-west of Launceston; which sends two members to parliament.

WESTMANIA, a province of Sweden, having Upland on the east, and Wetmeland on the west.

WESTMEATH, a county of Ireland, in the province of Leinster, bounded by Longford and Cavan on the north; by Eastmeath, on the east; by King's County, on the south; and by the river Shannon, which divides it from Roscommon, on the west.

WESTMINSTER, a city which forms the west part of the town which goes by the general name of London; but is under a distinct government; the dean and chapter appointing the high steward, high bailiff, and other officers, who have the government of the city. Here are the king's palaces, and the houses of most of the nobility.

bility, the high court of parliament, and the supreme courts of justice; but there is no bishop of this city. It elects two members of parliament.

WESTMORELAND, an English county, bounded by Cumberland on the north, by Yorkshire on the east, by Lancashire on the south, and by the Irish channel on the west.

WESTPHALIA, the north-west circle of the empire of Germany; bounded by the German ocean, on the north; by the circle of Lower Saxony, on the east; by the Landgrate of Hesse, the Palatinate of the Rhine, and the electorate of Triers, on the south; and by the Netherlands, on the west: being 200 miles in length, and from 150 to 200 in breadth.

WESTRAM, a market town of Kent, under the meridian of London, 44 miles west of Canterbury.

WETTERAVIA, the southern division of the Landgrate of Hesse, in Germany, lying along the northern bank of the river Maine, comprehending the counties of Hanau and Nassau.

WETZLAR, an imperial city of Germany, in the circle of the Upper Rhine and territory of Wetteravia, situated on the river Lahn, E. long. $8^{\circ} 15'$, N. lat. $50^{\circ} 30'$.

WEXFORD, a county of Ireland, in the province of Munster, bounded by the county of Wicklow on the north, by the ocean on the east and south, and by Kilkenny and Waterford on the west.

Wexford, the capital of this county, is situated at the mouth of the river Slaney, sixty five miles south of Dublin.

WEYMOUTH, a port-town of Dorsetshire, situated on a fine bay of the English channel, seven miles south of Dorchester. It sends two members to parliament.

WHALE, in ichthyology. See **BALÆNA**, and **PHYSETER**.

WHARF, a space on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading of vessels upon.

WHEAT, in botany. See **TRITICUM**. For the culture of wheat, see **AGRICULTURE**, p. 60.

WHEEL, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis. See **MECHANICS**.

WHELP, the young of a dog, fox, lion, or any wild beast.

WHELPS, in a ship, the seaman's term for those brackets which are set up on the capstan close under the bars; they give the sweep to it, and are so contrived that the cable winding about them may not surge so much as it might otherwise do if the body of the capstan were quite round and smooth.

WHETSTONE, a stone which serves for the whetting of knives and other tools upon.

WHEY, the serum, or watery part, of milk. See **WHEY**.
WHIG, a party in Britain, opposite to the tories, from whom they differ chiefly in their political principles. See **TORIES**.

The names of whig and tory were not known till about the middle of the reign of Charles II. when these were given as party distinctions. These parties may be considered either with regard to the state, or to religion. The state tories are either violent, or moderate: the first would have the king to be absolute, and therefore plead

for passive obedience, non-resistance, and the hereditary right of the house of Stuart. The moderate tories would not suffer the king to lose any of his prerogative; but then they would not sacrifice those of the people. The state whigs are either strong republicans, or moderate ones. The first, says Rapin, are the remains of the party of the long parliament, who attempted to change monarchy to a commonwealth; but these make so slender a figure, that they only serve to strengthen the party of the other whigs. The tories would persuade the world, that all the whigs are of this kind; as the whigs would make us believe that all the tories are violent. The moderate state-whigs are much in the same sentiments with the moderate tories, and desire that the government may be maintained on the ancient foundation: all the difference is, that the first bear a little more to the parliament and people, and the latter to that of the king. In short, the old whigs were always jealous of the encroachments of the royal prerogative, and watchful over the preservation of the liberties and properties of the people.

WHIP, or **WHIP-STAFF**, in a ship, a piece of timber, in form of a strong staff, fastened into the helm, for the steersman, in small ships, to hold in his hand, in order to move the rudder and direct the ship.

WHIRLPOOL, an eddy, vortex, or gulph, where the water is continually turning round.

These in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears, it is very furious; and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out: this substance, whatever it be, is immediately received into the centre, and carried under water; and as soon as this is done, the surface of the place where the whirlpool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile's distance from the first.

WHIRLWIND, a wind that rises suddenly, is exceeding rapid and impetuous when risen, but is soon spent. See **PNEUMATICS**, p. 495.

WHISPERING. See the articles **HEARING**, **ATTENTION**, &c.

WHISPERING PLACES depend upon this principle. If the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis, and by that means prevented from spreading, till they get out of it; whereby they will be exceedingly increased, and the sound rendered much louder than it would otherwise be.

Hence it is that sound is conveyed from one side of a whispering gallery to the opposite one, without being perceived by those who stand in the middle.

WHIST,

India company, situated on the western branch of the river Ganges, in the province of Bengal: E. long. 87°, N. lat. 27° 45'.

WILLIAMSTAT, a port-town of Holland, situated on the sea called Hollands-Deep, fourteen miles south of Rotterdam.

WILLOW, in botany. See **SALIX**.

WILNA, a city of Poland capital of the great duchy of Lithuania, situated on a river of the same name: E. long 25° 15', N. lat 55°.

WILTON, a borough-town of Wiltshire, situated on the river Willey, six miles north-west of Salisbury. It sends two members to parliament.

WILTSHIRE, a county of England, bounded by Gloucestershire and Oxfordshire on the north, by Berkshire and Hampshire on the east, by Dorsetshire on the south, and by Somersetshire on the west.

WINCHELSEA, a borough and port-town of Suffex, situated on a bay of the English channel, thirty miles east of Lewes. It sends two members to parliament.

WINCHESTER, the capital city of Hampshire, situated on the river Itchen, sixty-five miles south-west of London.

WIND. See **PNEUMATICS**, p. 495.

WIND MILL, a kind of mill, the internal parts of which are much the same with those of a water-mill; from which however it differs, in being moved by the impulse of the wind upon its vanes, or sails, which are to be considered as a wheel on the axle. See **MECHANICS**.

WIND-FLOWER, in botany. See **ANEMONE**.

WIND GALL, a name given by our farmers to a distemper of horses. See **FARRIERY**, p. 575.

WIND SAILS, in a ship, are made of the common sail cloth, and are usually between twenty-five and thirty feet long, according to the size of the ship, and are of the form of a cone ending obliquely: when they are made use of, they are hoisted by ropes to about two thirds or more of their height, with their basis distended circularly by hoops, and their apex hanging downwards in the hatch ways of the ship; above each of these, one of the common sails is so disposed, that the greatest part of the air rushing against it, is directed into the wind-sail, and conveyed, as through a funnel, into the upper parts of the body of the ship.

WIND TACKLE BLOCKS, in a ship, are the main double blocks, which being made fast to the end of a small cable, serve for hoisting of goods into the ship, &c.

To WIND, or **WEND** a ship, signifies to bring her head about. *How winds or wends the ship?* is a question asked by mariners, concerning a ship under sail; signifying as much as, upon what point of the compass does she lie with her head?

WINDWARD, in the sea-language, denotes any thing towards that point from whence the wind blows, in respect of a ship: thus windward-tide, is the tide which runs against the wind.

WINDAGE of a gun, the difference between the diameter of the bore, and the diameter of the ball.

WINDLASS, a machine used to raise huge weights withal, as guns, stones, anchors, &c.

It is very simple, consisting only of an axis, or roller, supported horizontally at the two ends, by two pieces of wood and a pulley: the two pieces of wood meet at top,

being placed diagonally so as to prop each other; the axis, or roller, goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two flaves or hand-pikes which go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

WINDLASS, in a ship, is an instrument in small ships, placed upon the deck, just abast the fore mast. It is made of a piece of timber six or eight feet square, in form of an axle-tree, whose length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of hand-pikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those that heave; for if in heaving the windlass about, any of the hand-pikes should happen to break, the windlass would fall of itself.

WINDOW, an aperture or open place in the wall of a house, to let in the wind and light. See **ARCHITECTURE**, p. 357.

WINDSOR, a borough-town of Berkshire, twenty miles west of London, most remarkable for the magnificent palace or castle situated there on an eminence, which commands the adjacent country for many miles, the river Thames running at the foot of the hill. The knights of the garter are installed in the royal chapel here. It sends two members to parliament.

WINE, a brisk, agreeable, spirituous and cordial liquor, drawn from vegetable bodies, and fermented.

All sorts of vegetables, fruits, seeds, roots, &c. afford wine; as grapes, currants, mulberries, elder-berries, cherries, apples, pulse, beans, pease, turneps, radishes, and even grass itself. Hence under the class of wines, or various liquors, come not only wines absolutely so called, but also ale, cyder, &c. See **BREWING**, and **CHEMISTRY**, p. 95, 161.

Wine in France is distinguished, from the several degrees and steps of its preparation, into, 1. *Mere goutte*, mother-drop, which is the virgin wine, or that which runs of itself out at the top of the vat wherein the grapes are laid, before the vintager enters to tread or stamp the grapes. 2. *Muſt*, furmull, or itum, which is the wine or liquor in the vat, after the grapes have been trod or stamped. 3. *Pressed wine*, being that squeezed with a press out of the grapes half bruised by the treading. The hulks left of the grapes are called rope, muck, or mark; by throwing water upon which and pressing them afresh, they make a liquor for servants use, answerable to our cyderkin, and called *boiffon*. 4. *Sweet wine*, is that which has not yet worked nor fermented. 5. *Bourru*, that which has been prevented working by casting in cold water. 6. *Worked wine*, that which has been let work in the vat, to give it a colour. 7. *Boiled wine*, that which has had a boiling before it worked, and which by that means still retains its native sweetness. 8. *Strained wine*, that made by steeping dry grapes in water, and letting it ferment of itself. Wines are also distinguished with regard to their colour into white wine, red wine, claret wine, pale wine, rose, or black wine; and with regard to their country, or the soil that produces them, into French wines, Spanish wines, Rhenish wines, Hungarian wines, Greek wines, Canary wines, &c. and more particularly

particularly into Port wine, Madeira wine, Burgundy wine, Champain wine, Falernian wine, Tockay wine, Schiras wine, &c.

Spirit of Wine. See CHEMISTRY, p. 163.

WING, that part of a bird, insect, &c. whereby it is enabled to fly. See NATURAL HISTORY.

WINGS, in heraldry, are borne sometimes single, sometimes in pairs; in which case, they are called conjoined. When the points are downward, they are said to be inverted; when up, elevated.

WINGS, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left sides thereof.

WINGS, in fortification, denote the longer sides of horn-works, crown-works, tenailles, and the like out-works; including the ramparts and parapets; with which they are bounded on the right and left, from their gorge to their front.

WINSLOW, a market-town of Bucks, six miles north of Aylesbury.

WINSTER, a market-town of Darbyshire, situated ten miles north of Darby.

WINTER, one of the four seasons or quarters of the year. See ASTRONOMY, p. 546.

WINTER'S BARK, in botany, a name given to the bark of the white or wild cinnamon tree. See CINNAMON.

WINTERTONNESSE, the north cape of the county of Norfolk, four miles north of Yarmouth.

WIRE, a piece of metal drawn through the hole of an iron into a thread of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine, as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire, are gold, silver, copper, and iron. Gold-wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller, till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is no where more conspicuous than in this gilt wire. A cylinder of forty-eight ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr. Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence ninety-eight yards of the wire weigh no more than forty-nine grains, and one single grain of gold covers the ninety-eight yards; so that the ten thousandth part of a grain is above one-eighth of an inch long.

WIRE of Lapland. The inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver-wire, and is therefore called, by those who do not examine its figure or substance, Lapland-wire. It is made of the sinews of the rein-deer, which being carefully separated in the eating, are, by the women, after soaking in water, and beating, spun into a sort of thread, of admirable fineness, and strength, when wrought to the smallest filaments: but when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads, covered with tin. The women do this business, and the way they take is to melt a piece of tin, and pla-

cing at the edge of it a horn with a hole through it, they draw these sinewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a small piece of bone placed at the top of the hole, where the wire is made flat, so that we always find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their cloaths as we do gold and silver; they often sell it to strangers, under the notion of its having certain magical virtues.

WIRKSWORTH, a market-town of Darbyshire, situated six miles north of Darby.

WISBEACH, a market-town of the isle of Ely, in Cambridgeshire, situated fifteen miles north of Ely.

WISDOM, usually denotes a higher and more refined notion of things immediately presented to the mind, as it were, by intuition, without the assistance of ratiocination.

WISTON, a market-town of Pembrokeshire, situated ten miles north of Pembroke.

WIT is a quality of certain thoughts and expressions: the term is never applied to an action nor to a passion, and as little to an external object.

However difficult it may be, in every particular instance, to distinguish a witty thought or expression from one that is not so; yet in general it may be laid down, that the term *wit* is appropriated to such thoughts and expressions as are ludicrous, and also occasion some degree of surprise by their singularity. Wit also, in a figurative sense, expresses that talent which some men have of inventing ludicrous thoughts or expressions: we say commonly, *a witty man*, or *a man of wit*.

Wit in its proper sense, as explained above, is distinguishable into two kinds; wit in the thought, and wit in the words or expression. Again, wit in the thought is of two kinds; ludicrous images, and ludicrous combinations of things that have little or no natural relation.

Ludicrous images that occasion surprise by their singularity, as having little or no foundation in nature, are fabricated by the imagination: and the imagination is well qualified for the office; being of all our faculties the most active and the least under restraint. Take the following example.

Shylock. You knew (none so well, none so well as you) of my daughter's flight.

Salino. That's certain; I, for my part, knew the tailor that made the wings she flew withal.

Merchant of Venice, act 3. sc. 1.

The image here is undoubtedly witty. It is ludicrous: and it must occasion surprise; for having no natural foundation, it is altogether unexpected.

The other branch of wit in the thought, is that only which is taken notice of by Addison, following Locke, who defines it "to lie in the assemblage of ideas; and putting those together, with quickness and variety, wherein can be found any resemblance or congruity, thereby to make up pleasant pictures and agreeable visions in the fancy." It may be defined more cutly, and perhaps more accurately, "a junction of things by distant and fanciful relations, which surprise because they are unexpected." The following is a proper example.

We grant although he had much wit,

He was very thy of using it,

9 B

†

As

As being loth to wear it out;
And therefore bore it not about,
Unless on holidays, or so,
As men their best apparel do.

Hudibras, canto 1.

Wit is of all the most elegant recreation: the image enters the mind with gaiety, and gives a sudden flash which is extremely pleasant. Wit thereby gently elevates without training, raises mirth without dissoluteness, and relaxes while it entertains.

Wit in the expression, commonly called a *play of words*, being a baltard sort of wit, is reserved for the last place. We proceed to examples of wit in the thought; and first of ludicrous images.

Falstaff, speaking of his taking Sir John Coleville of the Dale:

Here he is, and here I yield him; and I beseech your Grace, let it be book'd with the rest of this day's deeds; or, by the Lord, I will have it in a particular ballad else, with mine own picture on the top of it, Coleville killing my foot: to the which course if I be enforced, if you do not all shew like gilt twopences to me; and I, in the clear sky of fame, o'erhine you as much as the full moon doth the cinders of the elements, which shew like pins' heads to her; believe not the word of the noble. Therefore let me have right, and let desert mount.

Second Part, Henry IV act 4. sc. 6.

I knew, when seven justices could not take up a quarrel but when the parties were met themselves, one of them thought but of an *if*; as, if you had said so, then I said so; and they shook hands, and swore brothers. Your *if* is the only peace-maker; much virtue is in *if*.

Shakespeare.

For there is not through all nature another so callous and insensible a member as the world's posteriors, whether you apply to it the toe or the birch.

Preface to a Tale of a Tub.

The other branch of wit in the thought, *viz.* ludicrous combinations and oppositions, may be traced through various ramifications. And, first, fanciful causes assigned that have no natural relation to the effects produced:

Lancaster. Fare you well, Falstaff; I, in my condition, shall better speak of you than you deserve. *[Exit.]*

Falstaff. I would you had but the wit; 'twere better than your dukedom. Good faith, this same young foer-blooded boy doth not love me; nor a man cannot make him laugh; but that's no marvel, he drinks no wine. There's never any of these demure boys come to any proof; for thin drink doth so overcool their blood, and making many fish-meals, that they fall into a kind of male green-sickness; and then, when they marry, they get wenches. They are generally fools and cowards; which some of us should be too, but for inflammation. A good sherris-sack hath a twofold operation in it: it ascends me into the brain; dries me there all the foolish, dull, and crudy vapours which environ it; make it apprehensive, quick, forgetive, full of nimble, fiery, and delectable shapes; which delivered o'er to the voice, the tongue, which is the birth, becomes excellent wit. The second property of your excellent sherris is, the warming of the blood; which before cold and settled, left the liver white and pale; which is the badge of pusillanimity

and cowardice: but the sherris warms it, and makes it course from the inwards to the parts extreme; it illuminates the face, which, as a beacon, gives warning to all the rest of this little kingdom, man, to arm; and then the vital commoners and inland petty spirits muster me all to their captain, the heart; who, great, and puff'd up with this retinue, doth any deed of courage; and thus valour comes of sherris. So that skill in the weapon is nothing without sack, for that sets it a-work; and learning a mere hoard of gold kept by a devil, till sack commences it, and sets it in act and use. Hereof comes it that Prince Harry is valiant; for the cold blood he did naturally inherit of his father, he hath, like lean, sterile, and bare land, manured, husbanded, and till'd with excellent endeavour of drinking good and good store of fertile sherris, that he is become very hot and valiant. If I had a thousand sons, the first human principle I would teach them, should be to forswear thin potations, and to addict themselves to sack.

Second Part of Henry IV. act 4. sc. 7.

The trenchant blade, toledo trusty,
For want of fighting was grown rusty,
And ate into itself, for lack
Of some body to hew and hack.
The peaceful scabbard where it dwelt
The rancor of its edge had felt:
For of the lower end two handful
It had devoured, 'twas so manifold;
And so much scorn'd to lurk in case,
As if it durst not shew its face.

Hudibras, canto 1.

To account for effects by such fantastical causes, being highly ludicrous, is quite improper in any serious composition. Therefore the following passage from Cowley, in his poem on the death of Sir Henry Wootton, is in a bad taste.

He did the utmost bounds of knowledge find,
He found them not so large as was his mind.
But, like the brave Pellean youth, did moan,
Because that art had no more worlds than one.
And when he saw that he through all had past,
He dy'd, lest he should idle grow at last.

Fanciful reasoning:

Falstaff. Imbowell'd!—if thou imbowel me to day, I'll give you leave to powder me, and eat me to-morrow! S'blood, 'twas time to counterfeit, or that hot terma-gant Scot had paid me scot and lot too. Counterfeit? I lie, I am no counterfeit: to die is to be a counterfeit; for he is but the counterfeit of a man, who hath not the life of a man; but to counterfeit dying, when a man thereby liveth, is to be no counterfeit, but the true and perfect image of life indeed.

First Part Henry IV. act 1. sc. 10.

Clown. And the more pity that great folk should have countenance in this world to drown or hang themselves, more than their even Christians.

Hamlet, act 5. sc. 2.

Pedro. Will you have me, Lady?

Beatrice. No, my Lord, unless I might have another for working days. Your Grace is too costly to wear every day.

Much ado about nothing, Act 2. sc. 5.

Jesse.

Jessica. I shall be saved by my husband; he hath made me a Christian.

Launcelot. Truly the more to blame he; we were Christians enough be ore, e'en as many as could well live by one another: this making of Christians will raise the price of hogs; if we grow all to be pork eaters, we shall not have a rather on the coals for money.

Merchant of Venice, Act 3. sc. 6.

But Hudibras gave him a twitch,
As quick as lightning, in the breech,
Just in the place where honour's lodg'd,
As wise philosophers have judg'd;
Because a kick in that part, more
Hurts honour, than deep wounds before.

Hudibras, canto 3.

Ludicrous junction of small things with great, as of equal importance:

This day black omens threat the brightest fair
That e'er deferr'd a watchful spirit's care:
Some dire disaster, or by force, or flight:
But what, or where, the fates have wrapt in night:
Whether the nymph shall break Diana's law;
Or some frail china jar receive a flaw:
Or stain her honour, or her new brocade;
Forget her pray'rs, or miss a masquerade;
Or lose her heart, or necklace, at a ball;
Or whether Heav'n has doom'd that Shock must fall.

Rape of the Lock, canto ii. 101.

Or speaks the glory of the British Queen,
And one describes a charming Indian Green.

Ibid. canto iii. 13

Then flash'd the living lightning from her eyes,
And screams of horror rend th'affrighted skies.
Nor louder shrieks to pitying heav'n are cast,
When husbands, or when lapdogs, breathe their last;
Or when rich china vessels fall'n from high,
In glittering dust and painted fragments lie!

Ibid. canto iii. 155.

Not youthful kings in battle seiz'd alive,
Not scornful virgins who their charms survive,
Not ardent lovers robb'd of all their bliss,
Not ancient ladies when refus'd a kiss,
Nor tyrants fierce that unrepenting die,
Nor Cynthia when her manteau's pinn'd awry,
E'er felt such rage, resentment, and despair,
As thou, sad virgin! for thy ravish'd hair.

Ibid. canto iv. 3.

Joining things that in appearance are opposite. As for example, where Sir Roger de Coverley, in the spectator, speaking of his widow,

That he would have given her a coal-pit to have kept her in clean linen; and that her woe should have sparkled with one hundred of his richest acres.

Premises that promise much and perform nothing. Cicero upon this article says,

Sed scitis esse notissimum ridiculum genus, cum aliud expectamus, aliud dicitur: hic nobilissimisque noster error risum movet.

Decoratore, l. 2 c 63.

Beatrice.—With a good leg and a good foot, uncle, and money enough in his purse, such a man would win any

woman in the world, if he could get her good will.

Much ado about nothing, Act. 2. sc. 1.

Beatrice. I have a good eye, uncle, I can see a church by day light.

Having discussed wit in the thought, we proceed to what is verbal only, commonly called a *play of words*. This sort of wit depends, for the most part, upon chusing a word that hath different significations: by this artifice, hocus-pocus tricks are played in language; and thoughts plain and simple take on a very different appearance. Play is necessary for man, in order to refresh him after labour; and accordingly man loves play: he even relishes a play of words: and it is happy for us, that words can be employed, not only for useful purposes, but also for our amusement. This amusement accordingly, though humble and low, is relished by some at all times, and by all at some times, in order to unbind the mind.

It is remarkable, that this low species of wit, has, at one time or other, made a figure in most civilized nations, and has gradually gone into disrepute. So soon as a language is formed into a system, and the meaning of words is ascertained with tolerable accuracy, opportunity is afforded for expressions, which, by the double meaning of some words, give a familiar thought the appearance of being new; and the penetration of the reader or hearer is gratified, in detecting the true sense disguised under the double meaning. That this sort of wit was in England deemed a reputable amusement, during the reigns of Elizabeth and James I is vouched by the works of Shakespear, and even by the writings of grave divines. But it cannot have any long endurance: for as language ripens, and the meaning of words is more and more ascertained, words held to be synonymous diminish daily; and when those that remain have been more than once employed, the pleasure vanisheth with the novelty.

We proceed to examples, which, as in the former case, shall be distributed into different classes.

A seeming resemblance from the double meaning of a word:

Beneath this stone my wife doth lie;
She's now at rest, and so am I.

A seeming contrast from the same cause, termed a *verbal antithesis*, which hath no despicable effect in ludicrous subjects:

Whilst Iris his cosmetic wash would try
To make her bloom revive, and lovers die.
Some ask for charms, and others philters chuse,
To gain Corinna, and their quarters lose.

Dispensary, canto 2;

And how frail nymphs, oft, by abortion, aim
To lose a substance, to preserve a name.

Ibid. canto 3;

While nymphs take treats, or assignations give.

Rape of the Lock,

Other seeming connections from the same cause:

Will you employ your conqu'ring sword,
To break a fiddle and your word?

Hudibras, canto 2.

To whom the knight with comely grace
Put off his hat to put his case.

Hudibras, part 3. canto 3:

Here

Here Britain's statesmen oft the fall foredoom
Of foreign tyrants, and of nymphs at home ;
Here thou, great Anna ! whom three realms obey,
Dost sometimes counsel take—and sometimes tea.

Rape of the Lock, canto 3. l. 5.

O'er their quietus where fat judges dose,
And lull their cough and conscience to repose.

Dispensary, canto 1.

Speaking of Prince Eugene :

This general is a great taker of snuff as well as of
towns.

Pope, Key to the Lock,

Exul mentisque domusque.

Metamorphoses, lib. ix. 409.

A seeming opposition from the same cause :

Hic quiescit qui nunquam quievit.

Again,

So like the chances are of love and war,
That they alone in this distinguish'd are ;
In love the victors from the vanquish'd fly,
They fly that wound, and they pursue that die.

Waller.

What new-found witchcraft was in thee,
With thine own cold to kindle me ?
Strange art ; like him that should devise
To make a burning glass of ice.

Cowley.

Wit of this kind is unsuitable in a serious poem ; witness
the following line in Pope's Elegy to the memory of an
unfortunate lady :

Cold is that breath which warm'd the world before.

This sort of writing is finely burlesqued by Swift :

Her hands, the softest ever felt,
Though cold would burn, though dry would melt.

Strephon and Chloe.

Taking a word in a different sense from what is meant,
comes under wit, because it occasions some slight degree of
surprise :

Beatrice. I may sit in a corner, and cry *Heigh ho!* for
a husband.

Pedro. Lady Beatrice, I will get you one.

Beatrice. I would rather have one of your father's get-
ting. Hath your Grace ne'er a brother like you ? Your
father got excellent husbands, if a maid could come by
them.

Much ado about nothing, act 2. sc. 5.

Falstaff. My honest lads, I will tell you what I am
about.

Pistol. Two yards and more.

Falstaff. No quips now, Pistol : indeed, I am in the
waite two yards about : but I am now about no waste ; I
am about thrift.

Merry Wives of Windsor, act 1. sc. 7.

Lo. Sands.—By your leave, sweet ladies,
If I chance to talk a little wild, forgive me :

I had it from my father.

Anne bullen. Was he mad, Sir ?

Sands. O, very mad, exceeding mad, in love too ;
But he would bite none—

K. Henry VIII.

An assertion that bears a double meaning, one right, one
wrong, but so connected with other matters as to direct
us to the wrong meaning, is a species of bastard wit which
is distinguished from all others by the name *pun*. For ex-
ample,

Paris.—Sweet Helen, I must woo you
To help unarm our Hector : his stubborn armour,
With these your white enchanting fingers touch'd,
Shall more obey, than to the edge of steel,
Or force of Greekish sinews ; you shall do more
Than all the island kings, disarm great Hector.

Troilus and Cressida, act 3. sc. 2.

The pun is in the close. The word *disarm* has a double
meaning : it signifies to take off a man's armour, and also
to subdue him in fight. We are directed to the latter sense
by the context ; but with regard to Helen, the word
holds only true in the former sense. We go on with other
examples :

Esse nihil dicis quicquid petis, improbe Cinna :

Si nil, Cinna, petis, nil tibi, Cinna, nego.

Martial, l. 3. epigr. 61.

Chief Justice. Well ! the truth is, Sir John, you live
in great infamy.

Falstaff. He that buckles him in my belt cannot live in
less.

Chief Justice. Your means are very slender, and your
waite is great.

Falstaff. I would it were otherwise : I would my means
were greater, and my waite slenderer.

Second part Henry IV. act 1. sc. 5.

Celia. I pray you bear with me, I can go no further.

Clown. For my part, I had rather bear with you than
bear you : yet I should bear no cross if I did bear you ;
for I think you have no money in your purse.

As you like it, act 2. sc. 4.

He that imposes an oath makes it,

Not he that for convenience takes it.

Then how can any man be said

To break an oath he never made ?

Rudibras, part 2. canto 2.

The seventh satire of the first book of Horace is purposely
contrived to introduce at the close a most execrable pun.
Talking of some infamous wretch whose name was *Rex Ru-*
pilius,

Perlius exclamat, Per magnos, Brute, deos te

Oro, qui reges confueris tollere, cur non

Hunc regem jugulas ? Operum hoc, mihi crede, tuorum
est.

Though playing with words is a mark of a mind at ease,
and disposed to any sort of amusement we must not thence
conclude that playing with words is always ludicrous.
Words are so intimately connected with thought, that if
the subject be really grave, it will not appear ludicrous even
in this fantastic dress. We are, however, far from recom-
mending it in any serious performance : on the contrary,
the discordance between the thought and expression must
be disagreeable ; witness the following specimen.

He

He hath abandoned his physicians. Madam, under whose practices he hath perfected time with hope; and finds no other advantage in the process, but only the losing of hope by time.

All's well that ends well, act 1. sc. 1.

K. Henry. O my poor kingdom, sick with civil blows! When that my care could not with-hold thy riots, What wilt thou do when riot is thy care?

Second part K Henry IV.

If any one shall observe, that there is a third species of wit, different from those mention'd, consisting in sounds merely. we are willing to give it place. And indeed it must be admitted, that many of Hudibras's double rhymes come under the definition of wit given in the beginning of this article: they are ludicrous, and their singularity occasions some degree of surprize. Swift is not less successful than Butler in this sort of wit; witness the following instances: *Goddest—Boddice. Pliny—Nicolini. Jscariots—Charists. Mitre—Nitre. Dragon—Suf-fragan.*

A repartee may happen to be witty: but it cannot be considered as a species of wit; because there are many repartees extremely smart, and withal extremely serious. We give the following example. A certain petulant Greek, objecting to Anacharis that he was a Scythian: True, says Anacharis, my country disgraces me, but you disgrace your country. This fine turn gives surprize; but it is far from being ludicrous.

WITCHCRAFT, a kind of sorcery, especially in women, in which it is ridiculously supposed that an old woman, by entering into a contract with the devil, is enabled, in many instances, to change the course of nature; to raise winds; to perform actions that require more than human strength; and to afflict those who offend them with the sharpest pains, &c. In the times of ignorance and superstition, many severe laws were made against witches, by which great numbers of innocent persons, distressed with poverty and age, were brought to a violent death; but these are now happily repealed. See *LAW Tit. xxxiii 8.*

WITENA MOT, or **WITENA GEMOT**, among our Saxon ancestors, was a term which literally signified the assembly of the wise men, and was applied to the great council of the nation, of latter days called the parliament.

WITEPSKI, the capital of the palatinate of the same name, in the duchy of Lithuania, in Poland: E. long 30°, N. lat 56°

WITCHAM, a market-town of Essex, ten miles north-east of Chelmsford.

WITHERS of a horse, the juncture of the shoulder-bones at the bottom of the neck and main, towards the upper part of the shoulder.

WITNESS, in law, a person who gives evidence in any cause, and is sworn to speak the truth the whole truth, and nothing but the truth. See *LAW Tit. xxi. 4. &c.* and *Tit. xxxi 1, &c.*

WITNEY, a market-town of Oxfordshire. seven miles west of Oxford. Here is the greatest manufacture of blankets in England.

WITTENBURG, a city of Germany, in the circle of Upper Saxony, fifty miles north of Dresden.

WITTLESEYMERE, a lake in the isle of Ely, on the confines of Huntingdonshire, six miles long and three broad.

WIVELSCOMB, a market-town of Somersetshire, situated twenty seven miles south-west of Wills.

WOAD, in botany. See *ISATIS*.

WOBURN, a market-town of Bedfordshire, ten miles south of Bedford.

WOLAW, the capital of a duchy of the same name, in Bohemia: E. long. 16° 38'. N. lat. 51° 22'.

WOLF in zoology. See *CANIS*.

WOLFENBUTTEL, a city of Germany, in the circle of lower Saxony, and duchy of Brunwick: E. long. 10° 32'. N. lat. 52° 20'.

WOLFERDYKE, an island of the united Netherlands, in the province of Zealand, situated between the islands of north Beveland and south Beveland.

WOLGA, a large river of Russia, which rising in the north of that empire, runs south-east till it falls into the Caspian sea, about fifty miles below Astracan, after its having run a course of between two and three thousand miles.

WOLGAST, a city and port-town of Germany, in the circle of Upper Saxony, and duchy of Pomerania, subject to Sweden: E. long. 14° 5'. N. lat. 54° 12'.

WOLKOWSKA, a city of Poland, in the duchy of Lithuania, and palatinate of Novogrodeck: E. long. 24°, N. lat. 53°.

WOLLIN, a town and island of Pomerania, situated in the Baltic sea, at the mouth of the river Oder, subject to the king of Prussia.

WOLODOMIR the capital of a province of the same name in Russia: E. long. 30° 5'. N. lat. 57° 40'.

WOLOGDA, the capital of a province of the same name in Russia, situated on the river Dwina: E. long. 42° 20', N. lat. 59°.

WOLVERHAMPTON, a market-town of Staffordshire, eleven miles south of Stafford.

WOLVES-TEETH, of an horse, are over-grown grinders, the points of which being higher than the rest, prick his tongue and gums in feeding, so as to hinder his chewing. They are seldom met with in any besides young horses; but if they be not daily worn by chewing, they will grow up even to pierce the roof of the mouth.

WOMAN, the female of man. See *HOMO*.

WOMB. See *ANATOMY. p. 274.*

WOOD, a solid substance, whereof the trunks and branches of trees consist.

The wood is all that part of a tree included between the bark and the pith. For the structure of the pith, bark, wood, &c. of plants, see *AGRICULTURE. p. 40.*

WOODBRIDGE, a market-town of Suffolk, situated twenty-six miles south-east of Bury.

WOOD COCK, in ornithology. See *SCOLOPAX*.

WOOD LOUSE, in zoology. See *ONISCUS*.

WOOD PECKER, in ornithology. See *PICUS*.

WOODSTOCK, a borough-town of Oxfordshire, situated seven miles north of Oxford. It sends two members to parliament.

WOOF, among manufacturers, the threads which the weavers shut across with an instrument called the shuttle. See *CLOTH*.

WOOL, the covering of sheep. See *OVIS*.

WOOLWICH, a market-town of Kent, situated on the river Thames, six miles east of London.

WORCESTER, the capital city of worcestershire, situated

- ted on the river Severn, 110 miles north-west of London: W. long. $2^{\circ} 15'$, N. lat. $52^{\circ} 5'$.
- WORCUM**, a town of Holland, situated on the river Waal, twenty-three miles east of Rotterdam. This is also the name of a port-town of the United Netherlands, situated on the province of Friesland, on the Zuyder-sea, twenty miles south-west of Lewarden.
- WORD**, in language, an articulate sound designed to represent some idea. See **GRAMMAR** and **LANGUAGE**.
- WORKSOP**, a market-town of Nottinghamshire, situated twenty miles north of Nottingham.
- WORLD**, the assemblage of parts which compose the globe of the earth. See **GEOGRAPHY**, and **ASTRONOMY**.
- WORMS**. See **NATURAL HISTORY**.
- WORMS**, in medicine. See **MEDICINE**, p. 160.
- Earth-WORM**. See **LUMBRICUS**.
- WORM**, in gunnery, a screw of iron, to be fixed on the end of a rammer, to pull out the wad of a firelock, carbine, or pistol, being the same with the wad-hook, only the one is more proper for small arms, and the other for cannon.
- WORM**, in chemistry, is a long, winding, pewter pipe, placed in a tub of water, to cool and condense the vapours in the distillation of spirits.
- WORMS**, in geography, an imperial city of Germany, in the palatinate of the Rhine: E. long. $8^{\circ} 5'$, N. lat. $49^{\circ} 38'$.
- WORMWOOD**, in botany. See **ARTEMISIA**.
- WORSTED**, a kind of woolen thread, which, in the spinning, is twisted harder than ordinary. It is chiefly used either wove or knit into stockings, caps, gloves, or the like.
- WORSTED**, a market-town of Norfolk, situated seven miles north of Norwich.
- WOTTON**, a market town of Gloucestershire, situated seventeen miles south of Gloucester.
- WOTTON BASSET**, a borough-town of Wiltshire, twenty-five miles north of Salisbury; which sends two members to parliament.
- WOUND**, in surgery. See **SURGERY**, p. 643.
- WRASSE**, or **OLD WIFE**, in ichthyology. See **LABRUS**.
- WREATH**, in heraldry, a roll of fine linen or silk (like that of a Turkish turbant) consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest.
- WREN**, in ornithology. See **MORACILLA**.
- WRESTLING**, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground. See **GAMES**, &c.
- WREXHAM**, a market-town of Denbighshire, in Wales, situated twenty-three miles south-east of St. Asaph.
- WRINTON**, a market-town of Somersetshire, situated seven miles north of Wells.
- WRIST**, in anatomy. See **ANATOMY**, p. 179.
- WRIT**, in law, signifies, in general, the king's precept in writing under seal, issuing out of some court, directed to the sheriff, or other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done.
- WRITING**, the art or act of signifying and conveying our ideas to others, by letters, or characters, visible to the eye. See **COMPOSITION**, **GRAMMAR**, and **LANGUAGE**.
- WRONG**, in a logical sense. See **ERROR**, **FALSEHOOD**, **TRUTH**, &c.
- WRONG** in a legal sense, the same with injury, or tort.
- WRONGOUS Imprisonment**, in Scots law. See **LAW**, Tit. XXXIII. 23.
- WURTEMBERG** in Germany, is the north part of the circle of Swabia.
- WURZBURG**, a city of Germany in the circle of Franconia, capital of the bishopric of that name, situated on the river Main: in E. long. $9^{\circ} 50'$, N. lat. $49^{\circ} 46'$.
- WYE**, a market-town of Kent, situated twenty miles south-east of Maidstone.
- WYE** is also a river of Wales, which, rising on the confines of Cardiganhire, and running south-east, divides the counties of Radnor and Brecknock: then crossing Herefordshire it turns south, and falls into the mouth of the Severn at Chepstow.

X.

X A N

- XACA**, a port-town of Sicily in the province of Mazara, forty miles south of Palermo: E. long. 13° , N. lat. 37° .
- XALISCO**, a city of Mexico, in America, situated near the Pacific ocean, four hundred miles west of the capital city of Mexico: W. long. 120° , and N. lat. $22^{\circ} 20'$.
- XANSI**, a province of China, bounded by the province of Peking on the east, by the great wall on the north, by the province of Honan on the south, and by the river Croci, which divides it from the province of Xensi, on the west.
- XANTHIUM**, in botany, a genus of the monœcia pentandria class. The common calix of the male is imbricated;

X A V

- the corolla is funnel shaped, and divided into five segments; and the receptacle is paleaceous: The calix of the female consists of two leaves, including two flowers; it has no corolla: the drupa is dry, muricated, and divided into two segments; and the nucleus has two cells. There are three species, only one of them, viz. the strumarium, or lesser burdock, a native of Britain.
- XANTIUM**, a province of China, in Asia, bounded by the Kang sea on the north, by the gulf of Nankin on the east, by the province of Nankin on the south, and by the province of Peking on the west.
- St. XAVIER**, a town of the province of La Plata, or Guayra, in South America, situated on the confines of Brazil,

fil, two hundred miles west of Rio Janeiro: W. long. 50°, S. lat. 24°.

XENSI, a province of China, bounded by the great wall on the north, by the province of Xanfi on the east, by the province of Suchuen on the south, and by Tibet on the west.

XERANTHEMUM, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is paleaceous; the pappus is fetaceous; and the calix is imbricated, and radiated. There are eleven species, none of them natives of Britain.

XEROPHAGIA, in church-history, the eating of dried foods: so the ancient Christians called certain fast days, on which they eat nothing but bread and salt, and drank only water: sometimes they added pulse, herbs, and fruits. This sort of fasting was observed chiefly in the holy-week, out of devotion, and not by obligation.

XICHU, a city of China, in the province of Huguan: E. long. 112°, N. lat. 27°.

XINYAN, a city of Asia, in the province of Laotung: E. long. 120°, N. lat. 31°.

XIPHIAS, in ichthyology, a genus belonging to the order of apodes. The upper jaw terminates in a long sword-shaped rostrum: from which it is called the sword-fish: there are no teeth in the mouth; the gill-membrane has eight rays; and the body is somewhat cylindrical. There is but one species, found in the European ocean.

XIPHOIDES, in anatomy. See ANATOMY, p. 175.

XYLO-ALOES, or **ALOE-WOOD**, in pharmacy. See ALOE.

This drug is distinguished into three sorts, the calambac, the common lignum aloes, and calambour.

The calambac, or finest aloes-wood, called by authors lignum aloes præstantissimum, and by the Chinese luk-hiang, is the most refinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth, in the manner of mastic. This kind, laid on the fire, melts in great parts like resin, and burns away in a few moments, with a bright flame and perfumed smell. Its scent, while in the mass, is very fragrant and agreeable: and its taste acrid and bitterish, but very aromatic and agreeable: it is so variable in its colour, that some have divided it into three kinds, the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone, like the yolk of an egg: this last is the least scented of the three: the substance however, in them all, is the same in every respect, except their colour. It is brought from Cochinchina.

The lignum aloes vulgare is the second in value. This is of a more dense and compact texture, and consequently less refinous than the other; there is some of it, however, that is spongy, and has the holes filled up with the right refinous matter; and all of it, when good, has veins of the same resin in it. We meet with it in small fragments, which have been cut and split from larger; these are of a tolerably dense texture in the more solid pieces, and of a dusky brown colour, variegated with refinous black veins. It is in this state very heavy, and less fragrant than in those pieces which shew a multitude

of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish or even blackish. The smell of the common aloes-wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very aromatic. This wood is also brought from Cochinchina, and sometimes from Sumatra.

The calambour, or, as some write it, calambouc, is also called agallochum sylvestre, and lignum aloes mexicanum. It is a light and friable wood, of a dusky and often mottled colour, between a dusky green black, and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. We meet with this very frequent, and in large logs; and these sometimes entire, sometimes only the heart of the tree, the cortical part being separated. This is brought from the island of Timor, and is the aloes-wood used by the cabinet-makers and playfers.

The Indians use the calambac by way of incense, burning small pieces of it in the temples of their gods; and sometimes their great people burn it in their houses, in times of fasting. It is esteemed a cordial, taken inwardly; and they sometimes give it in disorders of the stomach and bowels, and to destroy worms. A very fragrant oil may be procured from it, by distillation; which is recommended in paralytic cases, from five to fifteen drops. It is at present, however, but little used; and would scarce be met with any where in the shops, but that it is an ingredient in some of the old compositions.

XYLO-BALSAMUM, a name which naturalists give to the wood of the tree which yields that precious gum known to the Latins by the name of opobalsamum, and to us by the balm of Gilead. See BALSAM.

We have branches of this tree brought us from Cairo: they are very strait, brittle, unequal, and full of knots; their bark reddish without, and greenish within. The xylo-balsamum is reputed good to strengthen the brain and stomach, and to expel poison.

XYLOCASIA, in the materia medica, the same with the cassia ligna. See CASSIA.

XYLON, the PRICKLY COTTON TREE, in botany, a genus of the polyandria monogynia class of plants, the corolla whereof consists of a single petal, divided into five oval, hollow, patent segments; the fruit is a large, oblong, turbinate capsule, formed of five woody valves, and containing five cells; the seeds are roundish, and fixed to a columnar pentagonal receptacle, and have a quantity of fine down, or cotton, adhering to them.

XYNOECIA, in Grecian antiquity, an anniversary feast, observed by the Athenians, in honour of Minerva, upon the sixteenth of Elecatombeon, in memory that, by the persuasion of Theseus, they left their country seats, in which they lay dispersed here and there in Attica, and united together in one body.

XYRIS, in botany, a genus of the triandria monogynia class. The corolla consists of three equal crepated petals; and the gluma consists of two valves. There is but one species, a native of India.

XYSTARCHA, in antiquity, the master or director of the xyllus. In the Greek gymnasium, the xystarcha was the second

second officer, and the gymnasiarcha the first; the former was his lieutenant, and presided over the two xylti, and all exercitiks of the athletæ therein.

XYSTUS, among the Greeks, was a long portico, open or covered at the top, where the athletæ practised wrestling

and running: the gladiators, who practised therein, were called xyltici.

Among the Romans, the xystus was only an alley, or double row of trees, meeting like an arbour, and forming a shade to walk under.

Y.

Y A W

Y E O

YACHT, or **YATCH**, a vessel with one deck, carrying from four to twelve guns. See **SHIP**.

YARD, a measure of length used in Britain and Spain, consisting of three feet, chiefly to measure cloth, stuffs, &c.

YARD in anatomy See **ANATOMY** p. 270.

YARDS of a *ship*. are those long pieces of timber which are made a little tapering at each end, and are fitted athwart its proper mast, with the sails made fast to them. so as to be hoisted up, or lowered down, as occasion serves. They have their names from the masts unto which they belong.

YARD-ARM is that half of the yard that is on either side of the mast, when it lies athwart the ship

YARDS also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. There are, belonging to his majesty's navy, six great yards, *viz.* Chatham, Deptford, Woolwich, Portsmouth, Sheerness, and Plymouth: these yards are fitted with several docks, wharfs, lanches, and graving places for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores needful for the royal navy.

YARE, among sailors, implies ready or quick: as, be yare at the helm; that is, be quick, ready, and expeditious at the helm. It is sometimes also used for bright by seamen: as, to keep his arms yare; that is, to keep them clean and bright.

YARE, a river of Norfolk. which runs from west to east, through that country, passing by Norwich, and falling into the German sea at Yarmouth.

YARMOUTH, a borough and port town of Norfolk, situated on the German sea, at the mouth of the river Yare, twenty miles east of Norwich. It sends two members to parliament.

YARMOUTH is also a borough-town of the Isle of Wight, in Hampshire, situated on the north-west coast of the Island, six miles west of Newport. It sends two members to parliament.

YARN, wool or flax spun into thread, of which they weave cloth. See **CLOTH**.

YARUM, a market-town of the north riding of Yorkshire situated on the river Tees, thirty miles north of York

YAWNING, an involuntary opening of the mouth, occa-

sioned by a vapour or ventosity endeavouring to escape, and generally witnessing an irksome weariness, or an inclination to sleep. Yawning according to Boerhaave, is performed by expanding at one and the same time all the muscles capable of spontaneous motion; by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air; and gradually and slowly breathing it out, after it has been retained for some time, and satisfied; and then restoring the muscles to their natural state. Hence the effect of yawning is to move, accelerate, and equally distribute all the humours through all the vessels of the body, and consequently to qualify the muscles and organs of sensation for their various functions.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To those a person is most inclined just after sleep, because, a greater quantity going off by the pores of the skin than at other times, whensoever a person wakes, the increased contraction that then happens eludes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contacts of their fibres, and the inclosed matter, by degrees throw it off. Hence we see the reason why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto.

YAWS, in the sea language. A ship is said to make yaws, when she does not steer steady, but goes in and out when there is a stiff gale.

YAWS, a distemper endemial to Guinea and the hotter climates in Africa. See **MEDICINE**, p. 137.

YEAR. See **ASTRONOMY**, p. 489

YEAR and **Day** in S.o.s law. See **LAW**, Tit. vi. 21, 22.

YELLOW, one of the original colours of light.

YELLOWs, a disease in a horse, much the same with that called the jundice in man. See **FARRIERY** p. 561.

YELLOW-HAMMER, in ornithology. See **FRINGILLA**.

YEOMAN, the first or highest degree among the plebeians of England, next in order to the gent. y.

The Yeomen are properly freeholders, who having land of their own, live on good husbandry.

YEOMAN is also a title of office in the king's household, of a middle place or rank between an usher and a groom.

YEOMAN

YEOMEN of the guard were anciently two hundred and fifty men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high.

At present there are but one hundred yeomen in constant duty, and seventy more not in duty; and as any of the hundred dies, his place is supplied out of the seventy.

They go dressed after the manner of king Henry VIII's time. They formerly had diet as well as wages when in waiting, but this was taken off in the reign of queen Anne.

YEOVIL, a market-town of Somersetshire, situated eighteen miles south of Wells.

YEST, a head or scum rising upon beer or ale, while working or fermenting in the vat. See **BREWING**.

It is used for a leaven or ferment in the baking of bread, as serving to swell or puff it up very considerably in a little time, and to make it much lighter, softer, and more delicate.

YEW, in botany. See **TAXUS**.

YLA, one of the western islands of Scotland, situated in the Irish-sea, west of Cantire.

YNCA, an appellation anciently given to the kings of Peru, and the princes of their blood; the word literally signifying lord, king, emperor, and royal blood.

YOAK, or **YOKK**, in agriculture, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

YOAK of land in our ancient customs, was the space which a yoke of oxen, that is, two oxen, may plow in one day.

Sea YOAK. When the sea is so rough that the helm can not be governed by the hands, the seamen make a yolk to steer by; that is, they fix two blocks to the end of the helm, and reeving two small ropes through them,

which they call falls, by having some men at each tackle, they govern the helm by direction. They have another way of making a sea yolk, by taking a double turn about the end of the helm with a single rope, the ends being laid to the ship's sides, by means whereof they guide the helm.

YOANGFU, a city of China, in the province of Hugnam, situated on the river Kiam E. long. 114°. N. lat. 20° 40'.

YOLK, the yellow part in the middle of an egg. See **EGG**.

YONNE, a river in France, which rising in Burgundy, and running north through Nivernois and Champaing, falls into the Seine at Montereau fur Yonne.

YORK, the capital city of Yorkshire, situated on the river Oule, 180 miles north of London: W. long. 50', N. lat. 54°. It is a large city, and has some good buildings in it, particularly the cathedral, which is a Gothic pile, equal to any thing of the kind in England. It is the see of an archbishop, and sends two members to parliament.

NEW YORK, one of the British colonies in North America, which comprehending the Jerseys, that frequently have the same governor, is situated between 72° and 74° of W. long. and between 41° and 44° of N. lat. bounded by Canada on the north, New England on the east, the American Sea on the south, and Pensilvania and the country of the Iroquois on the west.

NEW YORK, the capital city of this province, is situated on an island in the mouth of Hudson's river, in W. lon. 72° 30'. N. lat. 41°.

YUCCA, in botany, a genus of the hexandria monogynia class. The corolla is open and bell-shaped; it has no stylus, and the capsule has three cells. There are four species, all natives of America.

A kind of bread is made from the dried root of this plant by the Indians, which much resembles that made from the root of the cassida or scutellaria of Linnæus.

Z.

Z A M

ZAARA, one of the divisions of Africa, situated under the tropic of cancer, is bounded by Bildulgerid on the north, by the unknown parts of Africa on the east, by Nigritia or Negroland on the south, and by the Atlantic ocean on the west. This is a barren desert, and so destitute of water, that the camels which pass over it from Morocco to traffic with Negroland, are half loaded with water and provisions.

ZAFFER, or **ZAFRE**, in chemistry, the name of a blue substance, of the hardness and form of a stone; and generally supposed to be a native fossil.

It is in reality, however, a preparation of cobalt; the calx of that mineral being mixed with powdered flints and wetted with water to bring it into this form.

ZAMORA, a city of Spain, in the province of Leon, situated on the river Douro, thirty-two miles north of Salamanca: W. long. 6°. N. lat. 41° 30'.

Vol. III. N°. 100.

Z A N

ZANGUEBAR. a country on the east coast of Africa, situated in southern latitude between the equator and the tropic of capricorn, being bounded by the country of Anian on the north, by the Indian ocean on the west, by Caffraria on the south, and by the unknown parts of Africa on the west.

ZANNICHELLIA in botany, a genus of the monœcia monandria class. The male has neither calix nor corolla. The calix of the female consists of one leaf; it has no corolla; and there are four germina, and as many seeds. There is but one species, viz the palustris, or horned pond weed, a native of Britain.

ZANONIA, in botany, a genus of the diœcia pentandria class. The calix of both male and female consists of three leaves, and the corolla of five segments; the female has three styli; and the berry contains two seeds. There is but one species, a native of Malabar.

ZANTE, an island in the Mediterranean sea, situated E. long. $21^{\circ} 30'$, N. lat. $37^{\circ} 50'$, being about twenty four miles long, and twelve broad. The chief town is Zant, and is situated on the east side of the island, being well fortified and defended by a castle.

ZAPATA, a kind of feast or ceremony held in Italy, in the courts of certain princes, on St Nicholas's day; wherein people hide presents in the shoes or slippers of those they would do honour to, in such a manner as may surprise them on the morrow when they come to dress; being done in imitation of the practice of St Nicholas, who used in the night-time to throw purses of money in at the windows, to marry poor maids withal.

ZARA, a city of Dalmatia, situated on the gulph of Venice: E. long. 17° , N. lat. 44° .

ZARNAW, a city of Poland, in the province of Little Poland and palatinate of Sandomir, situated E. long. 20° , N. lat. $51^{\circ} 30'$.

ZEa, **INDIAN CORN**, in botany, a genus of the monoclea triandria class. The calix of the male is a double flowered glume, without any awn; the corolla is likewise a glume, without any awn; the calix and corolla of the male consists each of two valves; the stylus is filiform, and pendulous; and the seeds are solitary, being sunk in an oblong receptacle. There is but one species, a native of America.

ZEAL, the exercise of a warm animated affection, or passion, for any thing.

ZEALAND, the chief of the Danish islands, is situated at the entrance of the Baltic-sea, bounded by the Schaggerac-sea, on the north; by the Sound, which separates it from Schonen, on the east; by the Baltic-sea, on the south; and by the strait called the Great Belt, which separates it from the island of Funen, on the west; being of a round figure, near two hundred miles in circumference: the chief town is Copenhagen.

ZEALAND, is also a province of the United Netherlands, consisting of eight islands, which lie in the mouth of the river Scheld, bounded by the province of Holland, from which they are separated by a narrow channel, on the north; by Brabant, on the east; by Flanders, from which they are separated by one of the branches of the Scheld, on the south; and by the German ocean, on the west.

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's law, and the honour of religion.

ZEBRA, in zoology. See *EQUUS*.

ZECHARIAH, a canonical book of the Old Testament, containing the predictions of Zechariah, the son of Barachia, and grandson of Iddo. He is the eleventh of the twelve lesser prophets. Zechariah entered upon the prophetic office at the same time with Haggai, and was sent to the Jews upon the same message, to reprove them for their backwardness in erecting the temple, and restoring divine worship; but especially for the disorder of their lives and manners, which could not but derive a curse upon them. By several notable visions and types, he endeavours to confirm their faith, and establish their assurance concerning God's providence with them, and care over them; and as a proof and demonstration of this, he interperes the most comfortable promises of the coming of the kingdom, the temple, the priesthood the victory, the glory of Christ the Branch. Nor does he for-

get to assure them of the ruin of Babylon, their most implacable enemy. This prophet is the longest and most obscure of all the lesser prophets, his style being interrupted and without connection.

ZEDOARY, in the materia medica, a root, the several pieces of which differ so much from one another in shape, that they have been divided into two kinds, as if two different things, under the names of the long and round zedoary, being on y the several parts of the same root.

Zedoary is to be chosen fresh, sound, and hard, in large pieces; it matters not as to shape, whether long or round; of a smooth surface, and of a sort of fatty appearance within, too hard to be bitten by the teeth, and of the briskest smell that may be; such as is friable, dully, and worm-eaten, is to be rejected.

Zedoary, both of the long and round kind, is brought us from China; and we find by the Arabians, that they also had it from the same place. The round tubera are less frequent than the long, and some of them have therefore supposed them the produce of a different and more rare plant; but this is not so probable as that the general form of the root is long, and the round tubera are only lusus nature, and less frequent in it.

Zedoary, distilled with common water, affords a thick and dense essential oil, which soon concretes of itself into a kind of camphor, and on this oil its virtues principally depend. It is a sudorific, and is much recommended by some in fevers, especially of the malignant kinds. It is also given with success as an expectorant in all disorders of the breast, arising from a tough phlegm, which it powerfully incides and attenuates; it is also good against flatulences, and in the cholick; it strengthens the stomach, and assists digestion; and, finally, is given with success in nervous cases of all kinds.

ZELL, a city of Germany, in the circle of Lower Saxony, capital of the duchies of Zell and Lunenburg, situated at the confluence of the rivers Aller and Fuhle, thirty miles north of Hanover, and forty south of Lunenburg: E. long. 10° , N. lat. $52^{\circ} 52'$.

ZEND, or **ZENDAVESTA**, a book containing the religion of the Magians, or worshippers of fire, who were disciples of the famous Zoroaster. See *MAGI*.

This book was composed by Zoroaster during his retirement in a cave, and contained all the pretended revelations of that impostor. The first part contains the liturgy of the magi, which is used among them in all their oratories and fire-temples to this day; they reverence it as the Christians do the Bible, and the Mahometans the Koran. There are found many things in the zend taken out of the scriptures of the Old Testament, which Dr. Prideaux thinks is an argument that Zoroaster was originally a Jew. Great part of the Psalms of David are inserted: he makes Adam and Eve to have been the first parents of mankind, and gives the same history of the creation and deluge as Moses does, and commands the same observances about clean and unclean beasts, the same law of paying tithes to the sacerdotal order, with many other institutions of Jewish extraction. The rest of its contents are an historical account of the life, actions, and prophecies of its author, with rules and exhortations to moral living. The Mahometans have a sect which they call Zendiktes, who are said to be the Sadducees of Mahometanism, denying providence and the resurrection, believing

believing the transmigration of souls, and following the zend of the magi.

ZENITH, in astronomy, the vertical point; or a point in the heavens directly over our heads.

ZEPHANIAH, a canonical book of the Old Testament, containing the predictions of Zephaniah the son of Cushi, and grandson of Gedaliah; being the ninth of the twelve lesser prophets. He prophesied in the time of king Josiah, a little after the captivity of the ten tribes, and before that of Judah; so that he was co-temporary with Jeremiah. He freely publishes to the Jews, that what increased the divine wrath against them, was their contempt of God's service, their apostasy, their treachery, their idolatry, their violence and rapine, and other enormities: such high provocations as these rendered their destruction terrible, universal, and unavoidable: and then, as most of the prophets do, he mingles exhortations with repentance, as the only expedient in these circumstances.

ZEPHYR, the west wind, or that which blows from the cardinal point of the horizon opposite to the east.

ZEST, the woody thick skin, quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white-wine, as a remedy against the gravel.

ZETETIC METHOD, in mathematics, the method made use of to investigate or solve a problem.

ZEUGMA, a figure in grammar, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZEUS, in ichthyology, a genus belonging to the order of thoracici. The head is compressed, and declines, the upper lip being vaulted over by a transverse membrane; the tongue is subulated; there are seven rays in the gill-membrane; and the body is compressed. The species are four, distinguished by the shape of their tails.

ZEBETHICUS, in zoology. See CASTOR.

ZINGIBER, in botany. See AMOMUM.

ZINK. See CHEMISTRY, p. 90, 106, 143.

ZINZIBER, or ZINGIBER, GINGER, in botany, the naked stalked oval spiked amomum. See AMOMUM, and GINGER.

ZIRANIA, in botany a genus of the monoecia hexandria class. The male has no calix; the corolla consists of a double-valved glume, without any awn. The female has no calix; the corolla consists of a single-valved gluma with an awn; the stylus is bifid; and there is but one seed. The species are two, none of them natives of Britain.

ZIZIPHORA, in botany, a genus of the diandria monogynia class. The corolla is ringent, the superior labium being reflexed and entire; the calix is filiform; and there are four seeds. The species are four, none of them natives of Britain.

ZODIAC, in astronomy, a fascia or broad circle, whose middle is the ecliptic, and its extremes two circles parallel thereto, at such distance from it as to bound or comprehend the excursions of the sun and planets. See ASTRONOMY.

ZOLLERN, a city of Germany, in the circle of Swabia, capital of the county of Zollern, and subject to its count: situated E. long. 8° 55', N. lat. 48° 18'.

ZONE, in geography and astronomy, a division of the terraqueous globe, with respect to the different degrees of heat found in the different parts thereof. See GEOGRAPHY.

ZOOLOGY, the science of animals. See NATURAL HISTORY.

ZOOPHIT, in natural history, a kind of intermediate body, partaking of the nature of a sensitive and a vegetable. See NATURAL HISTORY.

ZOOTOMY, the art of dissecting animals or living creatures, being the same with anatomy. See ANATOMY.

ZUG, one of the cantons of Switzerland, is surrounded by the cantons of Lucern, Zurich, and Switz; and is eighteen miles long, and seven broad.

ZUINGLIANS, a branch of the ancient Christian reformers, or protestants; so called from their author Huldric Zuinglius, a divine of Switzerland, who soon after Luther had declared against the church of Rome; and being then minister of the church at Zurich, fell in with him, and preached openly against indulgences, the mass, the celibacy of the clergy, &c. What he differed from Luther in, concerned the eucharist: for interpreting *hoc est corpus meum*, by *hoc significat corpus meum*, he maintained that the bread and wine were only significations of the body and blood of Jesus Christ; whereas Luther held a consubstantiation.

ZURICH, a canton of Switzerland, bounded by the canton of Schaffhausen on the north, by the canton of Appenzel on the east, by Zug and Switz on the south, and by Bern and Lucern on the west; being fifty miles long, and forty broad. Zurich is also the name of the capital city of this canton, situated E. long. 8° 30', and N. lat. 47° 52'. It is likewise the name of a lake, twenty-four miles long, and three broad; at the fourth end of which the city of Zurich stands.

ZUTPHEN, a city of a county of the same name, in Gelderland, situated on the river Yssel, sixteen miles north-east of Arnheim: E. long. 6°, N. lat. 52° 15'.

ZUYDERSEE, a great bay of the German ocean, which lies in the middle of the United provinces, having the islands of Texel, Flie, and Schelling, at the entrance of it, on the north; the provinces of Friesland, Overijssel, and Gelderland, on the east; Utrecht, and part of Holland, on the south; and another part of Holland on the west. The chief town is Amsterdam.

ZWEIBRUGGEN, a county of the palatinate of the Rhine, in Germany, subject to the duke of Deuxponts.

ZYGÆNA, in ichthyology. See SQUALUS.

ZYGOMA, in anatomy. See ANATOMY, p. 152.

ZYGOMATICUS, in anatomy. See ANATOMY, p. 306.

ZYGOPHYLLUM, in botany, a genus of the decandria monogynia class. The corolla consists of five leaves, and the corolla of five petals; the nectarium consists of ten leaves, covering the germen; and the capsule has five cells. There are 8 species, none of them natives of Britain.

C O R R I G E N D A.

Page 132. col. 1. l. 25, 26. Instead of *from the salivary glands, from smoking, &c.* read, *as to the salivary glands from smoking, &c.*
 P. 510. col. 2. l. ult. For (*ibid.* n^o 2.) read (*Plate CXLVII. fig. 1. n^o 1.*)

METAPHYSICS, l. 10. For *metaphysic*, read *physic*.
 P. 538. col. 2. l. ult. In text of which is always really a diphthong, read, which is always, when long, really a diphthong.

N O T A N D A.

- In the Table of ERRATA at the end of Vol. I. it was said, "That Plate XLVII. represented a different Orrery from the one described." This was a mistake the Printer was somehow led into: for the Orrery there represented is the right one. and corresponds with the description.
- In FLAX-DRESSING. plans of 10 machines relating to that article were referred to, but which several circumstances now render it difficult for the Editors to give. It is therefore hoped these will be dispensed with, as they are not of the most general importance, and the article is sufficiently explained and illustrated without them; and especially as 10 plates more than the proposed number, and 16 pages of letter-press, are given gratis.

D I R E C T I O N S to the B I N D E R.

- Be careful in cutting the book. not to pare too much off the margin; as it was necessary, in several places, particularly in BOOK-KEEPING. to enlarge the page beyond the measure of the rest of the book.
- Title pages for the Three Volumes are printed. Place them respectively at the beginning of the Volume; and after the title in Vol. I. insert the Preface.
- In BOOK-KEEPING, Vol. I. cancel pages 585, 586; and in their place insert the leaves marked with an asterisk and inclosed with parenthesis. viz. (*585) (*586), (*A) (*A), (*B) (*B), (*C) (*C), (*D) (*D), (*E) (*E).
- Insert the Plates as directed below.
